This humble but hardy shrub inhabits the northern latitudes and high mountains of Europe, Asia, and America. On the American continent it extends from Hudson's Bay as far southward as New Jersey, in some parts of which it grows in abundance. It prefers a barren soil, flourishing on gravelly hills and elevated sandy plains. The leaves are the only part used in medicine. They are imported from Europe, but are also collected within our own limits, and the market of Philadelphia is supplied to a considerable extent from New Jersey. They should be gathered in autumn, and only the green leaves selected. In Europe the *uva ursi* is adulterated with the inert leaves of the *Vaccinium Vitis-idaea* (Cowberry, Mountain Cranberry); these may be distinguished by their rounder shape, their revolute edges which are sometimes slightly toothed, and the presence of fine blackish dots or bristly points upon their lower surface. Leaves of the *Chimaphila umbellata*, sometimes found among the *uva ursi*, may be readily detected by their greater length, their cuneiform-lanceolate shape, and their serrate edges.

Arctostaphylos glauca, Lindl., *manzanita*, is a small tree or shrub indigenous in California, where it generally grows in dry and rocky places on the west of the mountain ranges. The leaves are highly esteemed as a remedy in *diarrhœa* and *gonorrhœa*, being used in the form of decoction. Chemically examined by John Henry Flint, they were found to contain arbutin, and 9.8 per cent. of tannin, and the ashes of the incinerated leaves, amounting to 6 per cent., contained potassium, calcium, magne-

sium, and iron. (*A. J. P.*, May, 1873, p. 197.) The fruit of *A. arguta*, Zucco, a Mexican species, is said to be a narcotic poison.

Properties.—*Uva ursi* is inodorous when fresh, but when dried and powdered acquires an odor not unlike that of hay. Its taste is bitterish, strongly astringent, and ultimately sweetish. It affords a light brown, greenish-yellow powder. It is officially described as "obovate or oblong-spatulate, 15 to 30 Mm. long, obtuse, slightly revolute on the margin, tapering into a very short and stout petiole, coriaceous; upper surface dark green, finely reticulate; lower surface slightly pubescent; odor slight; taste strongly astringent and somewhat bitter." *U. S.* Water and official alcohol extract the active principles of *uva ursi*. Among its ingredients are tannic and gallic acids, bitter extractive, resin, gum, fatty matter, a volatile oil, and salts of potassium and calcium. The tannic acid is so abundant that the leaves are used for tanning in Russia. Neither tannic or gallic acid exists in the leaves of the *Vaccinium Vitis-idaea*.

A crystallizable principle was extracted from *uva ursi* by J. C. C. Hughes, to which he gave the name *ursin*, but Jungmann (*A. J. P.*, May, 1871, p. 205) afterwards showed it to be only impure arbutin. Kawaler (*Chem. Gaz.*, 1853, p. 61) obtained *arbutin*, $C_{12}H_{16}O_7$, by precipitating the decoction with lead acetate, filtering, treating the liquid with hydrogen sulphide, again filtering, evaporating to the consistence of syrup, and allowing the product to stand for several days. This gradually assumed the form of a crystalline jelly, which, being placed upon linen so as to allow the mother liquor to drain off, and then pressed, yielded nearly colorless crystals, which were purified by solution in boiling water and treatment with animal charcoal. Arbutin thus obtained is in long, acicular, colorless crystals, united in tufts, and of a bitter taste. It is soluble in water, alcohol, and ether, unchanged apparently by a heat of $100^{\circ} C.$, but fusible at 167° to $168^{\circ} C.$, without action on vegetable colors, and not precipitated by ferric salts or by lead acetate or subacetate. It is a glucoside, being resolvable by emulsin, or more rapidly by boiling with sulphuric acid, into glucose and *hydroquinone*, $C_6H_6O_2$ (*arctuvine* of Kawaler). The occurrence of methylhydroquinone among the products of decomposition led Hlasiwetz and Habermann to give the formula $C_{25}H_{34}O_{14}$ to arbutin, but Schiff showed that this was because arbutin was almost always accompanied by *methylarbutin*, $C_{12}H_{15}(CH_3)O_7 + H_2O$. This compound has been made synthetically by Schiff (*Ber. d. Chem. Ges.*, 1882, p. 1841) by acting upon arbutin with methyl iodide and potassium hydroxide in methyl alcohol solution, and purely synthetically by Michael (*Ber. d. Chem. Ges.*, 1885, p. 118) by the action of methylhydroquinone and acetochlorhydrose. It is decomposed by dilute acids into glucose and methylhydroquinone. Upon heating 1 part of

arbutin with 8 parts of manganese oxide, 2 parts of sulphuric acid, and 1 part of water, it gives off the penetrating odor of quinine. The aqueous solution is rendered blue by a small quantity of solution of ferric chloride, and green by a larger quantity. No precipitate is produced by either acids or alkalis. It blackens ammoniacal solution of silver nitrate after boiling with diluted sulphuric acid, and throws down cuprous oxide from alkaline copper solutions upon heating. It dissolves in sulphuric acid, forming a colorless solution, turning red after a short time; a trace of nitric acid turns this solution yellow-brown. An aqueous solution (1 in 20) is not changed by hydrogen sulphide. A good test for arbutin is that of Julius Jungmann, as follows: When phosphomolybdic acid is added to a solution of arbutin previously rendered alkaline by ammonia or other alkali, a blue color is produced, which is deep when the solutions are strong, but observable even when they are very dilute. (*A. J. P.*, May, 1871, p. 204.)¹ After the extraction of arbutin there is obtained from the mother liquor *ericolin*, $C_{34}H_{56}O_{21}$.² Another crystallizable principle has been discovered by Trommsdorf, who calls it *urson*, $C_{80}H_{148}O_{54}$. It appears to be of a resinous character, although it can be obtained in silky needles, being tasteless and inodorous, insoluble in water, difficultly soluble in alcohol and ether, fusible, at a higher temperature volatilizable, and inflammable in the air. It is obtained by treating uva ursi with a very small quantity of ether by percolation, allowing the ether to evaporate, washing the crystalline extract with ether, and recrystallizing from alcohol. (*A. J. P.*, xxvii. 334.)

A. G. Perkin has obtained from the leaves of *uva ursi* a yellow coloring principle of the composition $C_{15}H_{10}O_7$, crystallizing in glistening yellow needles. On fusion with alkali,

¹ *Arbutin* is somewhat widely diffused in the species of Ericaceæ, such as *Chimaphila umbellata* (L.), Nutt., *Chimaphila maculata* (L.), Pursh, *Epigæa repens*, L., and *Gaultheria procumbens*, L. In some others it has been supposed to exist because among the products of the dry distillation of their extract a principle has been found denominated *hydroquinone*, which is one of the products of the destructive distillation of arbutin; but, as kinic acid yields the same substance in the same way, the inference in relation to the existence of arbutin in the plants is somewhat uncertain. Nevertheless, as kinic acid yields *pyrocatechin* along with *hydroquinone*, while arbutin gives only the latter, a method of distinguishing the two is afforded; the plants from which only *hydroquinone* is obtained probably contain arbutin, while, if both principles are obtained, kinic acid is probably in the plant. (*A. J. P.*, 1874, 314.)

² *Analysis of Vaccinium Vitis-idaea*, or *Red whortleberry*, by Gräber. The berries contain 10.185 per cent. of soluble matter, 4.204 of insoluble matter (cellulose, pectin, etc.), and 85.611 of water. The expressed juice yielded 1.975 per cent. of free organic acid (citric and malic), 5.185 of sugar, 0.476 of tannin, 2.333 of albuminous and pectinaceous substances, suspended fat, etc., 0.216 of inorganic bases (potassa, lime, magnesia, iron), and 89.515 of water. The insoluble residue yielded 0.102 per cent. of ashes containing calcium sulphate and phosphate, silicic acid, and ferric oxide. (*A. J. P.*, 1871, 543.)

³ *Ericolin* is a wide-spread constituent of ericaceous plants, having been found in *Ledum palustre*, L., *Calluna vulgaris* (L.), Salisb., *Rhododendron ferrugineum*, L., etc.; for chemical discussion, see R. Thal, *In. Dis.*, Dorpat, 1883.

phloroglucinol and protocatechuic acid were formed. Though resembling quercetin in these points, it forms deep green solutions with diluted potassium hydroxide. (*A. J. P.*, 1898, 584.)

Uses.—Uva ursi is astringent and tonic, and is thought to have a specific direction to the urinary organs, for the diseases of which it is chiefly used. It alters the color of the urine, and its astringent principle has been detected in that secretion. Though known to the ancients, it had passed into almost entire neglect, until its use was revived by De Haen about the middle of the last century. It has acquired some reputation as an antilithic, and has undoubtedly been serviceable in *gravel*, partly, perhaps, by a direct action on the kidneys and bladder, partly by giving tone to the digestive organs. In *chronic nephritis* it is also a popular remedy, and is particularly recommended when there is reason to conjecture the existence of *ulceration in the kidneys, bladder, or urinary passages. Catarrh of the bladder, incontinence of urine, gleet, leucorrhæa, and menorrhagia* are also among the diseases in which it has occasionally proved serviceable. According to Hues, arbutin in the dose of one grain is a powerful diuretic; that it is free from poisonous properties was shown by Jolonowski, who took in forty-eight hours over two hundred grains of it without discomfort. After large doses the urine varies in color from pale green to dark greenish brown. The discoloration is due to the breaking up of the arbutin in the body into glucose and hydroquinone, the change probably occurring in the kidneys. There is considerable clinical testimony to show that arbutin is a useful remedy in *cystitis* when given in doses of ten to fifteen grains a day. The influence of the drug has been supposed to be due to its conversion into hydroquinone, which, as is well known, is a powerful disinfectant and antiferment. H. Paschke states that only a small portion of the arbutin is changed into hydroquinone, and this is confirmed by Laurentz. The extract (see page 468) formerly official contains only three and a half per cent. of arbutin and sixteen per cent. of tannic acid; there is also a volatile oil in uva ursi, so that arbutin cannot be considered fully to represent the drug.

Dose, of the powder, from twenty grains to a drachm (1.3 to 3.9 Gm.), to be repeated three or four times a day; but the fluidextract is always preferred.

VALERIANA. U. S. (Br.)

VALERIAN

(vā-lē-rī-ā'nā)

"The dried rhizome and roots of *Valeriana officinalis* Linné (Fam. Valerianaceæ)." U. S.

"The dried erect rhizome and roots of *Valeriana officinalis*, Linn. Collected in the autumn." Br.

Valeriana Rhizoma, Br.; Valerian Root; *Radix Valeriana Minoris*, R. *Valeriana Sylvestris*, R. *Valeriana Montana*; Common, Garden, Cat's or Great Wild Valerian, All-heal, Summer Heliotrope, Herb Bennet, Vandal Root; *Valeriana officinale*, Fr. *Cod.*; *Racine de Valériane*, *Valériane*, Fr.; *Radix Valerianae*, P. G.; Baldrian, Wilde Baldrianwurzel, Baldrianwurzel, G.; *Valeriana*, It.; *Valeriana* (Rhizoma de), Sp.

For *Valeriana Indica Rhizoma*, Br. Add., see PART II.

Valeriana officinalis, L., *Sp. Pl.* (1753) 31; Willd., *Sp. Plant.* i. 177; B. & T. 146.—The official or great wild valerian is a large, handsome, herbaceous plant, with a perennial root, and an erect, round, channelled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stems are attached by short, broad sheaths; the radical leaves are larger and stand on long footstalks. In the former the leaflets are lanceolate and partially dentate, in the latter elliptical and deeply serrate. The flowers are small, white or rose-colored, agreeably odorous, and disposed in terminal corymbs interspersed with pear-shaped bracts. The number of the stamens is three. The fruit is a capsule containing one oblong-ovate, compressed seed. The plant is a native of Europe, where it grows either in damp woods and meadows or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. Dufresne makes four, of which three prefer marshy situations. The variety which affects a dry soil (*sylvestris*, L. Ph.) is not more than two feet high, and is distinguished by its narrow leaves. It has been generally believed to be superior to the others in medicinal virtue, but A. Buchner has demonstrated that the dried roots of the variety which grows in low moist grounds are in no respect inferior. (*Ph. Cb.*, June, 1852, 429.)¹

The root should be collected in spring, before the stem begins to shoot, or in the autumn, when the leaves decay. It should be dried quickly, and kept in a dry place. It consists of numerous, long, slender, brittle, cylindrical, thick-barked rootlets, issuing from a tuberculated

rhizome; it is officially described as "from 2 to 4 Cm. long, and 1 to 2 Cm. thick, upright, subglobose or obconical, truncate at both ends, brown or yellowish-brown, internally whitish or pale brownish, with a narrow circle of white wood under the thin bark. Roots numerous, slender, brittle, brown, with a thick bark, and slender, ligneous cord. Odor peculiar, becoming stronger and more unpleasant on keeping the drug; taste camphoraceous and somewhat bitter." U. S. As brought to this country, it frequently has portions of the stem attached. The English is superior to that from the continent of Europe. Valerian of good quality has been produced by the Shakers at Enfield, New Hampshire, also in Northern Vermont and New York. Thomas Doliber obtained from the American root 28.97 per cent. of alcoholic extract, and from the English 17.59 per cent., and stated that the native drug had, in our market, almost superseded the European. (*A. J. P.*, 1867, p. 70.)

Properties.—The color of the root is externally yellowish or brown, internally white. The powder is yellowish gray. The odor, which in the fresh root is slight, in the dried is strong and highly characteristic, and, though rather pleasant to many persons, is very disagreeable to others. Cats are strongly attracted by it. The taste is at first sweetish, afterwards bitter and aromatic. Valerian yields its active properties to water and alcohol. Trommsdorff found it to consist of 1.2 parts of volatile oil, 12.5 of a peculiar extractive matter, soluble in water, insoluble in ether and alcohol, and precipitated by metallic solutions, 18.75 of gum, 6.25 of a soft odorous resin, and 63 of lignin. Runge found in it a peculiar fixed acid, which produced with bases white salts, becoming green on exposure to the air. (*Chem. Gaz.*, No. 170, p. 452.) Of these constituents the most important is the volatile oil.¹ It is of a pale greenish color, of the sp. gr. 0.934, with the pungent odor of valerian, and an aromatic taste. It becomes yellow and viscid by exposure. Bruylants (*Ber. d. Chem. Ges.*, 1878, p. 449) has obtained from oil of valerian, 1st, a hydrocarbon or terpene, $C_{10}H_{16}$, boiling at $157^{\circ} C$; 2d, a liquid compound, $C_{10}H_{18}O$, which by means of chromic acid affords common camphor, and formic, acetic, and valeric acids, which are met with in old valerian root, owing no doubt to the slow oxidation of the compound $C_{10}H_{18}O$; 3d, a crystalline compound

¹ *Valeriana mexicana*. DC.—According to the *Nueva Farmacopea Mexicana*, the roots of this plant contain a large percentage of valeric acid, which they yield readily and economically. In Mexican commerce they are said to occur in slices or fleshy disks about four centimeters or more in diameter, or in voluminous tubercles. Externally the color is grayish-yellow, internally yellow; the odor is strong and disagreeable, the taste bitter. R. McLaughlin (*A. J. P.*, 1893, 329) found 3.3 per cent. of oil in the Mexican valerian root. (See also *Schim. Rep.*, April, 1897.) *Japanese Valerian*. *Kesso root*.—This, formerly believed to be the product of *Patrinia scabiofolia*, Link, is now thought to be obtained from a variety of *V. officinalis*. It yields a volatile oil. (*P. J.*, xx, 337, xxi, 1069.) The rhizome sometimes known as *Valeriana Radix Majoris* is obtained from *V. Phu*, L., of Southern Europe and Western Asia. It is from 4 to 6 inches long, $\frac{1}{2}$ inch in thickness, brown, annulated with numerous yellowish roots, and a feeble, valerian-like odor and taste.

² *Oilum Valerianæ*. U. S. 1880. *Oil of Valerian*. (*Essence de Valériane*, Fr.; *Baldrianöl*, G.)—This volatile oil is obtained from the root of *Valeriana officinalis* by the usual process of distillation with water. According to Zeller, the dried root of the best quality yields 1.64 per cent. of the oil. Very good oil has been distilled from the root cultivated in this country. As first procured, it is of a pale greenish color, of the sp. gr. 0.934, with a pungent odor of valerian, and an aromatic taste. Upon exposure it becomes yellow and viscid. "A slightly acid reaction. Sp. gr. about 0.950. It is readily soluble in alcohol." The oil of valerian exercises the same influence as does the root on the nervous system, and is frequently administered as a substitute for it, in the dose of four or five minims (0.25 to 0.3 Cc.).

of the same composition, which in the root is probably combined with the three organic acids mentioned, forming corresponding esters with them; 4th, at from 285° to 290° C., a greenish, syrupy oil, which when rectified is colorless, and seems to have the composition of a *borneol oxide*, $(C_{10}H_{17})_2O$. Schimmel & Co. (*Schim. Rep.*, April, 1897) summarize the most recent researches upon valerian oil from different sources. In the oil from Dutch and Thuringian roots, the amount varying from 0.5 to 1 per cent., they find pinene, camphene, borneol, bornyl formate, bornyl acetate, and *bornyl isovalerate*, together with a sesquiterpene and an alcohol, $C_{10}H_{18}O_2$. In the oil from Japanese roots (amounting to from 6 to 6.5 per cent.) (*Kesso oil*), they find pinene, camphene, dipentene, terpineol, borneol, bornyl acetate, bornyl isovalerate, and kessyl acetate. Trommsdorff ascertained the existence in the oil of *valeric acid*.

This acid is a colorless volatile liquid, of an oleaginous consistence, having an odor analogous to that of valerian, and a very strong, sour, disagreeable taste. It is soluble in thirty parts of water, and in all proportions in ether and alcohol. It combines with salifiable bases, forming soluble salts, which retain, in a diminished degree, the odor of the acid. (*J. P. C.*, xx. 316.) The results of Bruylants just given show that the acid does not pre-exist in the oil, but is produced by the decomposition of its borneol ester. Valeric acid is obtained by distilling the impure oil with magnesium carbonate, decomposing by sulphuric acid the magnesium valerate which remains, and again distilling. The following process by T. and H. Smith of Edinburgh, avoids the inconvenience of distilling so bulky a root as valerian, while it answers the same purpose as that of Rabourdin. Boil the root for three or four hours with rather more than its bulk of water in which an ounce of sodium carbonate is dissolved for every pound of the root, replacing the water as it evaporates. Express strongly, and boil the residuum twice with the same quantity of water, expressing each time as before. Mix the liquids, add two fluidrachms of strong sulphuric acid for every pound of the root, and distil until three-fourths of the liquid have passed over. Neutralize this with sodium carbonate, concentrate the liquid, decompose the sodium valerate contained in it by sulphuric acid, and collect the valeric acid set free, by a separator, funnel, or by distillation. (*A. J. P.*, xvii. 253.) Lefort obtains the acid by the rapid oxidation of the volatile oil. He distilled 100 parts of the root with 500 of water, 10 of sulphuric acid, and 6 of potassium dichromate, and in this way procured a larger proportion of acid than by any other process. (*J. P. C.*, 3e sér., x. 194.)

The roots of *Valeriana Phu*, L., and *V. dioica*, L., are said to be sometimes mingled with those of the official plant. According to

Ebermayer in Germany various ranunculaceous roots are a dangerous adulterant of valerian; they may be readily detected by their want of the peculiar odor of the official root. According to M. O. Ravell, the valerian in the markets of Paris is largely adulterated with the roots of *scabious* (*Scabiosa succisa*, L., and *S. arvensis*, L.). They are shorter than the genuine root, with larger radicles, less rough, little or not at all striated, very brittle, with a white amylaceous fracture. The roots are inodorous in themselves, but are very apt to acquire odor from contact with the valerian. (*J. P. C.*, xxvi. 209.)

Uses.—Valerian is gently stimulant, with an especial direction to the nervous system, but without narcotic effects. In large doses it produces a sense of heaviness and dull pain in the head, with various other effects indicating nervous disturbance. The oil, largely taken, is said by Barailer, from his own observation, to produce dulness of intellect, drowsiness ending in deep sleep, reduced frequency of pulse, and increased flow of urine. (See *A. J. P.*, 1861, p. 239.) It is useful in cases of irregular nervous action, when not connected with inflammation or an excited condition of the system. Among the complaints in which it has been particularly recommended are *hysteria*, *hypochondriasis*, *hemicrania*, and *low forms of fever*, attended with restlessness, morbid vigilance, or other nervous disorders. As the virtues of valerian reside chiefly in the volatile oil, the medicine should not be given in decoction or extract. The distilled water is used on the continent of Europe, and the volatile oil is occasionally substituted with advantage for the root. The dose of the oil is four or five minims (0.25 to 0.3 Cc.). Valeric acid also has been used internally. (See *Valeric Acid*, PART II.) Landerer says that, in his experience, the acid prepared from the root is preferable therapeutically to the artificial acid; this preference may be due to the presence of impurities, having medicinal properties, which are found in the acid from the root.

VANILLA. U. S.

VANILLA

(va-nil'la)

"The cured, full grown, but immature fruit of *Vanilla planifolia* Andrews (Fam. *Orchidaceæ*)."
U. S.

Vanille, Fr. Cod.; Fructus Vanille, P. G.; Vanille, G.

Vanilla planifolia, Andrews, *Bot. Repository*, t. 538 (1808); B. & T. 272.—This is a fleshy, dark green, perennial climbing plant, with a very long, smooth, dark green stem, much branched, and furnished at the nodes

with aerial roots, which cling to the tree or the wooden framework supporting the plant. The dark green, tough leaves are alternate, oval, sessile, attenuate at the apex, fleshy, and veinless. The pale greenish-yellow, sessile flowers are about two inches in diameter, and occur in loose, axillary racemes of eight or ten. The fruit is a slender pod, seven or eight inches long, filled with an oily mass containing numerous small, black, shining seeds.¹ Doubts, however, exist whether commercial vanilla is entirely derived from this species, and the United States Pharmacopœia formerly ascribed it to *V. aromatica*, Swartz, considered by some botanists to be a variety of *V. planifolia*, from which it is distinguished by its ovate-oblong, nerved, opposite leaves, its waxy sepals, its acute lip, and its very long cylindrical capsules. According to R. A. Rolfe, *V. Pompona*, Schiede, yields the Guadeloupe variety, and *V. Gardneri*, Rolfe, is said to yield Brazilian and Bahia vanilla. *V. appendiculata*, Rolfe, and *V. odorata*, Presl., produce aromatic fruits, but are not known to be cultivated, while *V. phœantha*, which possesses but little perfume, is under cultivation at Jamaica and Trinidad. (*Kew Bulletin*, No. 104, 169.) *V. guayanensis* and *V. palmarum* are also said to yield an aromatic fruit. (See also below.)

This plant is a native of the West Indies, Mexico and South America, but is now extensively cultivated. The plant does well from the sea-level up to two thousand feet of altitude, requiring for its perfection, however, a moist, hot climate, with an habitual dry summer spell which seems to be necessary to bring good flowering. It is propagated by means of cuttings, sometimes two or three feet in length but preferably from ten to twelve feet long taken from growing shoots; these are planted after the dry season is over and should produce flowers in two years. Preferably placed upon trees, but sometimes on long stakes, trellises, wire supports, etc., the slip is placed with one end on the ground, covered with leaves or some light top dressing. In many cases the vines are planted so closely as scarcely to leave room for cultivators to pass, but it has been found that under these circumstances the vanilleries are especially liable to destructive fungous diseases. As the flower does not fertilize itself, fertilization (pollination) by hand

is necessary; it is usually performed by women and children. It is said that a fairly trained workman can fecundate over one hundred flowers per hour. In most localities no more than thirty fertilized flowers should be left to a plant. The pods reach their full size in from five weeks to eight months, according to the altitude of the locality and to the amount of shade. The first indication of ripening is a slight yellowing of the whole pod; as soon as this occurs the pods should be picked, and sorted, and the curing process commenced. If left to ripen further the pods are prone to split and otherwise deteriorate. For the purpose of curing them the pods are kept in a heated room for some days (about 110° F.), then transferred to a cooler one (90° F.), and finished at ordinary temperature. During the process, which lasts some months, there is a loss of 70 to 80 per cent. of weight. For details as to culture, see *Bulletin* 21, 1898, U. S. Department of Agriculture, Division of Botany. The practice of curing the beans by placing them under blankets in the sun is still in vogue, but that of using a regulated artificial heat is more certain, and it is the modern method.

When thoroughly cured the beans are sorted and tied into bundles, which are wrapped in sheet lead or placed in small metallic boxes. In doing this it is essential that the bundle be wrapped in a thin vegetable parchment paper, as chemical action occurs when the beans come in contact with the metal.

Fruits which have not been picked early enough are inferior and are frequently cut into short pieces and sold as "cuts." If by chance the fruit should be picked too early the quality of the resulting product is distinctly inferior. The fruit as first picked has no aroma, the *vanillin* during the process of curing being produced from the glucoside *coniferin* in the interior of the fruit. This was shown to be converted into *coniferyl alcohol* and glucose, and the former of these subsequently changed into *vanillin*.

The cultivation of vanilla has extended from South America throughout the tropics, so that at present although the wild plant is abundant in the Mexican States of Vera Cruz and Oaxaca the vanilla of the markets comes almost exclusively from vanilleries. Holland is supplied from the Java plantations; France from Tahiti, Madagascar, Réunion, Guadeloupe, and other of her colonies. From Mauritius and the Seychelles the product goes to London. In the markets most of the varieties are known by the name of the country in which they are produced. The finest of the varieties is the Mexican although of recent years the Bourbon beans have so improved that they almost rival it in strength and flavor. At present the Mexican bean is sold at somewhat less than double the price of the Bourbon; the Bourbon at almost double the price of the Tahiti, the latter bean being commonly much injured by carelessness in the process of curing.

¹ The following account of the structure of vanilla fruit is adapted from that of S. E. Jelliffe. The transverse section of the vanilla bean displays a thick-walled, irregular triangular cavity, into which the placenta, supporting two rows of fine black seeds, projects. The wall of the ovary is lined with minute papillæ bearing unicellular papillose hairs, which project into the central cavity and are believed to secrete the materials out of which the *vanillin* is elaborated. Beneath the epicarp or external part of the fruit is a lax tissue, in which there is an oily substance with the characteristics of *vanillin* and numerous fine acicular crystals of calcium oxalate. The polygonal mesocarpal cells are for the most part finely pitted, some irregularly marked. The vascular bundles of the mesophyll are irregularly scattered or radially or tangentially arranged. Spiral ducts are abundant, annular ducts few. In the tissue of the mesophyll irregular resinous masses and prisms of *vanillin* occur.

Of *Mexican vanilla*,¹ the first quality occurs in pods from eight to ten inches long, flattened, two-eighths to three-eighths of an inch in diameter, with the lower end slightly attenuated, the upper end gradually tapering for about a quarter of the length of the pod, usually curved and slightly twisted near the point. The color is dark brown, the pods fairly plump, the surface ridged longitudinally, and with an incrustation of fine crystals beginning at the ends, gradually extending; when fresh somewhat viscid, but always roughish to the touch. For an interesting account of the Mexican vanilla plant by Charles E. Hires, see *A. J. P.*, 1893, 576.

Bourbon vanilla, produced in the Isle of Réunion to the amount of 200,000 pounds a year, resembles Mexican vanilla, but is scarcely so long in the tapering portions, is of a dark-brown almost black color, is not so firm as the Mexican, has the surface smooth and waxy, and soon becomes covered with a coating of acicular crystals known as "frost." The odor of this vanilla is said to resemble that of Tonka bean rather than that of Mexican vanilla.

The *Seychelles* and *Mauritius vanilla* (inferior Bourbon of the trade) has the pods about six inches in length, not over a quarter of an inch in width, and characterized by the pale color, the faint odor, and a smooth but not waxy surface.

South American or *Guadeloupe vanilla* resembles the Mexican bean, but is usually recognizable, when the bean is entire, by the latter being broad and flattened, usually half an inch or more wide, slightly tapering at the lower end, and at the upper sharply attenuated an inch or so at the point. It has a reddish-brown color, and is of a rank odor. It is very pulpy,

with a surface intermediate in feel between the Bourbon and the Mexican, and having but few crystals. One variety of this vanilla, sold under the name of *vanillons*, has the odor of heliotrope and is much used by perfumers and tobacco manufacturers. See foot-note.

Tahiti vanilla, "*transplanted Mexican vanilla*," has its pods from six to seven inches long, flat, from three-eighths to half an inch wide, with a reddish-brown color. They are almost destitute of vanilla flavor, and have an odor suggesting heliotrope. It is said they contain piperonal and also vanillin. (*Ph. Cb.*, 45.)

Java vanilla, which is almost exclusively consumed in Holland, has a pod from four to six inches long, with a flavor as fine as that of the Mexican bean, and a much stronger odor.

The importations of vanilla beans into the United States for 1904 amounted to 550,316 lbs., valued at \$1,424,763, and for 1905 to 608,576 lbs., valued at \$872,124.

Properties.—Vanilla is officially described as "linear, narrowed, and bent or hooked at the rather oblique base, about 15 to 20 Cm. long and about 7 Mm. thick; externally blackish-brown, longitudinally wrinkled, glossy, frequently covered with an efflorescence of vanillin in acicular crystals, flexible and tough, 1-celled, containing a blackish-brown pulp and numerous minute, blackish, ovoid and flattened seeds; odor and taste characteristic and very agreeable." *U. S.* Vanilla beans from which the vanillin has been removed by means of a solvent are sometimes offered for sale. The fraud is to be detected by the absence of flavor and odor. Such beans, and also beans of an inferior quality, are sometimes "improved" in appearance and in odor by the use of benzoic acid. For the detection of this fraud the pharmacist should avail himself of the fact that while the crystals of benzoic acid are flattened and rhomboidal and generally lie upon the bean, those of vanillin are usually acicular and stand out at right angles from the surface of the fruit. The absence of the crystalline coating on the vanilla beans seems to be no proof of inferiority, for Henri Lecomte affirms that it is not rarely absent in the best Mexican bean. (*B. Sc. Pharm.*, 1901.)

According to Bucholz, vanilla does not yield volatile oil when distilled with water, and the aroma appears to depend on chemical changes which may take place during and after the curing of the fruit. Many years since, vanilla was analyzed by Bucholz and Vogel, the former of whom found in it a disagreeable-smelling fixed oil, a soft resin having a feeble odor of vanilla when heated, a bitterish extractive resembling tannin, sugar, starch, and benzoic acid. But the characteristic odorous principle was not isolated until Gobley obtained *vanillin* by acting on vanilla with solvents (see *Vanillinum*). Although the latter substance has been largely manufactured, it does not take the place of the preparations of *vanilla*, the flavor and odor of the latter being

¹ Of the Mexican vanillas the most valuable variety, called *ley*, or *vainilla mansa*, by the Spaniards, consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines thick, nearly straight, narrowing towards the extremities, bent at the base, shining and dark brown externally, wrinkled longitudinally, soft and flexible, and containing within their tough shell a soft black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong, agreeable odor, and a warm, aromatic, sweetish taste. The interior pulpy portion is most aromatic. In it are more or less numerous, minute crystals. Another variety, called *vainilla simarona* by the Spaniards, is smaller, of a lighter color, and less aromatic. The pods are said to be very dry and to contain no vanillin. (*Nueva Farmacopea Mexicana*.) According to Schiede, it is yielded by a distinct species, the *Vanilla sylvestris*. Schiede. A third variety is the *vainilla pompona* of the Spaniards (*boba vainilla*, or *plátano vainilla*). In this, the pods are from five to seven inches long, from six to nine lines broad, shaped somewhat like a plantain, almost always open, very dark brown or nearly black, soft, viscid, and of a strong odor. Schiede states that it is the product of the *Vanilla Pompona*, Schiede. The variety *vainilla veraoate* is said to be derived from pods gathered long before maturity. (*Nueva Farmacopea Mexicana*.) The *vainilla pompona* of the Spaniard is evidently the *vanillons* of European commerce, which are usually from 4 to 5 inches long and from $\frac{3}{8}$ to 1 inch in diameter, frequently sharply angled, brown to reddish-brown in color, usually split open and free from efflorescence. Owing to the transverse markings by twine with which they have been wrapped during the process of curing, the beans have a peculiar twisted appearance. Their odor, which resembles that of heliotrope, is due to the presence in them of *heliotropin*, in lieu of *vanillin*.

greatly preferred. It passes with water in distillation. If vanilla, finely divided, be distilled with water, a turbid liquid passes, which becomes clear by agitation with ether, and the ether on evaporation yields crystals of vanillin. Vanilla, in the fresh state in which it is gathered, does not in the least possess the characteristic fragrant odor. H. Lecomte (*J. P. C.*, 1903, 343) studied the conditions which bring about the formation of vanillin. According to his researches, there exist in the vanilla plant two ferments, which differ in a marked degree from each other in their functions. The one, an oxydase, is present in the individual organs of the plant, such as the leaves, shoots and their aqueous extracts, in the green and ripe fruit, and in the prepared commercial fruit. Lecomte detected it in the organs of plants of different origin, by means of G. Bertrand's reactions. At the same time, the presence of manganese salts was observed in all products, which renders it not impossible that they stand in some relation to the above-named ferment. The second ferment is contained in the sap of the vanilla, and acts as a hydrolyzing ferment. With regard to the mechanical treatment of vanilla, it would appear in the first instance as if it counteracted the function of the ferment. It consists, as is well known, of the immersion of the fruit during twenty seconds in water at 85° C. (185° F.), a manipulation which might bring about the destruction of the ferment. But the author has convinced himself that a temperature of about 50° C. (122° F.), such as the interior of the fruit probably only reaches during the short duration of the process, really promotes the function of the oxydase. Both ferments, the oxydase as well as the one possessing the hydrolytic action, appear to be necessary for the formation of vanillin in the plant, and their action may possibly be explained thus: During the preparation, the confiferin produced by the plant is split up into glucose and conferyl alcohol. This process would explain also the occurrence of grape-sugar in vanilla. The oxydase then converts the conferyl alcohol into vanillin. Tiemann and Haarmann obtained from Mexican vanilla 1.69 per cent. of vanillin, from Réunion vanilla 2.48 per cent., from Java vanilla 2.75 per cent. Stokeby found in vanilla, resin, wax, a fixed oil, a brown resinous matter, tannic acid changing the salts of iron to green, gum, sugar, phosphates, and sulphates: hydrochloric acid separated from it oxalic acid, and potassium hydroxide, humic acid. (*J. P. C.*, 4e sér., iii. 76, 1866; see also paper by Clay W. Holmes, *Proc. A. Ph. A.*, 1887, 526.)

Uses.—See *Vanillinum*.¹

VANILLINUM. U. S.

VANILLIN

(vā-nīl-lī'nūm)

"Methylprotocatechuic aldehyde [$C_6H_5.OH.OCH_3.CO.H$ 4:3:1], occurring naturally in vanilla, or made artificially from several ortho-dihydroxybenzene derivatives." *U. S.*

Vanilline, *Fr. Cod.*; Vanillin, Vaniliekampher, Protocatechuinaldehydmethylæther, *G.*

Preparation.—Vanillin was first obtained from vanilla by Goble, who, by exhausting vanilla with 85 per cent. alcohol, evaporating the resulting tincture to an extract, softening this with water, and agitating in a flask with ether so long as it gave color to that fluid, then evaporating the ethereal liquid and treating the residue with boiling water, obtained on the evaporation of the water a crop of crystals having the odor of vanilla. Purified by treatment with animal charcoal and recrystallization, the principle appeared in the form of colorless, long, four-sided needles terminated by two faces. It has a strong odor of vanilla, with a hot, biting taste, and is frequently seen in acicular crystals upon the external surface of the bean. This compound, for which Goble

resemble those of cholerine. That the attacks have not simply been cholera morbus induced by the ingestion of cold ices is shown by the fact that many of the flavored dishes were pies and even simple farinaceous puddings. Elaborate chemical investigations have proved the absence of metallic poisons in the ingesta. Schroff believes the poison to be cardol derived from the oil of cashew nut placed upon the vanilla pod to preserve it, but there does not seem to be any proof of this, and it is stated that cardol could not be found in the vanilla pods obtained from the Vienna café at Berlin, where poisoning had occurred. (*P. J.*, 1874, p. 853.) Again, it has been believed that the poisoning was the result of copper derived from vessels in which the ice cream had been preserved, but chemical analysis has disproved this. Certain chemists have been inclined to suppose that the poisoning was caused by ptomaines or other products of decomposition of the cream before freezing. Layot (*J. P. C.*, x.) believes that the poisoning is really due to the vanilla, and especially to an inferior variety of bean known as "vanillon," the pods of which are free from rime, soft, viscous, and nearly always open. If, however, it be correct, as asserted (*P. J.*, xv. 241), that the poisoning has been caused by ice cream flavored with artificial vanillin, it is almost certain that the symptoms are due to alterations in the cream itself. This is confirmed by the studies of V. C. Vaughan, who, in 1885, succeeded in isolating from cheese a peculiar poisonous ptomaine, *tyrotoxin*. (See *A. J. P.*, 342, 1886.) Subsequently, Vaughan obtained the same poison from milk, and in June, 1886, melted ice cream taken from a mass which had produced serious poisoning in eighteen persons, with some of the vanilla which had been used in flavoring the cream, was submitted to him for analysis. (See *A. J. P.*, xvi. 452.) The ingestion of the vanilla in doses of thirty drops of an extract failed to develop in Vaughan or his assistants any symptoms, and he was able to separate the tyrotoxin from the ice cream itself and to poison animals with it. H. C. Wood has seen violent poisoning, with gastro-intestinal irritation and symptoms resembling those of the so-called vanilla poisoning, produced by the ingestion of stale cream puffs in which no vanilla had been put, and it is more than probable that in most cases of the so-called vanilla poisoning tyrotoxin or some allied substance is the cause of the symptoms. If the case reported by Rosenthal be accurately stated (*P. J.*, xv. 24), it must be allowed, however, that in some instances the vanilla itself is at fault.

¹ *Vanilla Poisoning.*—Many years ago, Orfila recorded cases of poisoning by the eating of vanilla ices, and recently many cases have occurred both in Europe and in this country. The symptoms are those of intense gastro-intestinal irritation, and closely

proposed the name *vanillin*, is now recognized as the methyl-ether of protocatechuic aldehyde,

occur somewhat diffused in the vegetable kingdom, being found in the sugar beet and in the wood-tissue of many plants. It forms crystalline needles fusing at 80° to 81° C., difficultly soluble in cold water, readily soluble in hot water, easily soluble in alcohol and ether, chloroform, and carbon disulphide. It oxidizes slowly in damp air to *vanillic acid*, $\text{C}_8\text{H}_5\text{O}_4$; when heated with diluted hydrochloric acid to 200° C., it breaks up into methyl chloride and protocatechuic acid. Tiemann and Haarmann (*Ber. d. Chem. Ges.*, 1874), who first ascertained the true character of vanillin, also found that it could be made synthetically from *coniferin*, a glucoside contained in the cambium layer of the pine. This coniferin, $\text{C}_{16}\text{H}_{22}\text{O}_8 + 2\text{H}_2\text{O}$, or the compound $\text{C}_{10}\text{H}_{12}\text{O}_8$, which with glucose results from its decomposition, is oxidized by sulphuric acid and potassium dichromate with the production of vanillin. Artificial vanillin was made in this way from coniferin under Tiemann and Haarmann's patents, and was made by Reimer and Tiemann from guaiacol by heating it with sodium hydroxide and chloroform, but it is now made from *eugenol*,

ized, when *vanillin*, $\text{C}_6\text{H}_5 \begin{cases} \text{OH} \\ \text{OCH}_3 \\ \text{CHO} \end{cases}$, is formed.

A larger yield is obtained if the isoeugenol is first acetylated, as the acetisoeugenol is more stable under the influence of oxidizing agents. The product acetvanillin is readily decomposed, with the liberation of the vanillin. The oxidation is effected by a variety of oxidizing agents. Sodium peroxide has been used with success, or more recently the isoeugenol sodium has been oxidized at the positive pole of an electrolytic cell, using an alkaline hydroxide as the cathode liquid. Oil of cloves is therefore used as a basis for the manufacture of artificial vanillin.

Properties.—It is officially described as in "fine, white, crystalline needles, having the odor and taste of vanilla, and having an acid reaction. Soluble in about 100 parts of water at 25° C. (77° F.), and in 15 parts at 80° C. (176° F.). It is easily soluble in alcohol, ether, glycerin, or chloroform. When heated to between 80° and 81° C. (176° and 177.8° F.), it melts, and at 285° C. (545° F.) it can be distilled without decomposition in a current of carbon dioxide, leaving no residue. It is easily soluble in aqueous solutions of alkali hydroxides, and from the combinations thus

formed it is precipitated at once by the addition of acids. An aqueous solution of Vanillin gives, with ferric chloride T.S., a blue color; if the mixture be boiled, the blue color changes to brown, and on cooling a white precipitate of dihydro-divanillin separates. Vanillin is extracted completely from its solution in ether by shaking with a saturated aqueous solution of sodium bisulphite, from which solution it is precipitated by the addition of sulphuric acid. An aqueous solution of Vanillin will give, on the addition of lead acetate T.S., a white precipitate of a lead compound of vanillin, soluble in hot water, and crystallizing, on cooling, in scales. On warming 0.1 Gm. of Vanillin with concentrated alcoholic solution of sodium hydroxide, adding chloroform and again warming, it should not give an odor of phenylisocyanide (absence of *acetanilide*)."
U. S.

Uses.—According to Grasse, vanillin produces in frogs spinal convulsions followed by paralysis due to a direct action upon both the spinal cord and motor nerves. It has been suggested as a stomachic and excito-motor given in doses of three-fourths of a grain (0.048 Gm.). (*A. Pharm.*, Aug. 1896.) Neither it nor vanilla, however, are used for other than flavoring purposes. The fact that while the vanilla beans have steadily risen in price for a number of years that of the artificial vanillin has enormously fallen, indicates that as a flavoring agent vanillin is not equal to the natural product. It is said that articles flavored with it leave a peculiar, disagreeable after-taste and retain their flavor only a very short time.

VERATRINA. U. S., Br.

VERATRINE

(vēr-ā-trī'nā)

"A mixture of alkaloids obtained from the seed of *Asagraea officinalis* (Chamisso and Schlechtendal) Lindley (Fam. *Liliaceae*). It should be kept in well-stoppered, amber-colored vials." *U. S.* "An alkaloid, or mixture of alkaloids, prepared from cevadilla, the dried ripe seeds of *Schönocaulon officinale*, *A. Gray.*" *Br.*

Veratria, *U. S.* 1870; Veratrine, *Fr. Cod.*; Veratrinum, *P. G.*; Veratrin, *G.*; Veratrina, *It., Sp.*

"Cevadilla of commerce, 2 pounds (Imperial) or 1 kilogramme; Distilled Water, Alcohol (90 per cent.), Solution of Ammonia, Hydrochloric Acid, of each a sufficient quantity. Macerate the cevadilla with half its weight of boiling Distilled Water, in a covered vessel, for twenty-four hours; remove the cevadilla; squeeze it; dry it thoroughly in a warm place; then beat it in a mortar, and separate the seeds from the capsules. Reduce the seeds to powder; moisten the powder with the Alcohol; pack firmly in a percolator; pass the Alcohol through the marc until the percolate ceases to be colored; concentrate the alcoholic solution by

distillation, so long as no deposit forms, and pour the residue, while hot, into twelve times its volume of cold Distilled Water; filter through calico; wash what remains on the filter with Distilled Water, until the filtrate ceases to precipitate with Solution of Ammonia. To the filtrate add Solution of Ammonia in slight excess; let the precipitate completely subside; pour off the supernatant liquid; collect the precipitate on a filter; wash it with Distilled Water until the filtrate passes colorless; distribute the moist precipitate through *twelve fluid ounces* (Imp. meas.) or four hundred cubic centimetres of Distilled Water; add gradually, with diligent stirring, sufficient Hydrochloric Acid to make the liquid feebly but persistently acid; add *sixty grains* or four grammes of the purified animal charcoal of commerce; digest with moderate heat for twenty minutes; filter; allow the liquid to cool; add Solution of Ammonia in slight excess, and, when the precipitate has completely subsided, pour off the supernatant liquid; collect the precipitate on a filter and wash it with cold Distilled Water until free from chloride; dry the precipitate, first by imbibition with filtering paper, and then by the application of warmth." *Br.*

The U. S. P. (8th Rev.) very properly does not give a process for veratrine, as it cannot be made profitably by the pharmacist. (See *Sabadilla*, PART II.)

In the U. S. process of 1870¹ the first step is to obtain a tincture of *cevadilla*, which is evaporated to the consistence of an extract. This contains the veratrine combined with a vegetable acid, probably gallic, as it exists in the seeds. From the extract the alkaloid is dissolved by the acidulated water, which at the same time converts it in great measure into a sulphate, a small portion possibly remaining in the solution combined with an excess of the natural acid. The magnesia combines with the acids and throws down the veratrine,

which is then taken up by alcohol and again yielded in a purer state by evaporation. To purify it still further, it is redissolved in water by the agency of sulphuric acid, is submitted to the action of animal charcoal, and is finally precipitated by ammonia. In the British process, the tincture is concentrated until it begins to let fall a precipitate, and is then poured into water, which throws down the resin and oil with a portion of the coloring matter and retains the salt of veratrine. This is then decomposed by ammonia, and the precipitated veratrine is slightly washed with cold water to free it from adhering impurities. If much water be employed in the washing, a considerable portion of the veratrine will be lost, in consequence of impure veratrine being in some degree soluble in water. The remaining steps of the British process consist in the purification of the veratrine by forming a hydrochloride in solution, decolorizing this by animal charcoal and again precipitating by ammonia.²

The U. S. process of 1870 is essentially that of Couërbe. The veratrine obtained by it, though not pure, is sufficiently so for medicinal use. A drachm of it, in this state, may be procured from a pound of *cevadilla*. Meissner, in 1819, applied the term *sabadilline* to an alkaloid extracted by him. Pelletier and Caventou had probably produced the same preparation when they announced the discovery of veratrine in the same year. This substance is the veratrine described as prepared by Couërbe's process. Couërbe, in 1834, announced the discovery of an additional alkaloid, to which he gave Meissner's old name of *sabadilline*, and Weigelin, in 1871, announced the discovery of a third alkaloid, which he called *sabatrine*. G. Merck, in 1855, obtained veratrine in a crystallized state by solution and separation from strong alcohol.

Wright and Luff (*J. Chem. S.*, 33, p. 338) have brought order from this confusion by a careful study of the whole subject. They

¹ *Veratria*, U. S. 1870.—"Take of *Cevadilla*, in moderately fine powder, *twenty-four troy ounces*; Alcohol, Sulphuric Acid, Magnesia, Water of Ammonia, Purified Animal Charcoal, Water, each, a *sufficient quantity*. Digest the *Cevadilla* with eight pints of Alcohol, for four hours, in a distillatory apparatus, with a heat approaching to boiling, and pour off the liquid. To the residue add eight pints more of Alcohol mixed with the portion distilled, and, having digested for an hour, pour off the liquid as before. Digest for a third time with the same quantity of Alcohol, together with the portion last distilled, and again pour off. Press the remains of the *Cevadilla*, mix and strain the liquids, and, by means of a water-bath, distil off the Alcohol. Boil the residue three or four times in Water acidulated with Sulphuric Acid, mix and strain the liquids, and evaporate to the consistence of syrup. Add Magnesia in slight excess, shake the mixture frequently, then express, and wash what remains. Repeat the expression and washing two or three times, and, having dried the residue, digest it with a gentle heat several times in Alcohol, and strain after each digestion. Distil off the Alcohol from the mixed liquids, boil the residue for fifteen minutes in water mixed with a little Sulphuric Acid and Purified Animal Charcoal, and strain. Having thoroughly washed what remains, mix the washings with the strained liquid, evaporate with a moderate heat to the consistence of thin syrup, and drop in sufficient Water of Ammonia to precipitate the *Veratria*. Lastly, wash the alkaloid with Water, and dry it with a gentle heat." U. S. 1870.

² James Beaton, manufacturing chemist of the U. S. Naval Laboratory at New York, recommended the following method of preparing veratrine as less complicated than the U. S. P. 1870 process, and quite satisfactory in its results. Take 73 pounds (*avoirdupois*) of *cevadilla*, rub it upon a coarse wire sieve so as to separate the seeds from the capsules, and reduce the former to a coarse powder by a Swift's drug mill. Pass the capsules also through the mill, separate the finer portion, and mix it with the ground seeds. Moisten the mixture with alcohol, and allow it to stand 12 hours; then introduce it into a displacement apparatus, and pour upon it 30 gallons of alcohol. When a convenient quantity of the liquid has passed, submit it to distillation, and return the distilled alcohol to the displacement apparatus, and proceed in the same way until the *cevadilla* is thoroughly exhausted. Collect all the alcoholic liquor from the exhausted seeds, and continue the distillation until the tincture has a syrupy consistence. Pour this while hot into eight times its volume of cold water, throw the whole on a calico filter, and wash until the washings cease to indicate the presence of the veratrine. Mix the washings with what first passed through the filter, and add ammonia water in excess (about 4 pounds). Wash the precipitated veratrine with cold water, and dry it with a very gentle heat. Beaton obtained by this process eleven and a quarter ounces of veratrine but faintly tinged with coloring matter. (*A. J. P.*, xxvi. 5.)

found three alkaloids in *sabadilla* seeds: *cevadine*, $C_{32}H_{49}NO_9$ (the alkaloid hitherto known as the veratrine of Merck); *veratrine*, $C_{37}H_{53}NO_{11}$; and *cevadilline*, $C_{34}H_{53}NO_8$. Of these, the *cevadine* (formerly *veratrine*) forms, when crystallized from alcohol, needles or compact crystals which fuse at $205^{\circ} C.$ ($401^{\circ} F.$), effloresce rapidly in the air, and become opaque, are insoluble in water, easily soluble in alcohol and ether, and dissolve in warm concentrated hydrochloric acid with a dark violet color, which on boiling becomes intensely red. When heated with alcoholic potassium hydroxide they are decomposed into *methyl-crotonic* (*tiglic*) acid and *cevine*, $C_{27}H_{43}NO_8$. The veratrine of Wright and Luff is obtained from the mother liquor of the *cevadine* by extraction with ether. It forms an uncrystallizable resinous mass, fusing at $180^{\circ} C.$, but yields crystallized salts. Boiled with sodium hydroxide it is decomposed into *dimethyl-protocatechuic* (*veratric*) acid and *verine*, $C_{25}H_{45}NO_8$. *Cevadilline* remains after the extraction of the veratrine, insoluble in ether. It is also uncrystallizable, nearly insoluble in ether and in boiling benzene, but easily soluble in fusel oil.

Flückiger recognized only two of these alkaloids, and made them both of the composition $C_{32}H_{49}NO_9$. The first, which he called *cevadine*, he stated is decomposed by boiling with barium hydroxide when in alcoholic solution, and yielded products as follows:

$C_{32}H_{49}NO_9 + 2H_2O = C_6H_5O_2 + C_{27}H_{45}NO_8$
The first of these products is *methyl-crotonic acid*, and the second is *cevine*. The other alkaloid he called *veratridine*, and gave its decomposition as follows:

The first of these products is *dimethyl protocatechuic acid*, and the second he called *veratrin*. (Flückiger, *Pharm. Chem.*, 1888, ii. p. 532.) Merck still terms the *cevadine* of Wright and Luff *veratrine*, and prepares it in white crystals of the formula $C_{32}H_{49}NO_9$, fusing at $202^{\circ} C.$ Frankforter (*A. J. P.*, 1897, 372) confirmed this formula, $C_{32}H_{49}NO_9.H_2O$, but gave to the purified veratrine the melting point from 146° to $148^{\circ} C.$

Two acids have also been found in *sabadilla*,—the *sabadillic* or *cevadic acid* of Pelletier and Caventou, forming needle-like crystals fusing at $20^{\circ} C.$, and the *veratric acid* of Merck, which Koerner showed to be *dimethyl-protocatechuic acid*.

Properties.—Veratrine is officially described as "a white, or grayish-white, amorphous powder, odorless, but causing intense irritation and sneezing when even a minute quantity reaches the nasal mucous membrane; having an acrid taste, and leaving a sensation of tingling and numbness on the tongue. It should be tasted with great caution. Slightly hygroscopic in moist air. Soluble in 1750 parts of water, 2.2 parts of alcohol, 3 parts of ether, and in 1 part of chloroform at $25^{\circ} C.$ ($77^{\circ} F.$); soluble

in 1300 parts of water at $80^{\circ} C.$ ($176^{\circ} F.$); very soluble in benzene and amyl alcohol; insoluble in petroleum benzin. When heated to $145^{\circ} C.$ ($293^{\circ} F.$), it softens, and melts at $152^{\circ} C.$ ($305.6^{\circ} F.$). Upon ignition it is consumed, leaving no residue. Its alcoholic solutions are alkaline to red litmus paper. On triturating Veratrine with sulphuric acid, in a glass mortar, the yellow or orange-red solution exhibits, by reflected light, a greenish fluorescence, which becomes more intense upon the addition of an equal volume of acid. Upon standing, the solution gradually assumes a deep red color. Sulphuric acid when heated with Veratrine gives a cherry-red color. Sulphuric acid containing a trace of selenous acid produces a brownish-green color. Sulphuric acid added to a mixture of 1 part of Veratrine and 6 parts of sugar produces a green color, changing to blue, and the mixture then becomes colorless." U. S. "Pale gray, amorphous; without odor, but, even in the most minute quantity, powerfully irritating the nostrils; strongly and persistently bitter, and intensely acid; insoluble in water, soluble in 3 parts of alcohol (90 per cent.) or of chloroform, in 6 parts of ether, and in diluted acids, leaving slight traces of an insoluble brown resinous matter. It dissolves in nitric acid, yielding a yellow solution. Warmed with hydrochloric acid, it dissolves with production of a blood-red color lasting several days. Treated with fifty or sixty times its weight of sulphuric acid, the mixture turns yellow, subsequently acquires a yellowish-green fluorescence which becomes more distinct on the addition of more acid and slowly changes to bright red, or, if warmed, violet-red. Heated with access of air, Veratrine melts to a yellow liquid, and at length burns away, leaving no residue (absence of mineral impurity)." Br.

Uses.—Veratrine is locally irritant, and exercises a peculiar influence on the nervous system. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling. Sometimes an evanescent blush is produced, and still more rarely an eruption upon the skin, but, in general, no decided signs of inflammation are evinced. Upon the denuded cutis, however, veratrine and its salts are powerfully irritating; in the mouth and fauces they produce an almost insupportable sense of acrimony, and snuffed up the nostrils excite violent sneezing. Magendie states that when taken internally in the dose of a quarter of a grain they promptly produce abundant alvine evacuations, and in larger doses provoke more or less violent vomiting. Experimenters have observed similar effects.

When it is taken in toxic doses veratrine causes violent vomiting, serous purging, often with intense burning in the mouth and throat, and general muscular weakness. No fatal case of poisoning is on record; but in the experiments of Esche on himself a half-grain of the acetate produced collapse, with a pale, cold,

wet skin, pinched features, a rapid, thready, irregular pulse, violent vomiting, and marked muscular tremblings. The phenomena of veratrine poisoning in dogs, rabbits, etc., are failure of muscular power, along with violent muscular twitchings and convulsions, which are often plainly excited by external irritants, severe vomiting, generally but not always accompanied by purging, and disturbance of motion, respiration, and circulation. The pulse is at first, if the dose be not too large, quickened and strengthened, but in a very short time it becomes slower and weaker, and finally very frequent, thready, and irregular. When very large doses are given, the animal often dies at once of a universal paralysis. Veratrine is a powerful muscle poison, producing a primary stage of muscular hyperexcitability and a condition in which momentary stimuli produce tetanic spasms, and a final stage of rigidity and complete loss of contractility. It is paralyzant to the motor nerves, and probably also to the sensory nerves. Upon the cerebral centres it has little action; its exact influence upon the spinal cord has not been determined. It is a powerful depressant to the respiratory centre, and acts upon the heart muscle as upon the voluntary muscles. In the earlier stages of its action it slows the pulse and increases the blood pressure by stimulating the inhibitory cardiac nerves, and probably also by stimulating the muscle fibres in the heart itself and in the walls of the arterioles.

Veratrine has been chiefly employed in *gout*, *rheumatism*, and *neuralgia*, and has also been praised in *epilepsy* and various other nervous diseases. Its remedial value is very doubtful, and in this country it is very rarely administered. One-thirtieth of a grain (0.002 Gm.) may be given in the form of pill, and repeated every three or four hours till the effects of the medicine are experienced. Some prefer the salts for internal use. Any one of these salts may be prepared by treating veratrine with water acidulated with the acid to perfect neutralization, and then carefully evaporating to dryness. It is employed to some extent as an alterative counter-irritant, locally applied in *chronic swellings*, *stiffening*, and *induration of the joints*, whether from *rheumatism*, from *scrofula*, or simply from *local injuries*, as *sprains*.

Veratrine may be used either dissolved in alcohol, or rubbed up with lard or other unctuous substance in the proportion of from five to twenty grains to the ounce. It is advisable that the alkaloid should be dissolved in a little alcohol or oleic acid before being mixed with the lard. Of the ointment thus prepared, a portion of the size of a filbert may be rubbed upon the skin over the part affected, night and morning, from five to fifteen minutes, or until the more urgent symptoms are relieved. Veratrine may be used in this way to the amount of from two to four grains in the day. Care must be taken to see that the cuticle to which

the ointment is applied is sound. When the skin is irritable, smaller quantities than those above mentioned must be used.

Dose, one-thirtieth of a grain (0.002 Gm.).

Off. Prep.—Oleatum Veratrinæ, U. S.; Unguentum Veratrinæ, U. S., Br.

VERATRUM. U. S.

VERATRUM [Veratrum Viride, Pharm. 1890]

(və-rā'trŭm)

"The dried rhizome and roots of *Veratrum viride* Aiton (American Hellebore) or *Veratrum album* Linné (White Hellebore) (Fam. *Liliacæ*)." U. S.¹

V. viride: Green Hellebore, American Hellebore, Big or False Hellebore, Swamp Hellebore, Indian Poke, Itch-weed, Tickle-weed, Bugbane; *Vératré vert*, Fr.; Grüner Germer, G.; Vedegambre verde, Sp.

V. album: White Hellebore, White Veratrum, Ling-wort, Sneezewort, Neezewort; Hellebore blanc, Fr. *Od.*; *Vératré blanc*, Fr.; Rhizoma Veratri, P. G.; Weisses Nieswurz, Weisses Germer, G.; Vedegambre blanco, Sp.

Veratrum viride, Aiton, *Hort. Kew.* (1789) 422; Willd., *Sp. Plant.* iv. 896; Bigelow, *Am. Med. Bot.*, ii. 121; B. & T. 286. *V. album*, Michaux, not *V. album*, Sereno Watson, which is *V. californicum*, Durand.—The American hellebore, known also by the names of *Indian poke*, *poke root*, and *swamp hellebore*, has a perennial, thick, fleshy rhizome, the upper portion of which is tunicated, the lower solid, and beset with numerous whitish roots. The stem is annual, round, striated, pubescent, and solid, from three to six feet in height, furnished with bright green leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent, and embrace the stem at their base, thus affording it a sheath for a considerable portion of its length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong-lanceolate. The panicle consists of numerous flowers, distributed in racemes with downy peduncles. Each flower is accompanied by a downy, pointed bract, much longer than its pedicel. The perianth consists of six oval acute segments, thickened on the inside at their base, with the three alternate segments longer

¹ The revisers of the U. S. P. (8th Rev.) seem to us to have made an error in recognizing the two veratrum rhizomes as one drug. That the two species are very closely allied, and the two rhizomes histologically, chemically, and toxicologically very similar is indisputable, but similarity is not identity. The European plant seems to be more actively poisonous than is the American, and has been said by some chemists to contain a larger proportion of the alkaloids. It usually also has a distinctly greater action upon the intestinal tract and it is probable that the proportionate amounts of the alkaloids differ in the two species. The conclusions reached in an elaborate physiological research made by H. C. Wood and H. C. Wood, Jr., for the Committee of Revision was that the drugs can scarcely be distinguished physiologically but that the European plant is more likely to disturb the intestines and that in the absence of any cogent reason for recognizing *V. album*, *Veratrum viride* should alone be retained.

than the others. The six stamens have recurved filaments and roundish two-lobed anthers. The ovary is ovoid, tri-carpellary; styles three and persistent. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those below fruitful. The fruit is a three-lobed capsule, three-celled, and containing flat imbricated seeds. This indigenous species of veratrum inhabits swamps, wet meadows, and the banks of mountain streamlets. It is more abundant northward, but reaches as far south as Georgia. From May to July is the season for flowering. It is doubtful whether the root should be collected in autumn or just before flowering. It should not be kept longer than one year, as it deteriorates by time.

Veratrum album, L. *V. viride*, Roehl., but not *V. viride*, Aiton.—The specific difference between this plant, which is a native of Europe and Northern Asia, and *V. viride* of North America has been questioned by various botanists, but it is now generally acknowledged that the two species are distinct. (See *Index Kewensis*; also Engler and Prantl.) *V. album* resembles closely the American species, but is distinguished by its yellowish-white flowers. The rhizome of *V. nigrum* of Central Europe is said to be sometimes substituted for that of *V. album*, but is much smaller. According to the Pharmacographia, that of the Mexican species, *V. frigidum*, Schl., exactly resembles that of *V. album*.

Properties.—As found in commerce, veratrum is usually in small pieces or fragments, but sometimes it comes whole or sliced, so that its characteristic form may be observed. In this condition it is seen to consist of a rhizome one to three inches in length by somewhat less than an inch in thickness where broadest, tapering to a very obtuse or truncated extremity, simple or divided, compact but light, of a dark-brown color externally, and either closely invested with numerous yellow rootlets often several inches long, or exhibiting marks on the surface whence they have been removed. When sliced, the cut surface is of a dingy-white color. The rootlets are from three to six inches long, about as thick as a large knitting needle, or somewhat thicker, obviously much shrunk in drying, and marked by numerous closely set indentations, which give them a characteristic appearance. Not unfrequently portions of the dried stem or leaf-stalks remain attached to the rhizome, which should always be rejected, as they were ascertained by Procter to be inert. (*A. J. P.*, 1864, p. 99.)

Veratrum is officially described as follows: "Rhizome upright, ovoid or obconical, 2.5 to 7 Cm. long and 2 to 5 Cm. thick, externally light to dark brown or blackish, frequently bearing at the summit some coarsely fibrous remains of leaf bases; internally grayish- or yellowish-white, showing numerous short irregular wood-bundles. Roots emanating from all sides of the rhizome, numerous, shrivelled, whitish or

light yellowish-brown, from 10 to 20 Cm. long, and 1 to 2 Mm. thick. Inodorous, but strongly sternutatory when powdered; taste bitterish and very acrid." *U. S.* The Committee of Revision of the *U. S. Pharm.* (8th Rev.) do not distinguish between the rhizomes of the two species of veratrum. It has been asserted that the color of *V. album* is much lighter than that of *V. viride*, but this certainly is practically incorrect, however it may apply to carefully preserved specimens. Very commonly the roots have been removed from commercial *V. album*, while in America they are generally allowed to remain on the rhizomes. According to R. H. Denniston, no microscopic differences can be detected in the rhizomes, but in the roots distinction is possible owing to the fact that directly beneath the epidermis in the *V. viride* the collenchyma region consists of but two or three veins of large, irregular and distorted cells, while in *V. album* this region is generally made up of seven to eight rounded, thicker-walled and smaller cells, which are not in the least distorted. Any such test is, of course, inapplicable to the drug in powder. In the color test proposed by R. H. Denniston, sulphuric acid is added to the powder; with *V. album* a brick-red color, with *V. viride* an orange-red color, will be produced. Of course the test is of little value in determining the character of a powder, as it does not possess sufficient differentiation.

Pelletier and Caventou, in 1819, found in the rhizome of *Veratrum album* a substance which they regarded as identical with the veratrine just announced by Meissner as contained in *sabadilla* seeds. Simon (*Ann. Ch. Ph.*, 24, p. 214), in 1837, found the alkaloid *jervine* also in *Veratrum album*. Worthington (*A. J. P.*, 1839, p. 89) found an alkaloid in *Veratrum viride* which he considered to be the veratrine then known from other sources. Richardson, in 1857, and Percy, in 1864, confirmed his results. Bullock (*A. J. P.*, 1865, p. 321) shortly after, found on examination of *Veratrum viride*, that while it contained at least two characteristic alkaloids, neither of these was veratrine. The alkaloids noted by Bullock were named in a former edition of this work *viridine* and *veratroidine*. Peugnet (*N. Y. M. R.*, 1872, p. 120), in 1872, showed the identity of the first of these with *jervine*, and this was confirmed by Mitchell (*A. J. P.*, 1874), who also made out a distinct alkaloid in *Veratrum album*, to which he applied the name of *veratrubine*. The veratroidine discovered by Bullock in *Veratrum viride* in 1865 was also found in *Veratrum album* by Tobien in 1877. In a paper published in the *A. J. P.*, April, 1876, Bullock expressed his doubt as to the existence of veratroidine as a distinct alkaloid, considering that it might have been only *jervine* admixed with resin. Here the matter rested until the elaborate researches of Wright and Luff (*J. Chem. S.*, 35, pp. 405, 421), who found in *Veratrum album*, *jervine*, $C_{26}H_{43}NO_2 + 2H_2O$, *rubijer-*

vine, $C_{26}H_{43}NO_2$, *pseudojervine*, $C_{26}H_{43}NO_7$, and *veratralbine*, $C_{26}H_{43}NO_5$ (?), and also traces of an alkaloid having sternutatory power (possibly *cevadine*). In *Veratrum viride* they found jervine, pseudojervine, cevadine, very little rubijervine, and traces of veratrine and veratralbine. Of these, rubijervine probably agrees with Bullock's veratroidine, although as prepared by Bullock in his earlier experiments it was undoubtedly mixed with resin, as the fusing point given (270° to 275° F.) is much lower than that given by Wright and Luff for their pure crystals, which fused at 236° C. (456.8° F.). Pseudojervine forms crystals very similar to those of jervine, but it fuses at 299° C. (570.2° F.), instead of 231° to 237° C. (447.8° to 458.6° F.). Pehkschen (A. J. P., 1891) finds jervine in both the *Veratrum* species. Obtained by recrystallization from absolute alcohol it forms snow-white crystals of the formula $C_{14}H_{22}NO_2$ (determined by the analysis of the base and of its hydrochloride and sulphate). It melts at 237.7° C., and is slightly levogyre. He finds veratroidine (rubijervine of Wright and Luff), and gives it the formula $C_{22}H_{33}NO_3$ (determined both by analysis and by molecular weight determination). It melts at 149.2° C., and is optically inactive. He obtained, thirdly, an alkaloid in rhombic crystals, which is probably a purer form of Wright and Luff's *pseudojervine*. Its formula is $C_{26}H_{43}NO_{12}$. It melts at 259.1° C., and is optically inactive. No color reactions could be obtained with this base, but if the slightest quantity of veratroidine or jervine is added, color reactions agreeing with Wright and Luff's pseudojervine are obtained. A very small quantity of a fourth alkaloid (Wright and Luff's veratralbine) was obtained, but not enough to allow of present investigation. Salzberger (A. J. P., 1891) obtained the three bases jervine, rubijervine, and pseudojervine, and two new ones *protoveratrine*¹ and *protoveratridine*, from the rhizome of *Veratrum album*; the first of these two bases has the formula $C_{32}H_{51}NO_{11}$, and crystallizes in microscopic four-sided plates, which melt with charring at 245° to 250° C. The base is exceedingly poisonous and violently sternutatory. It is insoluble in water, benzene, and petroleum benzin, slightly soluble in chloroform, boiling 96 per cent. alcohol, and ether. Dilute acids, with the exception of acetic acid, dissolve it. *Protoveratridine*, $C_{26}H_{45}NO_5$, occurs as colorless four-sided plates, which melt at 265° C. It is not poisonous, and does not cause sneezing. It is almost insoluble in the common solvents, but is soluble in dilute acids. Worthington pointed out the presence of gallic acid and sugar in *Veratrum viride*.

¹ According to the experiments of Watts Eden (A. E. P. P., xlix.), protoveratrine is in mammals twenty times more poisonous than crystallized veratrine, paralyzing the vagus, affecting the muscles, at first increasing but soon markedly depressing their excitability and power, and causing death by a centric disturbance of respiration. The alkaloid also affects the heart, and is a powerful local anæsthetic.

Uses.—When taken in small doses by man, veratrum first reduces the force without much lessening the frequency of the pulse, but after a time the pulse rate falls very much. If any exertion be made during this stage of depression, the slow pulse will be suddenly converted into an exceedingly rapid one. The slow pulse is sometimes moderately full, but is always very soft and compressible; the rapid pulse is exceedingly feeble and small, often thready, and may become imperceptible. Severe nausea and vomiting accompany or follow the reduction of the pulse rate. That the latter is not due to gastric disturbance is, however, shown by the fact that it often precedes the stomachic symptoms, and may exist without them. During the stage of depression there is always a decided muscular weakness and relaxation. After a poisonous dose the symptoms above noted are increased in intensity and become very alarming. A running, almost imperceptible pulse, a cold, clammy skin, intense nausea and incessant attempts at vomiting, or retching, or hiccough, absolute muscular prostration, faintness, vertigo, loss of vision, and semi-unconsciousness, make up the group of extreme symptoms. For full details as to the method in which these symptoms are produced, the reader is referred to H. C. Wood's *Treatise on Therapeutics*; the allotted space here will allow us only to state that veratrum viride is a powerful spinal and arterial depressant, exerting little or no direct influence upon the cerebral centres; it lowers the pulse rate by a direct action on the muscle (jervine) and by stimulating the inhibitory nerves (rubijervine); it diminishes the force of the heart beat by a direct influence on the cardiac muscle (jervine), and produces a general vasomotor paralysis (jervine) more or less complete according to the size of the dose. By the action especially of the jervine the spinal motor centres are directly depressed. Neither the sensory centres nor the motor or sensory nerves are distinctly affected. *Veratrum viride* is used in practical medicine to reduce arterial excitement and to quiet spinal spasms. In *adynamic fevers* it should never be administered, but in the first stage of *frank pneumonia*, or in any disease when true sthenic arterial excitement is to be combated, except it be in *gastritis* or *peritonitis*, it may be employed as a prompt, efficient, and very safe remedy,—very safe, since it is almost incapable of producing death in the robust adult unless used with great recklessness and in repeated doses. In *chronic cardiac diseases* it may be employed in precisely those cases in which digitalis is contra-indicated—i.e., where there is excessive hypertrophy.

In poisoning, vomiting should be encouraged by large draughts of warm water until the stomach is well washed out. Then the patient should be forced to lie flat upon the back, with the head lower than the feet, and the efforts at vomiting should be restrained. If they cannot be checked, and if the prostration be severe,

on no account should the patient be allowed to rise up, but must be made to vomit into a towel. A full dose of tincture of opium should be given by the rectum, and brandy or whisky administered by the mouth. These will sometimes be retained only when given undiluted, and in such form they will often quiet the stomach at once. If the stomach refuse alcohol in any shape, the rectum should be utilized. Ammonia may be employed as an adjuvant to alcohol, and in extreme cases should be injected hypodermically, or even into a vein. Strychnine and digitalis should in all severe cases be used hypodermically. The use of external heat is important, and mild flagellations, rubbing with coarse towels, sinapisms, etc., may be used to keep up the external capillary circulation. The drug should always be administered in the form of the *fluidextract*, dose, one to three minims (0.05 to 0.15 Cc.); or of the *tincture* (U. S. P., 8th Rev.), dose, fifteen minims (1 Cc.), to be given every hour or two, and closely watched. The occurrence of nausea should be the signal for the suspension of the remedy.

Whenever a full physiological effect of the drug is desired, the practitioner should order, and if possible obtain, *Veratrum viride*, not *veratrum*, and thereby avoid probability of untoward effects and also personal responsibility.

Dose, two grains (0.13 Gm.).

Off. Prep.—Fluidextractum Veratri, U. S.; Tinctura Veratri, U. S.

VIBURNUM OPULUS. U. S.

VIBURNUM OPULUS [Cramp-bark]

(vī-bŭr'nŭm ɔp'ŭ-lŭs)

"The dried bark of *Viburnum Opulus* Linné (Fam. *Caprifoliaceæ*)."
U. S.

Wild Guelder-rose, Cherry-wood, Red or Rose Elder, Pinchusion Tree, Squaw Bush; in cultivation Snow-ball Bush; Obier, Fr.; Wasserholderrinde, Wasser-schwelke, G.

Besides the official species of this genus, the *V. obovatum*, Walt., a tree shrub growing from Virginia southward, which is botanically very closely allied to *V. prunifolium*, is said to be an antiperiodic. (A. J. P., 1878.) *V. lantana*, L., (*V. trilobum*, Marsh.), a European species, probably shares the therapeutic properties of the official species. *Viburnum Opulus*, *cranberry-tree* or *high bush cranberry*, belongs to the section of the genus which has peduncled cymes, light red, acid, roundish drupes, with very flat orbicular not sulcate stones, palmately veined leaves, and scaly winter buds. It is a large bush, reaching the height of ten feet, growing in low grounds from New Brunswick far westward, and southward to Pennsylvania. The leaves are from three- to five-ribbed, strongly three-lobed, broadly wedge-shaped or truncate at the base, with the spreading pointed lobes mostly toothed in the sides and entire in

the sinuses. The petioles bear two glands at the apex. The *snow-ball tree*, or *Guelder rose*, is a variety in which the whole inflorescence has been turned into a mass of showy sterile flowers.

Properties.—The bark is officially described as "in somewhat transversely curved pieces, occasionally in quills, of variable length, and 0.5 to 2 Mm. thick; outer surface grayish-brown, longitudinally wrinkled, with large brown lenticels and brownish-black fruit-heads of a lichen; inner surface light brown, longitudinally striate; fracture uneven, fibrous; transverse sections showing several bands of bast fibres; odor slight; taste somewhat astringent and bitter." U. S. For studies of *Viburnum* barks, see A. J. P., 1895, 387, 394; also *Ph. Post*, 35, 773. Gibson (*Proc. Indiana Pharm. Assoc.*, 1900, 112) believes that there is a glucoside present in the bark of *V. Opulus*; he describes it as resinous, greenish in color, soluble in alcohol, slightly soluble in water.

Uses.—This bark has been so little employed in medicine that we are at a loss to understand the reason of its introduction into the Pharmacopœia. Its berries are used domestically to a considerable extent as a substitute for the ordinary cranberry, and are antiscorbutic. It may be that the bark shares the medicinal properties of *V. prunifolium*, but this has not been demonstrated.

Dose, thirty to sixty grains (2.0 to 3.9 Gm.).

Off. Prep.—Fluidextractum Viburni Opuli, U. S.

VIBURNUM PRUNIFOLIUM. U. S.

(Br. Add.)

VIBURNUM PRUNIFOLIUM [Black Haw]

(vī-bŭr'nŭm prŭ-nŭ-fŏ-lŭ-ŭm)

"The dried bark of the root of *Viburnum prunifolium* Linné, or of *Viburnum Lentago* Linné (Fam. *Caprifoliaceæ*)."
U. S.

Viburnum, Br. Add.; also U. S. 1880; Stagbush, Sheep-berry.

Viburnum prunifolium, L.—A tall, very handsome shrub, which is quite common in the Middle and Southern United States, east of the Mississippi, flowering in May and ripening in the early autumn its ovoid or oblong blackish fruit. It is specifically characterized by its acuminate, glabrous winter buds, by its acuminate, sharply serrulate, ovate leaves on long, slender, sometimes broadened and wavy margined petioles. Its sessile cymes are 2 to 5 inches broad and bear oval bluish-black drupes.

Viburnum Lentago, L., *Sheep Berry*, *Sweet Viburnum*, resembles the previous species, but has the winter buds smaller, less acute and often reddish pubescent, and its leaves stouter petioled and not acuminate at the apex. Its geographical limit overlaps that of *V. prunifolium*, but extends much further westward

and northward, even to Manitoba. The bark of *V. dentatum*, L., or *Arrow wood*, is said to be sometimes substituted for the official drug.

Properties.—The bark is officially described as “in irregular or quilled pieces, rarely exceeding 4 Mm. thick; externally dingy brown, shallowly fissured and slightly scaly; inner surface rust-brown; fracture weak, short, and uneven, the inner layer whitish, the middle rust-brown, the outer dark brown; groups of stone cells readily distinguishable in transverse section; odor slight, peculiar; taste very bitter, somewhat astringent.” *U. S.* (For microscopic characters of bark see *P. J.*, 70, p. 197.) Herman van Allen found the following constituents in viburnum: 1, a brown resinous body, of a very bitter taste, from which it was found impossible to separate the sugar; 2, a greenish-yellow resin or neutral principle of a bitter taste, slightly soluble in water, freely so in alcohol, called by Krämer *viburnin*; 3, valeric acid; 4, a tannic acid giving a greenish-black color with ferric salts; 5, oxalic acid; 6, citric acid; 7, malic acid; 8, sulphates; 9, calcium, magnesium, potassium, and iron chlorides. (*A. J. P.*, 1880, 443.) As the result of elaborate investigation, T. Shennan (*Royal Coll. Phys. Lab. Rep.*, Edinburgh, vi. 1897) concludes that the *Viburnum prunifolium* contains *viburnic*—i.e., valeric—acid, and a non-volatile alkaloid which, however, he failed to obtain in a pure condition.

Uses.—D. L. Phares, who first called the attention of the profession to this drug, affirms that it is nervine, antispasmodic, astringent, diuretic, and tonic, and is especially useful in the nervous diseases of pregnancy and in the prevention of miscarriage. R. L. Payne, Jr., has found that when given in toxic amount to the lower animals viburnum produces muscular weakness, ending in complete paralysis with loss of reflex action, which he believes to be due to an influence upon the motor side of the spinal cord. In warm blooded animals there is also marked lowering of the arterial pressure, believed by Payne to be the result of a direct action of the drug upon the heart. The experiments of Payne have in a measure been confirmed by those of T. Shennan, who finds that large amounts of the drug injected directly into the veins of a warm blooded animal lower blood pressure, while in the frog the extract produces distinct depression of the voluntary muscles and also of the heart. As Shennan took six drachms of the fluidextract within thirty minutes, with no demonstrable effect except a doubtful decrease of the rate and force of the pulse, it is plain that the drug is very feeble. It has, however, come into some vogue as a remedy in the treatment of *dysmenorrhœa*, after-pains, and ovarian irritation; it has also received especial commendation in those cases in which there is a persistent disposition to miscarriage. In menorrhagia it may be given in full doses several days before the coming on and during the continuance of

the menstrual hemorrhage. The solid extract (*dose*, from three to ten grains) does not represent the drug completely, owing to loss of volatile acid; so that the fluidextract should be preferred, in doses of from one-half to one fluidrachm (1.8 to 3.75 Gm.).

Dose, thirty to sixty grains (2.0 to 3.9 Gm.).

Off. Prep.—Fluidextractum Viburni Prunifolii, *U. S.*

VINA MEDICATA.

MEDICATED WINES

(vīnā mēd-i-cā'tā)

Vins médicaux, *Ænolés*, *Fr.*; Medicinische Weine, *G.*

The advantages of wine as a pharmaceutical menstruum are that, in consequence of the alcohol it contains, it dissolves substances insoluble in water, and, to a certain extent, resists their tendency to spontaneous change, while at the same time it is less stimulating than strong or diluted alcohol, owing to its smaller proportion of alcohol. The acid which it usually contains serves in some instances to increase its solvent power. But most wines, particularly the light varieties, are liable to undergo decomposition, and even the strongest acquire such a liability from the principles which they extract from vegetable substances; so that medicated wines, though they keep much better than infusions or decoctions, are inferior in this respect to the tinctures. The proportion of alcohol, moreover, is not constant, and the preparations, therefore, made with them were formerly of unequal strength. From these causes, few medicated wines are at present retained. In the choice of wine, the purest and most generous should be selected. The medicated wines, in consequence of their liability to change, should be prepared in small quantities, from wine of proper strength, and should be kept in a cool place. *Detannated wine* may be made by carefully adding tincture of ferric chloride to the wine, a little at a time, until a further addition does not produce a dark color, then pouring about 6 fl. oz. of fresh milk into each gallon of the wine, shaking the mixture well, allowing to stand a little while and filtering (*M. R.*, 1904, 40).

In the *U. S. P.* (8th Rev.) one medicated wine was admitted—*Vinum Cocæ*, and one was dismissed—*Vinum Colchici Radicis*.

VINUM ALBUM. *U. S.* (Br.)

WHITE WINE

(vī'nūm āl'būm)

Vinum Xericum, *Br.*; Spanish wine; *Vinum Generosum Album*; *Vin blanc*, *Fr.*; *Weisswein*, *G.*; *Vino blanco*, *Sp.*

“An alcoholic liquid, made by fermenting the juice of fresh grapes, the fruit of *Vitis vinifera*—

era Linné (Fam. *Vitaceæ*), freed from seeds, stems, and skins, and subjected to the usual cellar-treatment for fining and aging. When White Wine is prescribed without further specification, it is recommended that a dry White Wine of domestic production be employed. White Wine should be preserved in well-closed casks filled as full as possible, or in well-stoppered bottles, in a cool place." *U. S.* "A Spanish wine." *Br.* (See *Vinum Rubrum*, page 1339.)

VINUM ANTIMONII. U. S. (Br.)

WINE OF ANTIMONY

(vī'nūm ān-tī-mō'nī-i)

Vinum Antimoniale, Br.; Antimonial Wine; *Vin antimoniale, Vin émétique, Vin stibé, Fr.; Vinum Stibiatum, P. G.; Brechwein, G.; Vino emético, Sp.*

* "Antimony and Potassium Tartrate, four grammes [or 62 grains]; Boiling Distilled Water, sixty-five cubic centimeters [or 2 fluidounces, 95 minims]; Alcohol, one hundred and seventy-five cubic centimeters [or 5 fluidounces, 440 minims]; White Wine, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Antimony and Potassium Tartrate in the Boiling Distilled Water. Add this solution to a mixture of the Alcohol with seven hundred and twenty-five cubic centimeters [or 24 fluidounces, 247 minims] of White Wine; mix well, and allow the mixture to stand until it has cooled. Then filter and add sufficient White Wine through the filter to make the liquid measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Tartarated Antimony, 40 grains or 4 grammes; Distilled Water, boiling, 1 fl. ounce (Imperial measure) or 44 cubic centimeters; Sherry, a sufficient quantity. Dissolve the Tartarated Antimony in the Distilled Water; mix the solution with sufficient Sherry to form one pint (Imp. meas.) or eight hundred and seventy-five cubic centimetres of Antimonial Wine." *Br.*

The *Br. Ph.* 1898 formula contains 2 grains of tartar emetic in the fluidounce, the *U. S.* preparation (8th Rev.) directs less of the antimonial salt, as it contains about 1.8 grains in a fluidounce.

Considerable difficulty is often experienced in effecting a solution of tartar emetic in wine, and precipitation is likely to occur after the solution has been effected. These results are attributable either to impurity in the antimonial salt, which frequently contains potassium bitartrate and various insoluble substances, or to inferiority in the character of the wine, which holds in solution vegetable principles that form insoluble compounds with the antimony. Paris stated that he had seen the decomposition of the tartar emetic so complete that no traces of the salt could be detected in the supernatant liquid. The difficulty is not avoided by the plan adopted in the *U. S. Pharmacopœia* of

first dissolving the antimonial in water and then adding the wine; for, even allowing that the solution may be accomplished, the same ingredients are present, and their mutual reaction must ultimately result in the same effects. The proper course is to select perfectly pure crystallized tartar emetic, and sound wine, which make a permanent solution. To obviate the risk of decomposition, the Dublin College directed water and rectified spirit in about the proportion in which these exist in the wines just mentioned. The only objection to this menstruum is the want of color, which renders the preparation liable to be confounded with less active liquids.

The advantages of antimonial wine are that it affords the means of administering minute doses of tartar emetic, and that it is more permanent than an aqueous solution of that salt, which is liable to spontaneous decomposition. It is usually administered in small doses as a diaphoretic or an expectorant, or as an emetic in infantile cases. When a considerable quantity of tartar emetic is requisite, it should always be given in extemporaneous aqueous solution.

Dose, as an expectorant or a diaphoretic, from ten to thirty minims (0.6 to 1.8 Cc.), given frequently; as an emetic for children, from thirty minims to a fluidrachm (1.8 to 3.75 Cc.), repeated every fifteen minutes till it operates.

Off. Prep.—Mistura Glycyrrhizæ Composita, *U. S.*

VINUM AURANTII. Br.

ORANGE WINE

(vī'nūm āu-rān'tī-i)

Vin de Ecorce d'orange amère, Fr.; Pomeranzenwein, G.

"Wine made by the fermentation of a saccharine solution to which Fresh Bitter-Orange Peel has been added." *Br.*

This is officially described as "a vinous liquid, having a golden sherry color, and a taste and aroma derived from the Bitter-Orange Peel. It contains 10 to 12 per cent. by volume of ethyl hydroxide. It is but slightly acid to litmus-paper. When a mixture of 50 cubic centimetres of this Wine and 50 cubic centimetres of water, acidulated with 5 cubic centimetres of the volumetric solution of sulphuric acid, is distilled, the distillate, after the rejection of the first 10 cubic centimetres, shaken with ether, and the ethereal liquid separated and its ether removed by evaporation, the residue should not yield a violet coloration when mixed with test-solution of ferric chloride (absence of salicylic acid). It should yield not more than the slightest reactions with the tests for sulphites." *Br.*

This wine is used as a vehicle, and when the feeble tonic action of orange peel is desired.

Off. Prep.—Vinum Ferri Citratis, *Br.*; Vinum Quinina, *Br.*

VINUM COCÆ. U. S.

WINE OF COCA

(vī'nūm cō'cæ)

Vinum Erythroxyli; Vin de Coca, *Fr. Cod.*; Cénolé de Coca, *Fr.*; Cocawein, *G.*; Vino de coca del Peru, *Sp.*

* "Fluidextract of Coca, *sixty-five cubic centimeters* [or 2 fluidounces, 95 minims]; Alcohol, *seventy-five cubic centimeters* [or 2 fluidounces, 257 minims]; Sugar, *sixty-five grammes* [or 2 ounces av., 128 grains]; Red Wine, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Sugar in *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Red Wine, add the Alcohol and Fluidextract of Coca, and enough Red Wine to make the liquid measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Set the mixture aside for two days; then filter through paper, in a well-covered funnel." *U. S.* This wine was introduced into the U. S. P. (8th Rev.) for the first time; it may be necessary to allow the liquid to stand longer than two days if subsequent filtration is to be avoided.

Uses.—This is used as a stimulating tonic in cases of *debility*, especially in the convalescence from acute fevers. It must, however, be employed with caution, as there is grave danger of the formation of a habit.

Dose, two to eight fluidrachms (7.5 to 30 Cc.).

VINUM COLCHICI. Br.

COLCHICUM WINE

(vī'nūm cōl'gĥi-cī)

Vinum Colchici Radicis; Wine of Colchicum Root; Vin de Bulbe de Colchique, *Fr. Cod.*; Cénolé de Bulbe de Colchique; Zeitsosenknollenwein, *G.*; Vino con colchico, *It.*

"Colchicum Corm, in No. 20 powder, 4 ounces (Imperial) or 200 grammes; Sherry, 1 pint (Imp. meas.) or 1000 cubic centimetres. Macerate as directed for tinctures." *Br.*

Wine of colchicum root was not admitted to the U. S. P. (8th Rev.) because of the variable quality of colchicum root as found in the market and the superiority of the seeds in uniformity (see *Vinum Colchici Seminis*); the process of the U. S. P. 1890 is appended.¹

The British 1898 colchicum wine is only half the strength of the U. S. 1890 preparation. The latter was intended to be a saturated vinous

tincture of colchicum. As the colchicum bulb imported into the United States is of variable strength, the only method by which an active preparation can be insured is to employ a large quantity of it in proportion to that of the menstruum, but with even this method there is uncertainty in the strength of the resulting wine. A wine made from the fresh bulb is occasionally imported from England, and is thought by some to be more efficacious than the official preparation, but we have seldom been disappointed in obtaining the effects of colchicum from the wine prepared according to the directions of the U. S. P. 1890. In *gout* it is frequently given in connection with magnesia and its sulphate. It is a violent poison in overdoses. Two fluidrachms and a half (9.3 Cc.) of it are said to have caused death.

Dose, ten to forty minims (0.6 to 2.5 Cc.).

VINUM COLCHICI SEMINIS. U. S.

WINE OF COLCHICUM SEED

(vī'nūm cōl'gĥi-cī sēm'i-nīs)

Vin de Semence de Colchique, *Fr.*; Vinum Colchici, *P. G.*; Zeitsosenwein, Zeitsosensamenwein, *G.*

* "Fluidextract of Colchicum Seed, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; White Wine, *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix them. Set the mixture aside for two days; then filter through paper, in a well-covered funnel." *U. S.*

As the seeds of colchicum are less liable to injury than the bulb, and are, therefore, of more uniform strength, there is not the same necessity for preparing a wine of the root. The wine of the U. S. P. (8th Rev.) is made from the assayed fluidextract and is of 10 per cent. strength instead of 15 per cent., as in the U. S. P. 1890. Williams, who introduced the seeds into use, supposed that their active properties resided in their coating, and that it was, therefore, not advisable to bruise them in preparing the wine or tincture. But this view was contradicted by the experiments of Bonnewyn, who asserted that he found a larger proportion of colchicine in a tincture of the bruised than in a tincture of the unbruised seeds. (See *A. J. P.*, xxvi. 120.) L. I. Morris has shown, however, that by *digesting* instead of *macerating* the whole seeds the colchicine can be all extracted. (See *Tinctura Colchici*.) In order that the seeds may be properly comminuted, Maisch recommended that they be macerated for two or three days in a portion of the wine, before being bruised. (*Ibid.*, xxviii. 514.) It is stated that sometimes this tincture becomes turbid from the development of the yeast fungus in it. (Vulpius, *A. J. P.*, xlv. 212.) Two fluidounces (60 Cc.) have proved fatal.

Dose, thirty minims to two fluidrachms (1.8 to 7.5 Cc.).

¹ *Vinum Colchici Radicis. U. S. 1890. Wine of Colchicum Root.*—"Colchicum Root, in No. 30 powder, four hundred grammes [or 14 ounces av., 48 grains]; Alcohol, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; White Wine, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Alcohol with *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of White Wine. Moisten the powder with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the menstruum, pack it moderately in a conical glass percolator, and gradually pour upon it, first, the remainder of the menstruum, and afterwards enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S. 1890.*

VINUM ERGOTÆ. U. S.

WINE OF ERGOT

(vī'nūm ɛr'gō-tæ)

Vin (Cenolé) de Seigle Ergoté, *Fr.*; Mutterkornwein, *G.*

* "Fluidextract of Ergot, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Alcohol, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; White Wine, *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. *Mix* them. Set the mixture aside for two days; then filter through paper, in a well-covered funnel." *U. S.*

This wine is now made from the fluidextract, and, although the proportional strength is greater than that of the *U. S. P.* 1890 (20 per cent. of fluidextract in the *U. S. P.* (8th Rev.) to 15 per cent. of ergot in the *U. S. P.* 1890), the probabilities are, that as ergot is not among the assayed drugs, the two preparations will be about equal in strength as found in commerce.

Dose, of this wine, for a woman in labor, from two to four fluidrachms (7.5 to 15 *Cc.*); for other purposes, from one to two fluidrachms (3.75 to 7.5 *Cc.*), to be repeated several times a day, and gradually increased if necessary.

VINUM FERRI. U. S. (Br.)

WINE OF IRON

[Vinum Ferri Citratis, *Pharm.* 1890, Wine of Ferric Citrate]

(vī'nūm fēr'ri)

Vinum Ferri Citratis, Vinum Chalybeatum, *Br.*; Wine of Iron Citrate; Vin Chalybé, Cenolé ferrugineux, Vin ferrugineux, *Fr. Cod.*; Eisenwein, *G.*

* "Iron and Ammonium Citrate, *forty grammes* [or 1 ounce av., 334 grains]; Tincture of Sweet Orange Peel, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Syrup, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; White Wine, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Iron and Ammonium Citrate in *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of White Wine. Add to this the Tincture of Sweet Orange Peel, and the Syrup, and, lastly, enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Set the mixture aside for two days; then filter through paper, in a well-covered funnel." *U. S.*

"Iron and Ammonium Citrate, 160 grains or 18.3 grammes; Orange Wine, *a sufficient quantity*. Dissolve the Iron and Ammonium Citrate in sufficient Orange Wine to form *one pint* (Imperial measure) or one thousand cubic centimetres. Agitate occasionally for three days; filter." *Br.*

Care must be observed not to confound this preparation with the "*Vinum Ferri*" of the British Pharmacopœia (see next article), which is a very different preparation. The name "*Vinum Ferri*" was adopted by the *U. S. P.* (8th Rev.) for the "*Vinum Ferri Citratis*" of the *U. S. P.* 1890.

This chalybeate preparation was made official by the *U. S. P.* 1880; previous to that time it had varied much in composition, from the lack of an authoritative formula.

Dose, one fluidrachm (3.75 *Cc.*), containing about two and a quarter grains of the iron salt; of the British wine of iron citrate, one to four fluidrachms (3.75 to 15 *Cc.*).

VINUM FERRI. Br.

IRON WINE

(vī'nūm fēr'ri)

Vinum Chalybeatum, s. Martiatum; Eisenwein, Stahlwein, *G.*

"Iron, in wire, 1 ounce (Imperial) or 50 grammes; Sherry, 1 pint (Imp. meas.) or 1000 cubic centimetres. Set aside for thirty days in a closed vessel, the Iron wire being almost, but not quite, immersed in the Sherry, the vessel being frequently shaken, and the stopper occasionally removed; filter." *Br.* (See also *Vinum Ferri* above.)

When wine is made to react on metallic iron with presence of air, the metal is oxidized, and then unites with the excess of acid of the potassium bitartrate, which is the characteristic salt of wines. The ferruginous salt, therefore, formed is iron and potassium tartrate, or the tartarated iron of the *Br. Pharmacopœia*, and this was the old method of preparing the Wine of Iron. But it is obvious that the strength in iron cannot be entirely uniform, as the quantity dissolved must depend on the proportion of the bitartrate in the wine, which is variable, and on various circumstances of the manipulation. In consideration of these objections, it was thought best, in the *Br.* formula of 1864, to substitute a simple solution in the wine of the iron and potassium tartrate already formed, and to abandon the old tedious formula. But it is obvious that a solution of the ferruginous salt in wine is not exactly the same as the wine of iron prepared with the metal, as it contains the potassium bitartrate unaltered. For this and other reasons, the *Br. Pharmacopœia* has returned to the old method.

Dose, one to four fluidrachms (3.75 to 15 *Cc.*).

VINUM FERRI AMARUM. U. S.

BITTER WINE OF IRON

(vī'nūm fēr'ri a-mā'rūm)

Vinum Chinæ Ferratum; Vin (Cenolé) de Quinquina ferrugineux, *Fr. Cod.*; Bitter Eisenwein, China-eisenwein, *G.*

* "Soluble Iron and Quinine Citrate, *fifty grammes* [or 1 ounce av., 334 grains]; Tincture

of Sweet Orange Peel, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Syrup, *three hundred cubic centimeters* [or 10 fluidounces, 69 minims]; White Wine, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Dissolve the Soluble Iron and Quinine Citrate in *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of White Wine. Add to this the Tincture of Sweet Orange Peel and the Syrup, and, lastly, enough White Wine to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Set the mixture aside for two days; then filter through paper, in a well-covered funnel." U. S.

Bitter wine of iron, made official in the U. S. P. 1880, has been very largely used in this country, although the objections to the introduction of elixirs into the Pharmacopœia might be made with equal force to its acceptance. It is a mild ferruginous tonic, a fluidounce representing twenty-two grains of iron and quinine citrate of official strength.¹

Dose, from two to four fluidrachms (7.5 to 15 Cc.).

VINUM IPECACUANHÆ. U. S., Br.

WINE OF IPECAC

(vīnūm ip-ē-căc-ū-ăn'hæ)

Ipecacuanha Wine; Vin (Ænolē) d'Ipēcacuanha, Fr.; Brechwurzelwein, G.

* "Fluidextract of Ipecac, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; White Wine, *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims], to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix them. Set the mixture aside for two days; then filter through paper, in a well-covered funnel." U. S.

"Liquid Extract of Ipecacuanha, 1 fl. ounce (Imperial measure) or 50. cubic centimetres; Sherry, 19 fl. ounces (Imp. meas.) or 950 cubic centimetres. Mix; set aside for forty-eight hours; filter." Br.

The preparations of the two Pharmacopœias are not of the same strength,—the U. S. wine

containing in a fluidounce the virtue of about 45 grains, the British of only somewhat more than 22 grains. Wine of ipecac possesses all the medicinal properties of the root, and may be used as a substitute when it is desirable to administer the medicine in a liquid form. As it is milder, without being less efficacious, than antimonial wine, it is preferable as an emetic. It is also much used as an expectorant and a diaphoretic, and the effects of the Dover's powder may be obtained by combining it with a liquid preparation of opium.

Dose, as an emetic for an adult, a fluidounce (30 Cc.); as an expectorant and a diaphoretic, from ten to thirty minims (0.6 to 1.8 Cc.). A fluidrachm (3.75 Cc.) may be given as an emetic to a child one or two years old, and repeated every fifteen minutes until it operates.

VINUM OPII. U. S.

WINE OF OPIUM [Sydenham's Laudanum]

(vīnūm ō'pī-i)

Laudanum de Sydenham, Vin d'Opium composé, Fr. Cod.; Tinctura Opii Crocata, P. G.; Safranhaltige Opiumtinktur, G.; Vino opiato composto, It.; Vino de opio compuesto, Sp.

* "Granulated Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Saigon Cinnamon, in No. 60 powder, *ten grammes* [or 154 grains]; Cloves, in No. 30 powder, *ten grammes* [or 154 grains]; Alcohol, White Wine, each, *a sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Alcohol and *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of White Wine. Macerate the Opium, Saigon Cinnamon, and Cloves in a stoppered container, in a moderately warm place, with *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of this menstruum, during seven days, with occasional agitation; then filter through purified cotton, in a well-covered funnel, returning the first portions until the filtrate passes perfectly clear, and finally pass enough menstruum through the residue to make the liquid measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

Wine of opium now contains the virtues of one grain of granulated opium in about 10 minims. The British wine of opium (1885) contained 22 grains of extract of opium, nearly, in 1 fluidounce, so that each fluidrachm contained about half a grain of morphine.

The wine made according to the directions of the U. S. P. (8th Rev.) is a vinous tincture of opium and no assay process is appended because the presence of the aromatics interferes with the accurate extraction of the morphine. The aromatic additions are thought to adapt it to certain states of the stomach or system in which laudanum is found to produce unpleasant effects. On being long kept it deposits insoluble

¹ Bitter Wine of Iron.—The following formula, in which Calisaya bark and gentian are used, is said by Chas. L. Mitchell to yield an elegant preparation: Take of ground Calisaya Bark 192 grains; ground Gentian Root 128 grains; Soluble Ferric Citrate 192 grains; Sherry Wine 13 fluidounces; Brandy 1 fluidounce; Alcohol 1 fluidounce; Oil of Orange 12 minims; Sugar 2 ounces; Solution of Iron Tersulphate 2 fluidounces; Ammonia Water q. s. Dissolve the Oil in the Alcohol and mix with the Sherry Wine and Brandy. Percolate with this the ground drugs, recover 15 fluidounces of tincture by pouring on water. Dilute the Iron solution with twice its bulk of water, and add Ammonia in slight excess. Wash and drain the precipitate thoroughly. Mix this with the tincture, and agitate occasionally until a filtered portion has a light yellow color and does not precipitate with tincture of Ferric Chloride. Filter, dissolve the Ferric Citrate and Sugar, and bring up the measure with a little water to 16 fluidounces; a fluidounce represents 12 grains of Calisaya Bark, 8 grains of Gentian Root, and 12 grains of Ferric Citrate. Dose, from one to three fluidrachms (3.75 to 11.25 Cc.).

matter, a sample of which Bihot of Malines, has shown to consist mainly of narcotine, with possibly a little codeine, without any discoverable trace of morphine. (*J. P. C.*, xxx. 200.) Ware recommended it as a local application to the eye in the latter stages of *ophthalmia*, when the vessels of the conjunctiva still remain turgid with blood. Two or three drops are introduced into the eye every morning until the redness disappears.

Dose, of wine of opium, five to ten minims (0.3 to 0.6 Cc.).¹

VINUM QUININÆ. Br.

QUININE WINE

(vī'nūm quī-nī'næ)

Vin (Cenolé) de Quinine, *Fr.*; Chininwein, *G.*

"Quinine Hydrochloride, 20 grains or 2 grammes; Orange Wine, 1 pint (Imperial measure) or 875 cubic centimetres. Dissolve; set aside; filter if necessary." *Br.* The *Br. Ph.* 1898 replaced quinine sulphate used in the 1885 process by quinine hydrochloride on account of the greater solubility of the latter. Each fluidounce contains one grain of quinine hydrochloride.

Dose, one-half to one fluidounce (15 to 30 Cc.).

VINUM RUBRUM. U. S.

RED WINE

(vī'nūm rû-brūm)

"An alcoholic liquid, made by fermenting the juice of fresh red-colored grapes, the fruit of *Vitis vinifera* Linné (Fam. *Vitaceæ*), in presence of their skins, and subjected to the usual cellar-treatment for fining and aging. When Red Wine is prescribed without further specification, it is recommended that a dry Red Wine of domestic production be employed. Red Wine should be preserved in well-closed casks filled as full as possible, or in well-stoppered bottles, in a cool place." *U. S.*

Vin rouge, *Fr.*; Rothwein, *G.*; Vino tinto, *Sp.*

Wine is the fermented juice of the grape, the fruit of *Vitis vinifera* of botanists. The juice of sweet grapes consists of a considerable quantity of grape sugar, certain nitrogenized principles, which act as ferments when the proper conditions are developed, and a small portion of extractive, tannic acid, potassium bitartrate, calcium tartrate, common salt, and

potassium sulphate, the whole dissolved or suspended in a large quantity of water. Sour grapes contain, in addition, a peculiar acid isomeric with tartaric, called *racemic acid*. (See page 85.) Grape juice, therefore, embraces all the ingredients essential to the production of the vinous fermentation, and requires only the influence of the atmosphere and a proper temperature to convert it into wine.

Owing to the growing excellence in quality of American wines, the Committee of Revision of the U. S. P. 1880 decided to abandon the former titles *Vinum Xericum* and *Vinum Portense*, to adopt the old titles *Vinum Album* and *Vinum Rubrum*, and to permit any wine to be used, whether American or foreign, provided it complies with the requirements of alcoholic strength and purity. The British Pharmacopœia 1898 makes *Vinum Xericum* the only official unmedicated wine, defining it simply as "a Spanish wine," but providing that it shall contain not less than 16 per cent. of alcohol by volume.

Preparation.—The juice expressed from the ripe grapes by various methods runs into vats and constitutes the "*must*." The temperature of the air being about 15.5° C. (60° F.), fermentation gradually takes place in the must, and becomes fully established after a longer or shorter period. In the meantime, the must becomes sensibly warmer, and emits a large quantity of carbon dioxide, which causes the more solid parts to be thrown to the surface in a mass of froth having a hemispherical shape called the *head*. The liquor from being sweet becomes vinous, owing to the conversion of the grape sugar into alcohol. After a while the fermentation slackens, when it becomes necessary to accelerate it by thoroughly mixing the contents of the vat. When the liquor has acquired a strong vinous taste and become perfectly clear, the wine is considered formed, and is racked off into casks. But even at this stage of the process the fermentation continues for several months longer. During the whole of this period a frothy matter is formed, which for the first few days collects around the bung, but afterwards precipitates along with coloring matter and tartar, forming a deposit which constitutes the wine-lees.¹

Division and Nomenclature.—Wines, according to their color, are divided into the red

¹ *Rousseau's laudanum* is a tincture of opium made with very weak alcohol, according to the following formula: "Take of White Honey twelve ounces; Warm Water three pounds. Having dissolved the honey, set the solution aside in a warm place; and, as soon as fermentation begins, add of selected opium four ounces, previously dissolved in twelve ounces of water. Allow the mixture to stand for a month at the temperature of 24° Réaumur (86° F.); then strain, filter, and evaporate to ten ounces; finally strain, and add four ounces and a half of alcohol of 20° B. Seven drops contain about a grain of opium." (*Pharm. Univ.*, ii. 265.)

¹ In certain parts of France the wine makers are in the habit, during the fermentation of the wines upon the marc, of adding plaster of Paris, under the impression that it improves the color and insures the stability of the wines. The process is called by the French *plâtrage*. It has the drawback of increasing the percentage of potassium sulphate notably, and its practice is now controlled by law in France. Other methods of treatment are the addition of dicalcium phosphate, known as *phosphotage*, and neutralizing the excess of acidity in the must by the addition of marble dust, known as *chaptalization*. The addition of sugar and water to the must is called *gallization*, and the addition of glycerin to the finished wine is known as *scheelization*. For fuller particulars, see *Sadtler's Industrial Chemistry*, 3d ed., p. 206.

and the white, and, according to their taste and other qualities, are either spirituous, sweet, dry, light, sparkling, still, rough, or acidulous. *Red wines* are derived from the must of black grapes, fermented with their skins and seeds, or what is collectively called the *marc*; *white wines*, from white grapes, or from the juice of black grapes, fermented apart from the marc. The coloring matter of the grape is almost insoluble in water, and hence the juice of the red grape is nearly colorless, and will produce a white wine if fermented alone, but when fermented with the presence of the grape the alcohol generated dissolves the coloring matter, which is soluble in that liquid, and thus the wine becomes red. The other qualities of wines depend on the relative proportions of the constituents of the must, and on the mode in which the fermentation is conducted. The essential ingredients of the must, as a fermentable liquid, are water, sugar, and a ferment. The exact composition of the must is shown by the analysis of must given below,¹ obtained from different sources and ranging through a number of years.

If the juice be very saccharine, and contain sufficient ferment to sustain the fermentation, the conversion of the sugar into alcohol will proceed until checked by the production of a certain amount of the latter, and there will be formed a *spirituous* or *generous* wine. If, while the juice is highly saccharine, the ferment be deficient in quantity, the production of alcohol will be less, and the redundancy of sugar proportionately greater, and a sweet wine will be formed. It is stated by M. G. Fleury that levulose undergoes the vinous fermentation much less readily than glucose, and that the sugar of sweet wines is chiefly levulose. Whether a grape yields a sweet or a dry wine seems, then, to depend, to some extent, upon the character of its sugar. (*J. P. C.*, 4e sér., viii. p. 323.) When the sugar and ferment are in considerable amount, and in the proper relative proportions for mutual decomposition, the wine will be strong-bodied and sound, without marked sweetness or acidity, and of the kind called *dry*. A small proportion of sugar can give rise only to a small proportion of alcohol, and consequently the less saccharine grapes will generate a comparatively weak or *light wine*, which will be sound and stable in its constitution in case the ferment is not in excess, but otherwise liable to pass into the acetous fermentation and become sharp. In case the wine is bottled before the fermentation is fully completed, the process will go on slowly in the

bottles, and the carbon dioxide generated, not having vent, will impregnate the wine and render it effervescing and *sparkling*. The *rough* or *astringent* wines owe their flavor to a portion of tannic acid derived from the marc of the grape, and the *acidulous* wines to the presence of carbon dioxide, or of an unusual proportion of tartar. Several of the above qualities often coexist. Thus, a wine may be spirituous and rough, sweet and rough, light and sparkling, etc. Wines are made in many countries, and are known in commerce by various names, according to their source. Thus, *Portugal* produces Port and Lisbon; *Spain*, Sherry, San Lucar, Malaga, and Tent; *France*, Champagne, Burgundy, Hermitage, Vin de Grave, Sauterne, and Claret; *Germany*, Hock and Moselle; *Hungary*, Tokay; *Sicily*, Marsala or Sicily Madeira, and Lisa; the *Cape of Good Hope*, Constantia; *Madeira* and the *Canaries*, Madeira and Teneriffe.

In the United States the first attempt to manufacture wine, on an extended scale, was made towards the close of the last century, at Spring Mill, near Philadelphia, by Peter Legaux, agent of the Pennsylvania Vine Company, and proved unsuccessful. The native grape found most suitable by the Company, after the foreign had failed on account of the climate, was the *Schuylkill muscatel* grape. The next attempt was made by the Swiss at Vevay, Indiana, with the *Schuylkill* grape, and was partially successful, a rough red wine being manufactured which met with a ready sale in the neighboring States. In a very few years the manufacture of this wine languished, foreign wines superseding it. The foreign grape, after numerous trials, not succeeding as a wine grape, investigations were undertaken to determine the adaptation of our various native grapes for making wine. Among these the *Catawba* grape, a native of North Carolina, introduced to public notice by Major Adlum of Washington City, about 1825, has been largely cultivated in Southern Ohio as a wine grape. The chief objection to it is its liability to the rot. Within a few years various other varieties of grape have come into vogue, and native wines are constantly improving in quality. The climate of Texas is peculiarly favorably to the growth of the grape vine. The *El Paso* grape is found in the vicinity of the falls of the Rio Grande, and the *great mustang* grows luxuriantly in every part of the State, and yields a superior red wine. California produces an immense amount of wine, which is now coming into general use. Considering its advantages

¹ Composition of Wine-must.	Sp. Gr.	Water, Per Cent.	Nitrogenous Material.	Sugar.	Acid.	Other Non- nitrogenous Material.	Ash.
Minimum	1.0690	51.53	0.11	12.89	0.20	1.68	0.20

Germany	48.4		
Bulgaria	46.2	Total	3881.9

(*J. Soc. Chem. Ind.*, 1905, p. 1329.)

Properties.—Wine, considered as the name of a class, may be characterized as a spirituous liquid, resulting from the fermentation of a fruit juice, or, in its more restricted use, of a grape juice, and containing coloring matter, and other substances, either combined or intimately blended with the spirit. It always contains a small proportion of aldehyde. All its other qualities vary with the nature of each particular wine. The principal varieties of foreign wines are briefly characterized below. *American* wines are classed as Sherries, Ports, Dry Red, Dry White, Champagnes, Sweet Catawbas, and special brands.

¹ There can be no doubt that the California wines are steadily advancing in quality, and that many of them now rival the European wines of high class. At the French Exposition (1889) a California wine made from the Carbenet Sauvignon grape of the Château-Lafitte type received the highest award for excellence over all other wines offered in competition, including the finest vintage of France, while the second award for brandies was also given to a California product. J. De Barth Shorb, late President of the California State Viticultural Commission, informed us, as the results of numerous analyses made under the auspices of the Commission, that the California red wines or clarets average from 10 to 14 per cent. of alcohol, the white wines 8 to 12 per cent., the ports 18 to 22 per cent., the sherries 17 per cent. The grapes of which these wines are made are not native to California, as is often thought, but are the offspring of cuttings originally introduced from France, Germany, Spain, and Italy. The so-called "Mission grape," of California, is evidently of Spanish origin, having been brought over by Roman Catholic missionaries in the early history of the country. It varies so much in different localities that it probably comes from various original stocks. Shorb states that while there are really some hundreds of varieties of grapes recognized by the viticulturists of California, the following are most esteemed. All are foreign grapes except the Lenoir, an American grape, which has been introduced into France, where it is known as Le Jacques:

Red Wines, Clarets.

Carbenet Sauvignon.
Burgundy Varieties.
Carignan.
Metaro.
Grenache.
Zinfandel.
Black Malvoisie.
Lenoir.

White Wines, Hocks.

Sauvignon Vert.
Riesling.
Golden Chasselas.
Bergher.

Brandies.

Old Mission.
Follé Blanche (Cognac grape).
Trousseau.
Charbonneau.
Black Burgundy.
Pedro Ximenes.
All the white varieties.
For raisins: Muscat of Alexandria and Gordo Blanco.
See also *Bulletin No. 72*, U. S. Dept. Agriculture, Bureau of Chemistry.

Sherry (*Vinum Xericum*, Br. 1898, U. S. 1870) is of a deep amber color, and when good possesses a dry aromatic flavor and fragrance, with very little acidity. It is officially defined as "a Spanish wine," and described as "a pale yellowish-brown liquid containing not less than 16 per cent. of ethyl hydroxide by volume." Br. It is prepared in the vicinity of Xeres, in Spain, whence its English name *sherry*. This wine is supposed to have been the *sack* of Shakespeare, so called from the word *sec* (dry). Henry Long has found about a grain of sulphuric acid in an ounce and a half of sherry wine, and supposes it to be free, but in the light of the experiments of Bussy and Buignet it is, we think, more likely to be in the state of potassium bisulphate, resulting from the reaction between potassium bitartrate and calcium sulphate used in preparing the wine. (*P. J.*, 1867, 732.)

Port (*Vinum Portense*, U. S. 1870) is of a deep purple color, and in its new state is a rough, strong, and moderately sweet wine. When kept a certain time in bottles, it deposits a considerable portion of its astringent matter, loses the greater part of its sweetness, acquires more flavor, and retains its strength. If too long kept, it deposits the whole of its astringent and coloring matter, and becomes deteriorated. Considerable quantities of brandy are usually added to it, which causes its heating quality on the palate. It is one of the strongest wines in common use. According to Muspratt of Liverpool, the alcohol in genuine port never exceeds 19 per cent. (*M. T. G.*, 1856, p. 355.)

Madeira was the strongest of the white wines formerly in use. It was somewhat acid, and, when of proper age and in good condition, had a rich, nutty, aromatic flavor. It rarely occurs in the market, however, and is of very variable quality, on account of the adulterations and admixtures to which it is subjected after importation.

Teneriffe is a white wine, of a somewhat acid taste, and, when of good quality, of a fine aromatic flavor. Its average strength is about the same as that of sherry. It is made from the same grape as Madeira, to which it bears a close resemblance.

Claret, called in France *vin de Bordeaux*, from its being produced near that city, in the district of Médoc, is a red wine, and from its moderate strength is ranked as a light wine. It has a deep purple color, and, when good, a delicate taste, in which the vinous flavor is blended with some acidity and astringency. The most esteemed kinds are the clarets called *Château-Margaux*, *Château-Lafitte*, and *Château-Latour*. Another celebrated variety is the *Château-Haut-Brion* of the Pays de Grave. Claret is the French wine most extensively consumed in the United States.

Official Requirements.—The U. S. Pharmacopœia (8th Rev.) does not recognize any special variety of wine, but only the general classes of white and red. (See page 1334). In

selecting wines for pharmaceutical purposes the apothecary should see that they conform to the following description and tests of the Pharmacopœia. *White Wine* is "a pale amber-colored or straw-colored liquid, having a pleasant odor free from yeastiness, and a fruity, agreeable, slightly spirituous taste without excessive sweetness or acidity. The specific gravity, at 15.6° C. (60° F.), should not be less than 0.990, nor more than 1.010. If a portion of White Wine be evaporated, the residue, when dried during twelve hours on a water-bath, should amount to not less than 1.5 nor more than 3 percent.; this residue ignited at a low temperature and burned gradually to whiteness, moistened with a small portion of ammonium carbonate T.S., and again carefully ignited, should weigh not less than 0.14 Gm. nor more than 0.26 Gm. for each 100 Cc. of White Wine tested. To neutralize 50 Cc. of White Wine should require not less than 3 nor more than 5.2 Cc. of normal potassium hydroxide V.S. (limit of *free acid*), litmus T.S. being used as indicator. If 10 Cc. of White Wine be diluted with an equal volume of water, and treated with 5 drops of ferric chloride T.S., only a faint, greenish-brown color should make its appearance (absence of more than traces of *tannic acid*). If 75 Cc. of White Wine be acidified with 5 Cc. of diluted sulphuric acid (1 in 3), and thoroughly shaken in a separator with a mixture of equal parts of petroleum benzin and ether, and if the solvent, after separation, be transferred to a porcelain dish, allowed to evaporate spontaneously, and the residue dissolved in 3 Cc. of water, the solution should not have a sweet taste (absence of *saccharin*), nor should it give a violet color upon the addition of a diluted solution of ferric chloride (1 in 200) (absence of *salicylic acid*).

Tested by the following method, White Wine should be found to contain not less than 7 percent. nor more than 12 percent., by weight (equivalent to 8.5 percent. to 15 percent. by volume), of absolute alcohol: Take the specific gravity (to four decimals) of a sufficient portion of the White Wine carefully measured at the temperature of 15.6° C. (60° F.), evaporate the Wine in a tared dish to one-third of its original weight, cool, and add water until the liquid measures its original volume at 15.6° C. (60° F.); then take the specific gravity (to four decimals) again. The difference between the two specific gravities deducted from 1.0000 corresponds to the specific gravity of an alcohol containing the same percentage of absolute alcohol, by weight or volume, as the Wine under examination, the corresponding percentage being ascertained by referring to the alcohol tables. (See PART III.)" U. S. "Pale yellowish-brown, containing not less than 16 per cent. of ethyl hydroxide by volume. When a mixture of 50 cubic centimetres of this wine and 50 cubic centimetres of water, acidulated with 5 cubic centimetres of the volumetric solution of sulphuric acid, is distilled, the distillate, after rejection of the first 10 cubic centimetres, shaken

with ether, the ethereal liquid separated and its ether removed by evaporation, the residue should not yield a violet coloration when mixed with test-solution of ferric chloride (absence of *salicylic acid*)." Br. *Red Wine* is "a deep red liquid, having a pleasant odor free from yeastiness, and a fruity, moderately astringent, pleasant, and slightly acidulous taste, without excessive sweetness or acidity. The specific gravity, at 15.6° C. (60° F.), should not be less than 0.989 nor more than 1.010. If a portion of Red Wine be evaporated, the residue, when dried during twelve hours on a water-bath, should amount to not less than 1.6 percent. nor more than 3.5 percent.; this residue, ignited at a low temperature and burned gradually to whiteness, moistened with a small portion of ammonium carbonate T.S., and again carefully ignited, should weigh not less than 0.22 Gm. nor more than 0.34 Gm. for each 100 Cc. of Red Wine tested. To neutralize 50 Cc. of Red Wine should require not less than 3 Cc. nor more than 5.2 Cc. of normal potassium hydroxide V.S. (limit of *free acid*), litmus T.S. being used as indicator. If 10 Cc. of Red Wine be diluted with an equal volume of water, and treated with 5 drops of ferric chloride T.S., the liquid should acquire a brownish-green color (presence of *tannic acid*). With lead acetate T.S. Red Wine forms a heavy precipitate which may vary in color from bluish-green to green. If 50 Cc. of Red Wine be treated with a slight excess of ammonia water, the liquid should acquire a green or brownish-green color; if it be then well shaken with 25 Cc. of ether, the greater portion of the ethereal layer removed, and evaporated in a porcelain dish with an excess of acetic acid and a few fibres of uncolored silk, the latter should not acquire a crimson or violet color (absence of *red aniline colors*). If 25 Cc. of Red Wine, heated to about 45° C. (113° F.), be well agitated with 25 Gm. of manganese dioxide, the liquid filtered off and acidulated with hydrochloric acid, it should not acquire a red color (absence of *acid fuchsine*). If 75 Cc. of Red Wine be acidified with 5 Cc. of diluted sulphuric acid (1 in 3) and thoroughly shaken in a separator with a mixture of equal parts of petroleum benzin and ether, and if the solvent after separation be transferred to a porcelain dish, allowed to evaporate spontaneously, and the residue dissolved in 3 Cc. of water, the solution should not have a sweet taste (absence of *saccharin*), nor should it give a violet color upon the addition of a diluted solution (1 in 200) of ferric chloride (absence of *salicylic acid*).

Tested by the following method, Red Wine should be found to contain not less than 7 percent. nor more than 12 percent., by weight (equivalent to 8.5 percent. to 15 percent. by volume), of absolute alcohol: Take the specific gravity (to four decimals) of a sufficient portion of the Red Wine accurately measured at the temperature of 15.6° C. (60° F.), evaporate the Wine in a tared dish to one-third of its

original weight, cool, and add water until the liquid measures its original volume at 15.6° C. (60° F.); then take the specific gravity (to four decimals) again. The difference between the two specific gravities deducted from 1.0000 corresponds to the specific gravity of an alcohol containing the same percentage of absolute alcohol, by weight or volume, as the Wine under examination, the corresponding percentage being ascertained by referring to the alcohol tables. (See PART III.)" *U. S.*

The official method of ascertaining the alcoholic strength is based upon the following plan of Horsley's. Note the specific gravity of the wine. Then take 5 fluidounces of it, boil it down in a flask to 2 fluidounces, and allow it to cool. All the alcohol is thus driven off. Add to the residuary liquid sufficient distilled water to bring it to the original measure of 5 fluidounces, and ascertain the specific gravity of the mixture. Deduct the excess of its specific gravity over 1.000, which is the specific gravity of distilled water, from the specific gravity of the wine as at first noted, and the difference will be the specific gravity of the alcohol and water in the wine. Then by consulting the tables giving the percentage in alcohol of liquids containing alcohol and water the percentage of alcohol in the wine will be obtained. Thus, suppose the specific gravity of the wine to be 0.997, and that of the liquid, after treatment as directed, 1.020. Then 0.020, the excess of the latter specific gravity over that of water or 1.000, deducted from 0.997, gives 0.977 as the specific gravity of the mixed alcohol and water in the wine, which, by referring to the table in PART III, will be found to indicate a percentage by weight of 15.67 of absolute alcohol.

The intoxicating ingredient in all wines is the alcohol which they contain, and hence their relative strength depends upon the quantity of that substance entering into their composition. The alcohol, however, naturally in wine is so blended with its other constituents as to be in a modified state, which renders it less intoxicating and injurious than the same quantity of alcohol separated by distillation and diluted with water. This is hardly true of the alcohol which is usually added to wines by manufacturers.

H. Bence Jones has ascertained the acidity of equal bulks of foreign wines, except Teneriffe, expressed in grains of sodium hydroxide. The bulk taken was that of 1000 grains of water at 60° F., and the numbers express the extremes of acid: sherry, 1.95 to 2.85; port, 2.10 to 2.55; Madeira, 2.70 to 3.60; claret, 2.55 to 3.45. The same authority has determined the proportion of sugar to the ounce in sherry, port, and Madeira, expressed in grains: sherry, 4 to 18; port, 16 to 34; Madeira, 6 to 20. Claret contains no sugar. Assuming that the sugar becomes acid in the system, the order of acidity of these wines, beginning with the least acid, is claret, sherry, Madeira, and port. (*Chem. Gaz.*, Jan. 16, 1854, p. 35.)

Wines of great diversity of flavor, acidity, and alcoholic strength are produced in America; there seems to be no difficulty in procuring wines in the market of assured purity and freedom from dangerous adulteration, yet nearly all of them contain alcohol and sugar, which have been added for the purpose of either preserving the wine or improving its taste. Glycerin and glucose are frequently added to wines when they naturally lack body. Additional analyses of American wines, made in the U. S. Government Laboratory in 1884 and 1888, will be found in *Bulletin No. 13*, Part 3, of the U. S. Department of Agriculture.

Later analyses of California wines will be found in *Bulletins No. 59* and 72, Bureau of Chemistry, U. S. Department of Agriculture.

Christison considered it a mistake to suppose that wines become stronger by being kept a long time in casks. His experiments appear to prove the reverse. While wine is not rendered more alcoholic by age for some time, its flavor is improved, and its value thus increased. It becomes less acid, partly by the deposition of tartar, and probably also by the reaction between the acids and the alcohol resulting in the production of esters. Most light wines, if not fortified, finally spoil even when well bottled.

Composition.—Wines consist mainly of water and alcohol. They contain also volatile oil, *œnanthic ether*, grape sugar, sometimes glycerin in minute proportion (*J. P. C.*, Oct. 1859, p. 292), gum,¹ extractive, coloring matter, tannic, malic, phosphoric, carbonic, and acetic acids, potassium bitartrate (tartar),² and calcium tartrate. The volatile oil has never been isolated, but is supposed to be the cause of the delicate flavor and odor of wine, called the *bouquet*. According to F. L. Winckler, the bouquet depends upon the presence of a nitrogenous compound of a volatile organic acid with a volatile base, which has a different odor in different wines. *œnanthic ether* (ethyl acetate, caproate, and pelargonate) was discovered in wine by Pelouze and Liebig. It is obtained towards the end of the distillation of wine on the great scale for making brandy. It forms only one part in ten thousand of the wine. It is a colorless liquid, having a peculiar vinous odor, and a taste at first slight, but afterwards acid. It is considered to be identical with *pelargonic ether*, under which head, in PART II, it is more fully described. *œnanthic ether* must not be confounded with the substance which gives rise to the bouquet of wine. The other ingredients of wine, just enumerated, are sometimes present and sometimes absent.

¹ For a paper on the effect of gum upon the determination of the amount of glucose in wine, see *J. P. C.*, Oct. 1875, p. 274.

² Phipson has recognized in some wines, especially a red wine of Meudon and some clarets from Bordeaux, *acid potassium racemate* or *paratartrate*, which he distinguished by the shape of its crystals floating in the wine, and afterwards separated and examined chemically. The crystals are in octagonal tables, partially colored by the red matter of the wine. He considers its presence an evidence of good quality in the wine. (*J. P. C.*, 4e sér., III. 274, 1866.)

Thus, sugar is present in sweet wines, tannic acid in rough wines, and carbon dioxide in those that effervesce. The different kinds of wine derive their various qualities from the mode of fermentation, the nature of the grape, and the soil and climate in which it may have grown. The alcohol in pure wine is that which results from the vinous fermentation, and is intimately united with the other ingredients of the liquid, but with almost all the wines of commerce a portion of brandy is mixed, the state of union of which is probably different from that of the natural alcohol of the wine. By the British custom house regulations, 10 per cent. of brandy may be added to wines after importation, but to good wines not more than 4 or 5 per cent. is added.

Most wines on being kept form deposits, whether in the cask or in bottles. L. Pasteur divided these deposits into three kinds. 1. One consists of crystals of potassium bitartrate, of neutral calcium tartrate, or of a mixture of the two salts. This does not adhere to the sides of the vessel, but has sufficient weight to collect in a small bulk on repose. It is productive of little inconvenience physically, and has no injurious chemical effect on the wine. 2. A second deposit, often confounded with the first, but altogether distinct, is formed of the coloring substances which adhere to the sides of the bottles, especially the most dependent. It is owing to the oxidation, through the air, of the soluble coloring matters of the wine, which thus become insoluble. In consequence of its adhesion to the bottle, it allows the wine to be poured off quite clear. Its formation is generally coincident with improvement in the wine, which becomes at the same time lighter-colored, so that after many years the red wines, like port, will be almost as light as Madeira. 3. The third kind of deposit is the most troublesome and injurious. It consists of cryptogamic vegetations, which, in the opinion of Pasteur, give rise to all the alterations in wines commonly known as maladies. These never adhere to the sides of the bottle, unless confined by the coloring matter, which occurs very rarely. They are little bodies so light that the least movement of the bottle disturbs them and the liquid becomes turbid to a considerable extent. In a mere physical point of view, therefore, they are very inconvenient, by interfering with the decanting of the wine, while, acting as ferments, they cause great mischief not only by change of the principles of the wine, but also by adding to it new products, the direct result of their own action. As most wines are under their influence, the injury they produce in destroying the better qualities of wine is incalculable. (*J. P. C.*, 4e sér., 1865, ii. 40.) The remedy for this disorder in wines, suggested by Pasteur, is to destroy the cryptogams by the aid of heat. All that is necessary is, by means of a water bath, to expose the wine, in bottles, to a heat of 140° to 160° F.—Experience has shown that in this

way the wine soon clarifies itself, and keeps well afterwards, with an improved flavor. The process of heating their wines was to some extent employed by the ancients. Appert was the first in modern times to try it, and in fact it is nothing more nor less than his own peculiar process for preserving vegetable liquids. De Vergnette-Lamotte also experimented with wines with the same effect, but the theory of the change was first made known by Pasteur. (*Ibid.*, 1866, iii. 118.)

Adulterations.—Wines are very frequently adulterated, and counterfeit mixtures are often palmed upon the public as genuine wine. Free sulphuric acid in red wines cannot be detected by barium salts, for all wines contain a small quantity of the soluble sulphates. It may be discovered, however, by dropping the suspected red wine on a piece of common glazed paper containing starch. If the wine be pure, the spot, when dry, will be violet blue, and the paper unaltered in texture, but if the wine contain even a thousandth part of sulphuric acid, the paper will be spotted rose-red, and prove brittle and friable when slightly rubbed between the fingers. (Lassaigne, O. Henri, and Bayard.) Formerly the wine dealers were in the habit of putting litharge into wines that had become acescent. The lead oxide formed with the acetic acid, lead acetate, which, being sweet, corrected the defect of the wine, but at the same time rendered it poisonous. At the present day this criminal practice is wholly abandoned. The adulteration is readily detected by hydrogen sulphide, which causes a black and flocculent precipitate. Brande, among the numerous samples of wine of suspected purity which he examined, did not find one containing any poisonous ingredient fraudulently introduced. Lead, in minute quantity, may sometimes be detected, but it is derived invariably from shot in the bottle, or from some analogous source. Rhenish wines, when acid from the presence of free tartaric or acetic acid, may be restored by the addition of neutral potassium tartrate, which gives rise to the formation of cream of tartar. Spurious mixtures, frequently containing very little of the fermented juice of the grape, and which are sold as particular wines, may not be poisonous, but they are, notwithstanding, highly pernicious in their effects upon the stomach, and always produce mischief and disappointment when depended on as therapeutic agents. The wines most frequently imitated are port and Madeira; cider is often the chief ingredient in the spurious mixtures. *English port* is sometimes made of a small portion of real port, mixed with cider, juice of elderberries, and brandy, and rendered astringent with logwood and alum. According to Stracke, genuine wines do not contain salts of potassium in quantity sufficient to yield a precipitate with platonic chloride. If, therefore, a suspected wine be evaporated to dryness, and the extract, after being washed with alcohol so long as this is colored

by it, and then dissolved in water, give a precipitate with platonic chloride, the presence of cider may be suspected. (*J. P. C.*, Mai, 1862, p. 442.) By most dealers in wine, coloring is employed, made usually of elderberries and alum. The practice of coloring wines is very reprehensible. In France coloring is openly sold with impunity, and extensively employed, although the wine dealer who uses it is liable to fine and imprisonment.¹

The weaker wines often spoil by keeping. In this case they are prone to dissolve any tartar that may have been deposited, and have been found to contain propionic acid. The result is ascribed by Nicklés to a fermentative decomposition of the tartar. Of course in this state such wine contains potassium salts, and would not respond favorably to the test of platonic chloride. (*J. P. C.*, Août, 1862, p. 90.) Lactic acid is one of the products of the changes which take place in the spontaneous deterioration of wine, and Balard has succeeded in discovering the peculiar lactic acid ferment in spoiled wines. The appearance of this is preceded by that of globules similar to those of yeast, and after the completion of the lactic acid fermentation, and the commencement of the putrefactive, a throng of vibriones is observable. After the cessation of the vinous fermentation, and during the progress of that of lactic acid, all disengagement of gas ceases.²

Besides the grape, a number of other fruits yield juices susceptible of the vinous ferment-

tation. These are all wines; thus, *cider* is the wine obtained by fermenting the juice of the apple, *perry* is the fermented juice of the pear. Fruit wines may be distinguished from grape wines by the absence in the former of tartaric acid or its salts. The infusion of malt, also, is capable of undergoing this process, and by its fermentation are produced the so-called *malt liquors*,—i.e., *ale*, *porter*, *brown stout*, and *lager beer*. Of these malt liquors *lager beer* is produced by a slow fermentation at a low temperature; *porter*, *brown stout*, and *ale*, by a rapid fermentation at a high temperature. *Porter* and *brown stout* differ from *ale* in that some of the *malt* out of which they have been made has been partially charred, the torrefaction being carried further in the manufacture of *porter*, whence the dark color of the latter. Brande gives the following percentage of alcohol in certain wines and malt liquors: currant wine, 20.55; gooseberry wine, 11.84; orange wine, 11.26; elder wine, 8.79; cider, from 5.21 to 9.87; perry, 7.26; mead, 7.32; Burton ale, 8.88; Edinburgh ale, 6.20; brown stout, 6.80; London porter, 4.20; small beer, 1.28. In the manufacture of these minor wines sugar is often freely added to the liquor before fermentation, and it is evident that in this way has been obtained the excessive alcoholic strength of some of the wines examined by Brande. H. Bence Jones gives the following percentages of alcohol in the under-named liquors, cider, from 5.4 to 7.5; bitter ale, from 6.6 to 12.3; porter, from 6.5 to 7.0; brown stout, from 6.5 to 7.9. According to L. Hoffmann, Burton ale consists, in the 100 parts, of carbon dioxide 0.04, absolute alcohol 6.62, extract of malt 14.97, and water 78.37; and pale ale, of carbon dioxide 0.07, absolute alcohol 5.57, extract of malt 4.62, and water 89.74. All malt liquors contain, besides water and alcohol, solid substances, which together constitute the so-called extract,—i.e., that which is left behind when the alcohol and water are evaporated. The most important of these are dextrin, grape sugar, glycerin, succinic, acetic, lactic, propionic, and glucic acids, carbon dioxide, albumen and albuminous principles, bitter and resinous matters and essential oil from the hop, alkaline and earthy salts.

Uses.—As wine depends chiefly for its activity upon alcohol it may be used as a means of producing alcoholic stimulation in the various diseases or conditions in which such stimulation is indicated. It has, however, certain properties differing from those of simple alcohol, which make its substitution by a dilute alcohol very disadvantageous, and make its selection for use as contrasted with the stronger liquors, advantageous or disadvantageous according to the circumstances of the case. Owing perhaps chiefly to their ethereal constituents, the stronger wines, when dry, often agree better with digestion than do other alcoholic drinks; while the lighter wines, and especially the sweet or not dry wines, are prone to disarrange

¹ *The Detection of Coloring Matter in Wine.*—Alum may be detected in red wine by boiling it for a few minutes. If alum be present, even in 1-3000th part, the wine gradually becomes turbid, and furnishes a flocculent precipitate; while a pure red wine is not rendered turbid, even by long boiling. (*J. L. Las-saigne*.) Lapeyre states (*J. P. C.*, 4e sér., xi, 291) that logwood may be detected by means of bibulous paper which has been saturated with a neutral copperacetate; a strip of this, if dipped for a moment into natural wine, takes a gray or grayish rose color, but if logwood be present the tint will be a violaceous blue. M. de Cherville dissolves a piece of potassium hydroxide in the wine; if no sediment appear, and the wine become greenish, it is uncolored; if a precipitate fall, it has been colored; a violet sediment indicates elder or mulberries; red, beet root or Pernambuco wood; violet red, logwood; yellow, "phytolac" berries; violet blue, privet berries; pale violet, sunflower. (*P. M. T.*, iv, 639.) A. Dupré recommends that a small cube of jelly (prepared by dissolving 5 grammes of gelatin in 100 Cc. of warm water, and allowing to cool) be placed in the wine. After from 24 to 48 hours the jelly is removed and washed. If the coloring matter be artificial, it will have penetrated the whole cube; if it be natural, only the surface. *Nessler's reagent for wine* consists of 7 parts of alum and 10 parts of sodium acetate in 100 parts of water. Natural-colored wines are not affected by this. Artificial colors are altered to a dingy blue. (*Proc. A. Ph. A.*, xxvii, 213.)

² *Unfermented Wine.*—Under this misnomer the unfermented juice of the grape has had a large sale in America: it cannot properly be called wine, because the alcoholic fermentation is an essential part of wine making. Grape juice may be preserved by heating, in order to coagulate albuminous principles, filtering, and subsequently heating the bottles containing the filtrate to destroy micro-organisms; this process necessarily affects the flavor. Another method is to add a preservative like salicylic acid or boric acid to the grape juice, and to filter without the use of heat; this preserves the flavor, but is objectionable on account of the presence of the foreign bodies. Welch's *grape juice* is a preserved juice containing no alcohol and is not a wine.

digestion. The small amount of alcohol which they contain, in contrast especially with their cost, counts very strongly against their use when very active stimulation is desired, hence they are at present seldom employed in severe acute disease. On the other hand, their agreeable taste, and the immediate pleasantly stimulating action, something apart from that of simple alcohol, which many of them exert upon the nervous system, make them very useful in cases of convalescence and of chronic diseases with long continuing exhaustion. In such cases they should be taken with food.

In selecting a wine for any case especial attention should be paid to its constituents other than alcohol. Thus, in patients suffering from gouty or uric acid diathesis, sweet and sour wines are alike especially contra-indicated. Champagne is especially contra-indicated when there is a gouty diathesis and in certain cases of indigestion. On the other hand, in irritable stomach with a tendency to vomit of nervous origin, it often acts happily. Sour wines, sweet wines, champagne and even claret should usually be forbidden when there is a tendency to looseness of the bowels, port wine or brandy being preferred under these circumstances. In cases of acute adynamia, with markedly irritable stomach, wine whey sometimes affords a means of giving a delicate food and stimulant which will be taken when everything else is rejected. It is made by adding to a pint of boiling milk, just removed from the fire, from a gill to half a pint of white wine, straining without pressure to separate the curd, and sweetening if necessary for the taste of the patient; usually the less sugar the better the result.

The question of the habitual use of wine is so large a one as not to be capable of proper discussion at this place. The result of modern science may, however, be epitomized as showing that in persons who are well fed, especially who take an abundance of meat and other nitrogenous foods, the daily use of wine is not only unnecessary, but even when the amounts taken are moderate has a distinct tendency to deteriorate health and bring about serious disease and even death as the subject progresses towards middle life or old age. On the other hand, when people are underfed and habitually take a minimum amount of nitrogenous food, the use of wine may not only be not deleterious but distinctly helpful. To give a practical example, Americans, even of the so-called working classes, eat much more than is required by the needs of the system, and in this eating partake very largely of nitrogenous food, to them the daily use of wine is distinctly injurious. On the other hand, the Italian peasant, laboriously employed, with almost no food except bread, macaroni, or some other grain product, and the same article of food being often taken three times a day, is better off for the large quantity of light wine which he takes.

XANTHOXYLUM. U. S.

XANTHOXYLUM [Prickly Ash]

(xan-thôx'y-lûm)

"The dried bark of *Xanthoxylum americanum* Miller (Northern Prickly Ash), or of *Fagara Clava-Herculis* (Linné) Small (Southern Prickly Ash) (Fam. Rutaceæ)." U. S.

X. americanum: Toothache Tree, Angelica Tree, Suter-berry, Pellitory Bark, Yellow-wood; Clavaller, Frêne épineux, Fr.; Zahnwehholz, Zahnwehrinde, G. *Fagara Clava-Herculis*: Sea Ash, Hercules' Club, Pepper-wood.

Xanthoxylum americanum, Miller, *Gard. Dict.*, 8th ed., No. 2; Torrey and Gray, *Fl. of N. Am.* i. 214.—Northern Prickly Ash is a shrub from five to twenty-five feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface.

The flowers, which are small and greenish, are disposed in sessile umbels near the origin of the young shoots. The plant is polygamous, some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the pistils three or four in the perfect flowers, about five in the pistillate. The capsules are stipitate, oval, punctate, of a greenish-red color, with two valves, and one oval blackish seed. This species of xanthoxylum is indigenous, growing in woods and in moist shady places throughout the Northern, Middle, and Western States. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odor, recalling that of oil of lemon.

*Fagara Clava-Herculis*¹ (L.), Small; *X. Clava-Herculis*, L., *Sp. Pl.* (1753) 270; Gray, Chapman, Britton.—Southern Prickly Ash va-

¹ *X. americanum*, Miller, is the Northern prickly ash. *X. Clava-Herculis*, Lamarck (not Linné); *X. fraxinifolium*, Marshall; *X. fraxineum*, Willdenow; *X. mite*, Willdenow; *X. ramiflorum*, Michaux; *X. tricarpum*, Hooker; and *Thylao fraxineum*, Rafinesque. *X. Clava-Herculis*, Linné, the Southern prickly ash. *X. fraxinifolium*, Lamarck; *X. carolinianum*, Lamarck; *X. fraxinifolia*, Lamarck; *X. tricarpum*, Michaux; *X. aromatum*, Willdenow; *X. pseudopetalon glandulosum*, P. tricarpum, and *X. catesbianum*, the last four names being used by Rafinesque in his different writings.

Botanists are not agreed concerning the distinction of the genus *Fagara* from *Xanthoxylum*. Thus, the authors of the Index Kewensis consider the two genera identical, while Engler and Prantl separate them. The most important character separating them seems to be the absence of sepals in *Xanthoxylum*. Most of the species of the genus *Fagara* are tropical trees.

ries in size from a large bush to a small tree. Its bark is armed with warty prickles, and large prickles occur on the branches and the petioles. The alternate leaves have from seven to nine ovate-lanceolate, crenate-serrulate, unequal-sided leaflets, smooth and shining on the upper surface. It grows on dry soil, westward as far as Western Texas, and perhaps into Mexico, eastward to the Atlantic coast, and northward to Southern Virginia, especially affecting the coast region.

The fruits (*Prickly ash berries*) of both of the official species are possessed of medicinal activity and probably contain the same principles found in the barks.

There has been much confusion in regard to the nomenclature of the prickly ashes. *Aralia spinosa*, L., or angelica tree, which grows in the Southern States, is occasionally confounded with *F. Clava-Herculis*, in consequence partly of being sometimes called, like the latter, *prickly ash*. Its bark is nearly smooth externally, is beset with slender prickles in transverse rows and has a taste different from that of *F. Clava-Herculis*. Besides the official trees, the bark of *F. flava* (Vahl.), Frug. and Urban (*X. caribæum*, S. Wats.), the *satin-wood* of semi-tropical Florida and the West Indies, has appeared in commerce under the name of *yellow Hercules club* or *yellow thorn*. This bark is thin, with an odor like that of Angustura bark, a bitter, disagreeable, acrid taste, and a canary-yellow color, which it imparts to the saliva when chewed. It would seem, also, that under the name of *prickly yellow wood*, *yellow wood*, or *fustic*, the products of other West Indian xanthoxylums and allied plants find their way into commerce.

Xanthoxylum veneficum, Bailey, of Australia is, according to J. H. Maiden, a violent convulsive poison, 5 grains of the extract being a fatal dose for a cat. *Xanthoxylum scandens* is said to be used by the natives of Java as a fish poison, and according to Van der Haar, contains an alkaloid. (P. J., 71, 134; 73, 814.)

Properties.—Although the bark of the Southern prickly ash was not recognized by the U. S. Pharmacopœia until the revision of 1880, as long ago as 1864 Bridges pointed out that it had entered commerce, and gave the physical characteristics separating it. (*Proc. A. Ph. A.*) The characteristics of the two barks are very well given in the following official description.

"Northern Prickly Ash.—In curved or quilled fragments, about 1 Mm. thick; outer surface brownish-gray, with whitish patches, and minute, black dots, faintly furrowed, with some brown, glossy, straight, two-edged spines, linear at the base, and about 5 Mm. long; inner surface whitish, smooth; fracture short, non-fibrous, green in the outer and yellowish in the inner layer; inodorous; taste bitterish, very pungent.

Southern Prickly Ash.—In very large quills or sheets, 1 to 2 Mm. thick, externally of a light purplish-gray with large silvery-gray patches,

and marked by many large corky projections, frequently 2 Cm. high, which often bear stout brown spines; otherwise like the Northern Prickly Ash. *Xanthoxylum* should not be confounded with the bark of *Aralia spinosa* Linné (Fam. *Araliaceæ*), which is nearly smooth externally, and beset with slender prickles in transverse rows." U. S.

W. L. Cliffe after careful examination demonstrated that the bark of Southern prickly ash exceeded that of the Northern prickly ash in active properties. (A. J. P., 1901, 562.) In 1829, Edward Staples isolated from *X. americanum* a crystalline *xanthoxyline* which was again found by J. U. Lloyd in 1876. Subsequently, from the same plant Edward T. Moffet (A. J. P., 1886, 417) obtained a supposed alkaloid in yellow crystals, soluble in alcohol and chloroform, insoluble in petroleum benzin, ether, and benzene. G. H. Colton (A. J. P., 1880, p. 191) separated from the Southern prickly ash, tasteless, colorless, silky acicular crystals, soluble in alcohol, ether, and chloroform, less soluble in benzene, and insoluble in water. The identity of all these principles was assumed until E. G. Eberhardt (A. J. P., 1890, 231) obtained from the Southern prickly ash a colorless crystalline principle agreeing in solubilities with that of Colton. On analysis it gave figures indicating the formula $C_{20}H_{15}O_8$ or $C_{20}H_{25}O_8$. At the same time he analyzed a sample of Lloyd's crystalline principle from *X. fraxineum* (*X. americanum*, Mill.), which had been preserved in the cabinet of the Philadelphia College of Pharmacy, and found for it the formula $C_{20}H_{27}O_8$. Numerous reactions also indicated that the two principles were different. Thus, Lloyd's crystals dissolve in concentrated sulphuric acid with light red color, and on the addition of an excess of water produce a whitish precipitate which is taken up by chloroform; the crystals from the *F. Clava-Herculis*, dissolve in concentrated sulphuric acid with dark red color, and on dilution separate a purplish precipitate, which is not taken up by chloroform. Lloyd's principle melts, moreover, at 129.5° C., while Eberhardt's melts at 119° C. In 1863, J. D. Perrin separated from the Caribbean *Xanthoxylum Clava-Herculis* an alkaloid which he considered to be *berberine*. This had also been described as early as 1826 by Chevallier and Pelletan under the name of *xanthopierite*. *X. senegalense* (artar root) was analyzed by Giacosa and Soave (A. J. P., 1890, 500), who found a fixed oil, a neutral crystalline substance, melting at 120° C., and two alkaloids. The first of these they call *artarine*, and give to it the formula $C_{20}H_{17}NO_4$ (which makes it agree with *berberine*), or $C_{21}H_{23}NO_4$, in which case they consider that it may be *methylhydroberberine*. The second alkaloid, crystallizing in blood-red needles, they did not analyze.

Uses.—*Xanthoxylum* is stimulant, producing, when swallowed, a sense of heat in the stomach, with more or less general arterial excitement,

and a tendency to diaphoresis. It is thought to resemble mezereum and guaiac in its remedial action, and is given in the same diseases. As a remedy in *chronic rheumatism*, it enjoys some reputation in this country. The bark, used as a masticatory, is a popular remedy for *toothache*. *Xanthoxylum* is capable of being used as a counter-irritant, and great relief is sometimes afforded in various forms of chronic pelvic disease in women by means of a hot pack, applied to the lower part of the trunk, of two to four ounces of fluidextract of *xanthoxylum* and an ounce of tincture of cayenne pepper to two quarts of water. A decoction prepared by boiling an ounce in three pints of water down to a quarter may be given in the quantity of a pint (473 Cc.), in divided doses, during the twenty-four hours.

Dose, fifteen to thirty grains (1 to 2 Gm.).

Off. Prep.—Fluidextractum *Xanthoxyli*, *U. S.*

ZEA. U. S.

ZEA [Corn Silk]

(zē'ə)

"The fresh styles and stigmas of *Zea Mays* Linné (Fam. *Gramineæ*)." *U. S.*

Stigmata Maydis; Filament de Mais, *Fr.*; Maispistille, *G.*

This drug is the so-called "silk" of the ear of ordinary Indian corn or Maize, cultivated in the warmer temperate and subtropical countries of the world. It consists of "a matted mass of slender filaments, 5 to 15 Cm. long, thread-like, yellowish or brownish; nearly inodorous; taste faintly sweetish with a characteristic flavor." *U. S.* Rademaker and Fischer (*A. J. P.*, 1886, p. 369) determined the presence of 2.25 per cent. of *maizenic acid* in dried corn silk. It was first described, however, by Vauquier. It is freely soluble in water, alcohol, and ether, but insoluble in benzin. Rademaker and Fischer found, in addition to the acid, fixed oil, resin, chlorophyll, sugar, gum, extractive, albuminoids, phlobaphene salt, cellulose, and water.

Uses.—Zea has been highly recommended by various surgeons as a mild stimulant diuretic, useful in *acute* and *chronic cystitis*, and in the bladder irritation of *uric acid* and *phosphatic gravel*. It has also been employed in *gonorrhœa*, and has been affirmed by Landreux to be a useful diuretic and even cardiac stimulant in the *dropsy of heart disease*. It probably is, however, a feeble remedy comparable to tritium, an infusion of which (two ounces in a pint of boiling water) may be taken almost *ad libitum*, or whose fluidextract may be given in doses of one to three fluidrachms, every two or three hours.

Concerning the activity of *maizenic acid* we have little definite knowledge, but it probably represents whatever physiological power the drug possesses; it has been given in the dose of one-eighth of a grain (0.008 Gm.).

Dose, one to three drachms (3.9 to 11.6 Gm.).

ZINCI ACETAS. U. S., Br.

ZINC ACETATE

(zīn'ēi ā-cē'tās)

"It should contain in the uneffloresced condition not less than 99.5 percent. of pure Zinc Acetate [$(\text{CH}_3\text{COO})_2\text{Zn} + 2\text{H}_2\text{O}$], and should be kept in well-stoppered bottles." *U. S.* "Zinc Acetate, $\text{Zn}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 3\text{H}_2\text{O}$, is prepared by neutralizing acetic acid with zinc carbonate." *Br.*

Acetas Zincicus; Acétate de Zinc, *Fr. Cod.*; Zincum Aceticum, *P. G.*; Zinkacetat, Essigsäures Zink, Essigsäures Zinkoxyd, *G.*

In the *U. S.* process of 1870¹ the zinc oxide is acted upon directly by the acetic acid. During the evaporation of the solution of the zinc acetate, a small portion of the acetic acid is lost; and hence the necessity of acidulating with a few drops of acetic acid before crystallizing. Though not economical, these processes have the recommendation of being easily performed, and of yielding a pure product. In relation to zinc acetate, see a paper by Ambrose Smith, *A. J. P.* (vii. 14).

Properties.—Zinc acetate is in "soft, white, six-sided, monoclinic plates, of a pearly lustre, having a faintly acetous odor, and in dilute solutions an astringent, metallic taste. Exposed to the air, the salt gradually effloresces and loses some of its acid. Soluble in about 2.5 parts of water, and in 36 parts of alcohol at 25° C. (77° F.); soluble in 1.5 parts of boiling water, and in 0.6 part of boiling alcohol. On protracted boiling with water acetic acid is lost, and an insoluble basic salt formed. When heated, the salt is partially fused, losing water and acid. At a higher temperature it is decomposed, evolving acetone and other combustible vapors, and leaving a residue of zinc oxide. Its aqueous solution reddens blue litmus paper. The aqueous solution of the salt (1 in 20) yields, with potassium ferrocyanide T.S., a white gelatinous precipitate, and with ammonium sulphide T.S. a pure white precipitate. Ten Cc. of the aqueous solution of the salt (1 in 20), to which 1 Cc. of hydrochloric acid has been added, should not respond to the Time-Limit Test for *arsenic, cadmium, lead, and copper* (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted. The addition of a few drops of ferric chloride T.S. to an aqueous solution of the salt (1 in 20) produces a red color. Ammonium carbonate T.S., or potassium hydroxide

¹Take of Commercial Zinc Oxide two troyounces; Acetic Acid eight fluidounces and a half; Distilled Water five fluidounces. Mix the Acid and Water, and digest the Zinc Oxide in the mixture for half an hour, then heat to the boiling point, filter while hot, and set aside to crystallize. Drain the crystals in a funnel, and dry them upon bibulous paper. An additional quantity of crystals may be obtained by evaporating the mother-liquor to one-half, slightly acidulating with acetic acid, and crystallizing." *U. S.* 1870.

T.S., when added in small portions to the aqueous solution of the salt (1 in 20) produces at first a precipitate of a pure white color, which dissolves completely upon the addition of an excess of the reagent. The aqueous solution of the salt (1 in 20), after the addition of a few drops of diluted nitric acid, should remain clear upon the addition of either barium chloride T.S. (absence of *sulphate*) or silver nitrate T.S. (absence of *chloride*). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17)." U. S. "In thin translucent and colorless crystalline plates, of a pearly lustre, with a sharp unpleasant taste; soluble in 2.5 parts of *water*. It affords the reactions characteristic of zinc and of acetates. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, chlorides, or sulphates." Br.

The Br. Pharmacopœia gives in its formula for zinc acetate three molecules of water. Although the U. S. Pharmacopœia of 1880 adopted the formula giving to zinc acetate three molecules of water, Dibbit states that it contains but two molecules. Franchimont has confirmed this, and proved that both of these two molecules are lost at the temperature of 100° C. (212° F.). (*Ber. d. Chem. Ges.*, 1879, p. 11; *A. J. P.*, May, 1879.) The U. S. P. has adopted this view, and recognizes two molecules. The precipitate thrown down by ammonia from the pure salt is entirely redissolved by an excess of the precipitant, but if ferric oxide be present it will be left undissolved. Zinc acetate is decomposed by the mineral acids, with the escape of acetous vapors.

Uses.—Zinc acetate is used almost exclusively as a local remedy. It is employed principally as an astringent collyrium in *ophthalmia*, and as an injection in *gonorrhœa*, after the acute stage in these affections has passed. The strength of the solution usually prescribed is one or two grains to a fluidounce (0.065 or 0.13 Gm. to 30 Cc.) of distilled water.

ZINCI BROMIDUM. U. S.

ZINC BROMIDE

(zīn'cī brō'mī-dŭm)

$\text{ZnBr}_2 = 223.62$

"It should contain, when anhydrous, at least 97 percent. of pure Zinc Bromide, and should be kept in small, glass-stoppered bottles." U. S.

Zincum Bromatum; Bromure de Zinc, Fr.; Bromzink, Zinkbromid, G.; Bromuro zincico, Sp.

Zinc Bromide may be made either by the direct combination of zinc and bromine, or by dissolving zinc in a solution of hydrobromic acid. L. Lyons proposes to make this salt by dissolving potassium bromide and crystallized zinc sulphate, each, in the smallest quantity of

hot water, and mixing while hot. When the mixture has cooled, twice its bulk of alcohol is added, and the whole filtered through asbestos to separate the potassium sulphate. The filtrate is then evaporated to dryness.

Properties.—It is officially described as "a white, granular powder; odorless, having, even in dilute solutions, a sharp, saline and metallic taste. Very deliquescent. Readily soluble in water and alcohol. When heated to 394° C. (741.2° F.), the salt fuses, and, with a careful increase of heat, may be sublimed in the form of needle-shaped prisms. Its aqueous solution gives a slightly acid reaction with blue litmus paper. The aqueous solution of the salt (1 in 20) yields a pure white precipitate with hydrogen sulphide T.S. and ammonium sulphide T.S., and also with potassium ferrocyanide T.S. Silver nitrate T.S. produces a yellowish-white precipitate insoluble in nitric acid and in a moderate excess of ammonia water. If to 10 Cc. of the aqueous solution of the salt (1 in 20) 1 Cc. of chloroform be added, then chlorine water (which has been diluted with an equal volume of water), cautiously introduced, drop by drop, with constant agitation, the liberated bromine will dissolve in the chloroform, imparting to it a yellow to orange color, free from any violet tint (absence of *iodide*). On adding ammonium carbonate T.S. to the aqueous solution of Zinc Bromide, a white precipitate is produced, which should completely redissolve in an excess of the reagent. The aqueous solution of the salt (1 in 20), to which sufficient hydrochloric acid has been added to insure a clear solution, should not respond to the Time-Limit Test for *arsenic*, *cadmium*, *lead*, and *copper* (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted. Another portion of this aqueous solution should not be rendered turbid by the addition of barium chloride T.S. (absence of *sulphate*). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for *arsenic* (see PART III, Test No. 17). If 1 Gm. of Zinc Bromide be dissolved in 50 Cc. of acetic acid, 2 Gm. of lead dioxide (free from chloride) be added, and the mixture evaporated in a small beaker to at least 10 Cc., then the residue, diluted with 10 Cc. of distilled water and filtered, should give not more than a slight turbidity on the addition of 2 Cc. of nitric acid and a few drops of silver nitrate T.S. (limit of *chloride*). If 0.3 Gm. of the anhydrous salt be dissolved in 10 Cc. of water, and 2 drops of potassium chromate T.S. be added, it should require not less than 26 Cc. nor more than 26.8 Cc. of tenth-normal silver nitrate V.S. to produce a permanent red color, corresponding to not less than 97 percent. of the pure salt." U. S.

Uses.—Zinc bromide is capable in excessive doses of acting as an irritant poison. It has been commended in *epilepsy*, but is of no value.

Dose, one to two grains (0.065 to 0.13 Gm.).

ZINCI CARBONAS PRÆCIPITATUS.

U. S. (Br.)

PRECIPITATED ZINC CARBONATE

(zín'cí cār'bō-nās præ-cip-ī-tā'tūs)

"Hydrated Zinc Carbonate, which, upon ignition, should yield not less than 72 percent. of zinc oxide [$\text{ZnO} = 80.78$]." U. S. "Zinc Carbonate or zinc hydroxycarbonate, $\text{ZnCO}_3(\text{ZnH}_2\text{O})_2 \cdot \text{H}_2\text{O}$, is produced by the interaction of zinc sulphate and sodium carbonate." Br.

Zinci Carbonas, Br., Zinc Carbonate; *Zinci Carbonas Præcipitata, U. S. 1870*; Carbonate of Zinc; *Zincum Carbonicum, Carbonas Zincicus*; Carbonate (sous-) de Zinc Hydraté, Hydrocarbonate de Zinc, *Fr. Cod.*; Carbonate de Zinc, *Fr.*; Zinkcarbonat, *Kohlensaures Zinkoxyd, G.*

Calamina, U. S. 1850, was dropped from the U. S. Pharmacopœia in 1860 on account of its impurities, and in the 1880 revision the formula for its substitute was also omitted. In the U. S. formula of 1870¹ a double decomposition takes place between the salts employed, resulting in the formation of sodium sulphate in solution, and basic zinc carbonate which is precipitated. Sodium carbonate is preferable to potassium carbonate for decomposing the sulphate, since the former gives rise to sodium sulphate, which is more easily washed away than the potassium sulphate derived from the latter. Boiling water is properly used in the process, in order to obtain a pulverulent precipitate, which is readily washed. If cold solutions are used, a gelatinous precipitate is formed, which is washed with difficulty. When a solution of zinc sulphate is precipitated by an excess of acid potassium carbonate, a normal zinc carbonate is obtained. With normal sodium carbonate, on the other hand, taken as a precipitant, a basic salt results.

Properties.—It is officially described as "an impalpable, white powder, of somewhat variable chemical composition, without odor or taste. Permanent in the air. Insoluble in water or alcohol; completely soluble in diluted acids with copious effervescence; also soluble in ammonia water, and in ammonium carbonate T.S. When strongly heated, the salt loses water and carbon dioxide, and leaves a residue, which is yellow while hot, but becomes white on cooling. When a small portion of the salt is moistened with a drop of cobaltous nitrate T.S., and heated before the blow-pipe, it will assume a vivid green color. For making tests of identity and purity, make a solution by adding 10 Cc. of diluted sulphuric acid and 10 Cc. of water to 1.25 Gm. of the salt, and, after effervescence has ceased, remove the undissolved excess by filtration. In a portion of this solution a white gelatinous precipitate is produced by potassium

ferrocyanide T.S., and a pure white precipitate by ammonium sulphide T.S. Another portion of the solution, acidulated with hydrochloric acid, should not respond to the Time-Limit Test for arsenic, cadmium, lead, and copper (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted. Another portion of the solution should yield, with ammonium carbonate T.S., a white precipitate, which should redissolve completely in an excess of the reagent. If 1 Gm. of the salt be placed in a flask with 10 Cc. of boiling water, and 2 drops of phenolphthalein T.S. added, not more than 1 Cc. of tenth-normal hydrochloric acid V.S. should be required to discharge the red color (limit of alkali). One Gm. of Zinc Carbonate, after strong ignition in a porcelain crucible, should leave a residue of zinc oxide weighing not less than 0.720 Gm." U. S. "A white, tasteless, inodorous powder, insoluble in water, entirely soluble in diluted nitric acid. It affords the reactions characteristic of zinc and of carbonates. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, or ammonium, and only the slightest reactions with the tests for chlorides or sulphates." Br. If adulterated with chalk it will be only partly soluble in oxalic acid solution. Precipitated zinc carbonate is often sold under the incorrect name of *flowers of zinc*, a name which properly belongs only to the oxide, as obtained by combustion. When obtained from solutions of zinc sulphate and sodium carbonate it has a variable composition, as different hydrated basic carbonates are formed, according to the temperature used, etc.; the higher the temperature and the larger the quantity of water used, the more basic the carbonate becomes. According to the Br. Pharmacopœia, it consists, as thus prepared, of one molecule of zinc carbonate and two molecules of zinc oxide, with three molecules of water ($\text{ZnCO}_3 + 2\text{ZnO} + 3\text{H}_2\text{O}$). Its composition is sometimes stated as $(\text{ZnCO}_3)_2 \cdot 3\text{Zn}(\text{HO})_2 = 546.96$. The basic character of the salt official in the U. S. P. 1870 is explained by the fact that effervescence of carbon dioxide takes place on mixing the solutions.

Uses.—It is employed for the same purposes as prepared calamine, and is gradually superseding the spurious article usually sold under that name. The U. S. P. 1870 ordered a cerate made from it as a substitute for calamine cerate.

Off. Prep.—Liquor Zinci Chloridi, U. S., Br.

ZINCI CHLORIDUM. U. S., Br.

ZINC CHLORIDE

(zín'cí çhlō'rj-dūm)

 $\text{ZnCl}_2 = 135.26$

"It should contain, when anhydrous, not less than 99.5 percent. of pure Zinc Chloride, and

¹ "Take of Sulphate of Zinc, Carbonate of Sodium, each, *twelve troyounces*; Water, *eight pints*. Dissolve the salts separately, with the aid of heat, each in four pints of the Water. Then mix the solutions, and, having stirred the mixture set it by, that the powder may subside. Lastly, having poured off the supernatant liquid, wash the precipitate with hot water until the washings are nearly tasteless, and dry it with a gentle heat." U. S. 1870.

should be kept in small, glass-stoppered bottles." *U. S.* "Zinc Chloride, ZnCl_2 , is produced by the interaction of hydrochloric acid and zinc." *Br.*

Butter of Zinc; Chloruretum Zincicum; Chlorure de Zinc, *Fr. Cod.*; Zincum Chloratum, *P. G.*; Zinkchlorid, *Chlorzink, G.*; Cloruro zinico, *Sp.*

The British Pharmacopœia does not give a detailed process for making this salt; that of the *Br. Pharm.* 1885 follows.

"Take of Granulated Zinc one pound [avoirdupois]; Hydrochloric Acid forty-four fluidounces [Imperial measure]; Solution of Chlorine a sufficiency; Carbonate of Zinc half an ounce [av.], or a sufficiency; Distilled Water one pint [Imp. meas.]. Put the Zinc into a porcelain basin, add by degrees the Hydrochloric Acid previously mixed with the water, and aid the action by gently warming it on a sand-bath until gas is no longer evolved. Boil for half an hour, supplying the water lost by evaporation, and allow it to stand on a cool part of a sand-bath for twenty-four hours, stirring frequently. Test a few drops of the resulting liquid for iron or lead by adding excess of ammonia and then sulphhydrate of ammonium, when a black precipitate will be produced if iron or lead be present.

In the latter case filter the remainder of the product into a gallon bottle, and pour in the solution of chlorine by degrees, with frequent agitation, until the fluid acquires a permanent odor of chlorine. Add the carbonate of zinc, in small quantities at a time, and with renewed agitation, until a brown sediment appears, and the whole of the iron or lead is thus precipitated. Filter through paper into a porcelain basin, and evaporate until a portion of the liquid, withdrawn on the end of a glass rod and cooled, forms an opaque white solid. Pour it out now into proper moulds, and when the salt has solidified, but before it has cooled, place it in closely-stoppered bottles. If no iron or lead be present, filter and evaporate, etc., at once." *Br.* 1885.

In the *U. S.* process of 1870¹ the zinc chloride is obtained by evaporating the previously formed solution. The British first prepares the zinc chloride in solution, and in order to get rid of the iron uses chlorine, which combines with the iron to form ferric chloride, and, zinc carbonate being added, the zinc combines with the chlorine to increase the product of zinc chloride, while ferric oxide is deposited and carbon dioxide is set free. As this preparation is used chiefly as a caustic, it is melted and cast into moulds as the last step in the *Br.* process. In relation to this chloride, the reader is referred to a paper by B. J. Crew in *A. J. P.*, 1853. Rhigini prepares this chloride by double decomposition

between solutions of barium chloride and zinc sulphate. Barium sulphate is precipitated, and zinc chloride remains in solution, from which it is obtained in white flaky crystals by due evaporation. As zinc sulphate is obtainable in considerable quantities as a cheap by-product in the washing of pyrites and other sulphide ores containing zinc, as well as from the so-called "pickle waste" solutions from brass foundries, this is sometimes used as a commercial source for the manufacture of zinc chloride. Finely ground salt is added to the zinc sulphate solution, and the mixture chilled, when the sodium sulphate produced by the reaction crystallizes out, leaving zinc chloride in solution.

Properties.—It is officially described as "a white, granular powder, or porcelain-like masses, irregular, or moulded into pencils; odorless, of such intensely caustic properties as to make tasting dangerous, unless the salt be dissolved in much water; the dilute solution has an astringent, metallic taste. Very deliquescent. Soluble in about 0.4 part of water at 25° C. (77° F.), forming a clear solution, which, on protracted boiling, deposits a basic salt; very soluble in alcohol. When heated to 115° C. (239° F.), Zinc Chloride fuses to a clear liquid. At a higher temperature it is partly volatilized in dense, white fumes, and partly decomposed, leaving a residue of zinc oxide. Its aqueous solution reddens blue litmus paper. The aqueous solution of the salt (1 in 20) yields, with potassium ferrocyanide T.S., a white gelatinous precipitate, and with ammonium sulphide T.S. a pure white precipitate. Silver nitrate T.S. produces a white precipitate insoluble in nitric acid. The aqueous solution (1 in 20) should be clear, or at most only very slightly opalescent; and if it be mixed with an equal volume of alcohol, a single drop of hydrochloric acid should suffice to render 10 Cc. of the mixture perfectly clear (limit of oxychloride). The aqueous solution of the salt (1 in 20), to which 1 Cc. of diluted hydrochloric acid has been added, should not respond to the Time-Limit Test for arsenic, cadmium, lead, and copper (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted. If ammonium carbonate T.S. be added, in small portions, to the aqueous solution (1 in 20), the precipitate produced should be of a pure white color, and should redissolve completely in an excess of the reagent. The aqueous solution of the salt (1 in 20), after the addition of 1 Cc. of diluted hydrochloric acid, should not be rendered turbid by the addition of barium chloride T.S. (absence of sulphate). Dissolve 0.5 Gm. of Zinc Chloride in 200 Cc. of boiling distilled water, add about 5 drops of phenolphthalein T.S., and then sufficient sodium carbonate T.S., with constant stirring, to cause the solution to assume a permanent red color; transfer the resulting precipitate to a plain filter, wash it with boiling distilled water until all soluble matter

¹ "Take of Solution of Chloride of Zinc a convenient quantity. Evaporate the Solution to dryness in an evaporating dish, fuse the dry mass, pour the liquid on a flat stone, and when it has congealed, break the mass in pieces, and keep the fragments in a well-stopped bottle." *U. S.* 1870.

has been removed, then dissolve it in a sufficient quantity of nitric acid, evaporate the solution to dryness, and ignite the salt until it ceases to lose weight; the residue should weigh not less than 0.297 Gm." U. S. "In colorless opaque rods or tablets, very deliquescent and caustic; almost entirely soluble in water, alcohol (90 per cent.), and ether. It affords the reactions characteristic of zinc and of chlorides. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, or sulphates." Br.

When pure, it is wholly soluble in water, alcohol, and ether, but as prepared by the U. S. formula it contains some oxychloride, which is left undissolved by water. According to Lassaigne, commercial zinc chloride sometimes contains as much as 12 per cent. of zinc arsenate, which, being insoluble in solution of zinc chloride, will be left undissolved when the chloride is treated with water. By filtration, therefore, it may be entirely separated. It yields with ammonium and potassium hydroxide a white precipitate, soluble in those reagents when added in excess. It tends to form basic insoluble compounds, the so-called *oxychlorides*, of which Sorel's mass, $\text{Zn} \begin{Bmatrix} \text{OH} \\ \text{Cl} \end{Bmatrix}$, is an example.

These are used for cements and as a filling for teeth. The potassium and sodium carbonates also throw down white precipitates, which are not dissolved by an excess of the precipitants. Zinc chloride has a strong tendency to combine with organic bases, forming crystallizable compounds, as with strychnine, morphine, quinine, cinchonine, etc., in this respect resembling certain other metallic chlorides, as platinum, palladium, gold, and mercury chlorides. (*J. P. C.*, 4e sér., iii. 56.) When exposed to heat, zinc chloride first melts and then sublimes. It has been obtained in small deliquescent octahedrons of the formula $\text{ZnCl}_2 + \text{H}_2\text{O}$, by evaporating its hydrochloric acid solution to a syrup, and then adding a little concentrated hydrochloric acid. It consists of one atom of zinc and two of chlorine.¹

Uses.—Zinc chloride was introduced into medicine by Papenguth of St. Petersburg, and subsequently recommended by Hancke of Breslau, and Canquoin of Paris. Internally it has been given as an alterative and antispasmodic in *scrofula*, *epilepsy*, *chorea*, and other nervous diseases, but is of little or no value. Its chief use has been as an escharotic in *cancerous affections*. As a caustic it has the advantage of not causing constitutional disorder from absorption. Canquoin prepared zinc chloride as an escharotic by thoroughly and quickly mixing it with wheat flour and water into a paste of four different strengths, containing severally an ounce of the chloride incorporated with two, three, four, and five ounces of flour,

fifteen drops of water being added for every ounce of flour, or sufficient to form the paste.² According to the French Codex, *Caustique au Chlorure de Zinc*³ (*Canquoin's Paste*) is prepared by dissolving 8 parts of zinc chloride in 1 part of cold water and incorporating a mixture of 6 parts of flour with 2 parts of zinc oxide.

It is applied in cakes from a twelfth to a third of an inch in thickness, and produces an eschar more or less deep (from a line to an inch and a half), according to the thickness and strength of the paste, the length of the application, and the nature of the part acted on. Canquoin's strongest paste is applied to lardaceous and fibro-cartilaginous structures; the second, to *carcinomatous tumors*, and very painful *cancers* which have not much thickness; and the third, to *cancerous affections* in persons who have a dread of the use of the knife. These preparations, applied to the skin denuded of its cuticle by means of a blister, excite in a few minutes a sensation of heat, and afterwards violent burning pain. The eschar, which is white, thick, and very hard, falls off, with the aid of an emollient poultice, between the eighth and twelfth days. In all cases the caustic is to be reapplied, after the falling off of the eschar, until the whole morbid structure is destroyed. When the skin is unbroken, it is usual to destroy not merely the cuticle, but the true skin also, by means of acid mercuric nitrate, to the extent to which the chloride is desired to operate. This is applied spread on lint, and the dressing is covered with a portion of cotton wadding, to absorb any discharge and to preserve a uniform temperature. The surrounding skin should be protected from the caustic by a thickly-spread dressing of simple cerate.

Instead of flour, Alex. Ure of Glasgow, mixes the chloride with pure anhydrous calcium sulphate in impalpable powder. He states that this has the advantages of furnishing a porous medium from which the escharotic gradually exudes into the morbid structure, and of forming afterwards, by acquiring a firmer consistence, an impervious case for the eschar. Cock of Guy's Hospital, has imitated this mode of preparing the chloride, so as to form a caustic which may be limited in its action and does not run. It may be prepared as a caustic

² *Felix's Caustic Paste* (*L. L.*, vol. ii. 1887) is made according to the following formula: Starch, 37 grammes; Wheat Flour, 112 grammes; Mercuric Chloride, 1 gramme; Dry Zinc Chloride, 110 grammes; pure Iodol, 10 grammes; Croton Chloral, 10 grammes; Camphor Bromide, 10 grammes; Crystallized Carbolic Acid, 10 grammes; Distilled Water, sufficient to form a stiff homogeneous paste. The hand should be wetted when applying it. The paste is allowed to remain on from six to twenty-four hours, according to the amount of eschar it is desired to form.

³ P. Carles states that the official paste is too hygroscopic; he triturates in a mortar 10 grammes of fused zinc chloride with 2 grammes of 60 per cent. alcohol, and incorporates, with constant trituration, 15 grammes of wheat flour. This mass may be formed into cylinders of suitable size, and when once dry is but little affected by atmospheric humidity. (*L'Union Pharm.*)

¹ For the chemistry of its influence on camphor, see *Chem. News*, xx. 1869, p. 229.

seton by thickly covering a waxed cotton wick with Canquoin's caustic paste, and then rolling it out in the form of a cylinder, according to the plan of Ancrénis of Lyons. A thread is wound spirally round the cylinder to give it firmness.

In overdoses, zinc chloride acts as a corrosive poison, producing burning pain in the gullet and stomach, nausea and vomiting, cold sweats, depression of the pulse, and cramps of the legs. The antidotes are weak alkalies, or their carbonates, and, if these be not immediately at hand, soap.¹ Zinc chloride is not used internally.

Zinc chloride is a useful disinfectant, being inexpensive and comparatively non-poisonous.

ZINCI IODIDUM. U. S.

ZINC IODIDE

(zin'ci i-ôd'î-dûm)

$\text{ZnI}_2 = 316.70$

"It should contain, when anhydrous, not less than 98 percent. of pure Zinc Iodide, and should be kept in small, glass-stoppered bottles protected from light." U. S.

Zincum Iodatum; Iodure de Zinc, *Fr.*; Zinkjodid, *Jodzink*, *G.*

This iodide may be formed by digesting an excess of zinc, in small pieces, with iodine diffused in water. Combination takes place, and, by evaporation, a deliquescent, very soluble saline mass is obtained, having a metallic styptic taste, resembling that of zinc sulphate. It may also be obtained by heating in a flask a mixture of 20 parts of zinc and 170 of iodine, and subliming into a vial. Thus prepared, it is in the form of white needles. This salt is very liable to spontaneous decomposition.

Properties.—The U. S. Pharmacopœia (8th Rev.) describes it as "a white, granular powder; odorless, and having a sharp, saline and metallic taste. Very deliquescent, and, upon exposure to air and light, becoming brown from liberated iodine. Readily soluble in water, alcohol, or ether. When heated to about 446° C. (834.8° F.), the salt fuses to a colorless liquid, and at a higher temperature sublimes, forming quadratic needles, while a small part is decom-

posed and leaves a residue of zinc oxide. Its aqueous solution reddens blue litmus paper. An aqueous solution of the salt (1 in 20) yields a white gelatinous precipitate with potassium ferrocyanide T.S., and a pure white precipitate with ammonium sulphide T.S. With silver nitrate T.S. it yields a pale yellow precipitate, insoluble in ammonia water; with mercuric chloride T.S., a red precipitate, soluble in potassium iodide T.S. The aqueous solution of the salt (1 in 20), to which sufficient diluted hydrochloric acid has been added to insure a clear solution, should not respond to the Time-Limit Test for arsenic, cadmium, lead, and copper (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted. Another portion of the aqueous solution should not be rendered turbid upon the addition of barium chloride T.S. (absence of sulphate). If ammonium carbonate T.S. be added to the aqueous solution of the salt (1 in 20), a pure white precipitate will form, which should redissolve completely in an excess of the reagent. Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17). If 1 Gm. of Zinc Iodide be mixed with 5 Cc. of distilled water, and sufficient ammonia water be added to redissolve the precipitate formed, followed by a solution of 1.5 Gm. of silver nitrate in 10 Cc. of water, then, after shaking and filtering, the filtrate should not be rendered more than slightly turbid by the addition of an excess of nitric acid (limit of chloride). If 0.5 Gm. of dry Zinc Iodide be dissolved in 20 Cc. of water, and if 35 Cc. of tenth-normal silver nitrate V.S., 5 Cc. of nitric acid, and 3 Cc. of ferric ammonium sulphate T.S. be added, and the mixture well shaken, then the addition of not less than 3.4 Cc. nor more than 4 Cc. of tenth-normal potassium sulphocyanate V.S. should be required to give a permanent reddish-brown tint to the solution." U. S.

Uses.—Zinc iodide was proposed by Barlow as an alternative remedy in *chorea*, *scrofula*, and *hysteria* (*M. T. G.*, Nov. 1853), but has failed to come into general use. The best form of administration is in *syrup*, to protect it from change.² Zinc iodide has been used as an external application. A solution containing from one to two grains (0.065 to 0.13 Gm.) to the fluidounce (30 Cc.) of water has been used as an astringent injection in *gonorrhœa*.

Dose, one-half to two grains (0.032 to 0.13 Gm.).

² **Syrup of Zinc Iodide.**—A. B. Taylor prepared a *syrup of zinc iodide* by gently heating, in an evaporating dish, *twelve drachms and two scruples of iodine* and *an ounce of finely granulated zinc*, with *nine fluidounces of water*, until they unite, filtering the solution, while hot, on a *pound (av.) of sugar*, contained in a wide-mouthed bottle holding a little more than a pint, and adding, through the filter, sufficient water to make the whole measure a pint. This syrup is perfectly clear and colorless, is styptic to the taste, and contains a drachm of zinc iodide in each fluidounce. (*A. J. P.*, Jan. 1852, p. 33.) The dose of this syrup is from twenty to fifty minims (1.3 to 3.1 Cc.), sufficiently diluted with water, three times a day.

¹ **Solution of Zinc Hypochlorite.**—This may be prepared by the process of R. F. Fairthorne, as follows: "Take of Chlorinated Lime, 12 troyounces; Zinc Sulphate, 24 troyounces; Water, 12 pints. Dissolve the zinc sulphate in three pints of water. Triturate the chlorinated lime, a little at a time, with portions of the water added slowly, and mix thoroughly with the remainder of the water. Allow it to stand until the lime has subsided. Pour off the clear liquid. Transfer the sediment to a muslin strainer, and allow it to drain until sufficient liquid has passed to measure 8 pints with the decanted portion of the solution. Mix this with the solution of zinc sulphate, and, having set it aside for twelve hours, pour off the clear portion of the liquid and place the remaining portion on a piece of muslin to drain. Mix these liquids, and pour more water on the precipitate, if necessary, so as to make 11½ pints of the finished product." (*A. J. P.*, March, 1881.) This solution is recommended as having advantages over solution of chlorinated soda, in not being alkaline, and as combining astringent and antiseptic properties, and thus useful as an ingredient in gargles, injections, or lotions.

ZINCI OXIDUM. U. S., Br.

ZINC OXIDE

(zín'cí óx'í-düm)

ZnO = 80.78

"It should contain not less than 99.5 percent. of pure Zinc Oxide." U. S. "Zinc Oxide, ZnO, may be prepared by exposing zinc carbonate to a dull red heat, or from metallic zinc by combustion." Br.

Flores Zinci; Oxidum Zincicum; Oxyde de Zinc par vole sèche, Fleurs de Zinc, *Fr. Cod.*; Zincum Oxidatum, *P. G.*; Philosophenwolle, Zinkblumen, Zinkoxyd, *G.*; Oxido zincico, *Sp.*

Preparation.—The British Pharm. 1885 and the U. S. P. 1870¹ prepared the zinc oxide from the carbonate already formed. By referring to the article on Precipitated Zinc Carbonate, it will be found that it is obtained in the process from zinc sulphate, by the decomposing influence of sodium carbonate. Other methods of obtaining the zinc carbonate are by the mutual decomposition of the sodium chloride and carbonate and the ammonium sulphate and carbonate, but the former official plan is preferred. Lefort found it to furnish a carbonate which is washed with facility and is convertible by calcination into a pure oxide, readily reduced to an impalpable and very light powder. (*J. P. C.*, 3e sér., xi. 329.) It is, besides, more economical. The zinc carbonate, in whatever way obtained, is exposed to heat to drive off the carbon dioxide and water, in order to obtain the oxide. According to Mohr, a full red heat is not necessary, a temperature between 280° and 300° C. (536° and 572° F.) being sufficient. It is probable that an unnecessarily high heat injures the oxide as a therapeutic agent.

Zinc oxide may be obtained by the combustion of the metal, and in this way it was formerly prepared by the Dublin College. Zinc melts at 433° C. (801.4° F.), and immediately becomes covered with a film of gray oxide. When the temperature reaches nearly to redness, it takes fire and burns with an intense white light, generating the oxide in the form of very light and white flocculi, resembling carded wool, which quickly fill the crucible, and are in part driven into the atmosphere by the current of air. The late G. D. Midgely of London, several years ago, called attention to the production of zinc oxide by combustion, and gave a description of the apparatus by which he was enabled to prepare from one to two hundred-weight of the oxide at one operation. It consisted of a large muffle, heated to redness in a suitable furnace, and supplied with zinc from time to time as the combustion proceeded. The necessary draught of air was conveyed

from the muffle by a tube passing through the top of the furnace and terminating in a vessel of water, in which the portion of oxide carried up by the current was retained. The resulting oxide was freed from particles of metallic zinc by being passed through a sieve. Zinc oxide has been very largely produced from calamine by the so-called "furnace and bag" process, at Bethlehem, Pa., by the Lehigh Zinc Company. The process is as follows: The ore is first ground fine by a stone crusher, and then carefully mixed with coal known as "buckwheat," next in grade to "pea." It is then transferred to the furnaces, of which there are fifty-four, with 1390 feet of grate-surface. Within these the mixed coal and ore are reduced by the direct action of heat and the cold blast upon a furnace bed having a multiplicity of small holes, each producing the reducing flame of the blow-pipe. The zinc oxide rises, and passes through a huge combustion flue to a large circular tower, 50 feet high, in which the oxide and ashes separate. The ashes being heavier than the oxide, the velocity of the fans which impel the product forward lifts the oxide to the top, and the ashes drop to the bottom. The oxide is forced onward through a cooling-room, size 80 by 40 feet, and heated to from 400° to 700° F. Thence the oxide is blown through large flues into the "bag" room. This is in a large building, devoid of furniture, except bags of muslin, 45 feet long, in which the oxide is deposited. It is now very white, and, after being kiln-dried and bolted, is by heavy pressure reduced in bulk and barrelled, ready for shipment. The production of zinc oxide for pigment purposes has assumed large proportions, amounting in 1904 to 63,363 short tons, valued at \$4,808,482, and in 1905 to 65,403 short tons, valued at \$5,232,240.

Properties.—The official zinc oxide is described in the U. S. Pharmacopœia as "a very fine, amorphous, white or yellowish-white powder, free from gritty particles, without odor or taste; it gradually absorbs carbon dioxide from the air. Insoluble in water or alcohol. Completely soluble without effervescence, in diluted acids; also in ammonia water, and in ammonium carbonate T.S. When heated, it assumes a yellow color, which disappears on cooling. If a small portion of Zinc Oxide be moistened with a drop of cobaltous nitrate T.S., and heated before the blow-pipe, it will assume a vivid green color. For making tests of identity and purity, digest 1 Gm. of Zinc Oxide, with occasional agitation, in a mixture of 10 Cc. of diluted hydrochloric acid and 10 Cc. of water until saturated; then remove the undissolved Zinc Oxide by filtration. In a portion of the filtrate a white gelatinous precipitate is produced by potassium ferrocyanide T.S., and a pure white precipitate by ammonium sulphide T.S. Another portion of the filtrate, acidulated with hydrochloric acid, should not respond to the Time-Limit Test for arsenic, cadmium, lead, and copper (see PART III, Test

¹ "Take of Precipitated Carbonate of Zinc twelve troyounces. Expose it, in a shallow vessel, to a low red heat until the water and carbonic acid are wholly expelled." U. S. 1870.

No. 121); in applying this test the addition of ammonia water should be omitted. Another portion of the filtrate should yield, upon the gradual addition of ammonium carbonate T.S., a pure white precipitate, which should almost completely redissolve in an excess of the reagent. If 1 Gm. of Zinc Oxide be placed in a flask with 10 Cc. of boiling water, and 2 drops of phenolphthalein T.S. be added, not more than 1 Cc. of tenth-normal hydrochloric acid V.S. should be required to discharge the red color (limit of *alkali*). If 1 Gm. of Zinc Oxide be dissolved in a sufficient quantity of diluted nitric acid, the solution should remain clear upon the addition of silver nitrate T.S. (absence of *chloride*), and not become more than slightly turbid upon the addition of barium chloride T.S. (limit of *sulphate*). If 1 Gm. of freshly ignited Zinc Oxide be digested with 30 Cc. of normal hydrochloric acid V.S. until solution is complete, and 2 drops of methyl-orange T.S. be added, not more than 5.4 Cc. of normal potassium hydroxide V.S. should be required for neutralization (each Cc. of normal hydrochloric acid consumed corresponding to about 4 percent. of zinc oxide). The normal potassium hydroxide V.S. should be added slowly with constant stirring, waiting until the precipitated zinc hydroxide has redissolved before adding further portions of the reagent." *U. S.* "Prepared from the carbonate it is a soft, nearly white, tasteless and inodorous powder, becoming pale yellow when heated; prepared by combustion it is white. It affords the reactions characteristic of zinc. It should be entirely soluble when rubbed, and, if necessary, warmed, with *solution of ammonia* mixed with *strong solution of ammonia* (absence of metallic zinc). It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, carbonates, chlorides, or sulphates." *Br.* As obtained by combustion, it is perfectly white. It dissolves in solution of potassium and sodium hydroxides, but not in their carbonates. Being anhydrous, it is insoluble in ammonia, but the impure oxide found in commerce, being generally hydrated, is soluble in that alkali. At a low white heat it fuses, and at full whiteness sublimes. When prepared by combustion it was formerly called *pompholix*, *nihil album*, *lana philosophica*, and *flowers of zinc*. Prepared by the old official process,—namely, by precipitating zinc sulphate with ammonia,—it contains the subsulphate, the acid of which may be detected by dissolving the oxide in nitric acid and precipitating by barium nitrate. Sometimes it is obtained by precipitating zinc chloride with ammonia, in which case the oxide contains subchloride, easily detected by silver nitrate. If it contains white lead or chalk, it will not be entirely soluble in diluted sulphuric acid, but an insoluble lead or calcium sulphate will be left. If iron be present, brownish-red flocks of ferric oxide will remain

undissolved when the hydrochloric acid solution of the zinc oxide is treated with ammonia in excess.

The powder sold in commerce as zinc oxide is often very impure. Sometimes the carbonate is substituted for it, showing that the exposure to a red heat has been omitted. In this case the preparation will effervesce with acids. Some samples contain a large proportion of subsulphate, showing that the discarded but productive process of precipitating the solution of zinc sulphate by ammonia has been employed. Again, other samples contain oxychloride. These impure oxides are pointed out by Redwood of London, as occurring in the English market, and no doubt are sold in the United States. (See *P. J.*, 1855, p. 301.) A sample of commercial zinc oxide is noticed in *N. R.*, Aug. 1878, which proved to be powdered gypsum. Unfortunately, a white oxide is preferred by purchasers, though whiteness is generally a sign of impurity; the yellowish-white official oxide should be exclusively used by pharmacists.

Uses.—This oxide is antispasmodic and astringent. It has been given in *chorea*, *epilepsy*, *whooping cough*, and *gastric and intestinal catarrhs*. Externally it is employed as an exsiccant to excoriated surfaces and in various *skin diseases*, sometimes by sprinkling it on the affected part, but generally in the form of ointment. (See *Unguentum Zinci Oxidi*.) It has also been used in *gonorrhœa*. (*N. R.*, July, 1874.) As a cosmetic it has the great advantage over the preparations of lead of not being poisonous.

Zinc oxide, prepared by combustion, called commercial zinc oxide, is extensively used in painting as a substitute for white lead, over which it has the advantage of not being discolored by hydrogen sulphide. It is stated that it has greater covering power as a color than white lead, 10 parts being equal to 13 of white lead. It is, however, dearer, so that the pure oxide has not replaced white lead. The oxide thus prepared, even though pure, should not be substituted for the official, as it has not the smoothness and freedom from gritty particles possessed by the latter. There is an English preparation known as *Griffith's zinc white*, or *lithophone*, made by precipitating zinc sulphate by barium sulphide; it is, therefore, a mixture of zinc sulphide and barium sulphate. If this be roasted in a current of superheated steam the zinc sulphide will be converted into zinc oxide. This process has been patented in Germany by Meissner. (*Wagner's Chem. Technol.*, 11th ed., p. 159.) It has, moreover, the merit of not producing injurious effects on the workmen at all comparable to those caused by white lead. It is, indeed, usually considered innocuous; but a case of chronic poisoning by it has been reported by Botkin. (*B. F. M. R.*, ii. 1873.)

Dose, two to five grains (0.13 to 0.32 Gm.), preferably in pill form.

Off. Prep.—*Unguentum Zinci Oxidi*, *U. S.* (*Br.*).

ZINCI PHENOLSULPHONAS. U. S. (Br.)**ZINC PHENOLSULPHONATE** [Zinc Sulphocarbolate]

(zín'cí phē-nól-sul'phō-nās)

"It should contain, in uneffloresced crystals, not less than 99.5 percent. of pure Zinc Paraphenolsulphonate [$(\text{C}_6\text{H}_4(\text{OH})\text{SO}_3)_2\text{Zn}$ 1:4 + $8\text{H}_2\text{O}$], and should be kept in small, well-stoppered bottles." *U. S.* "Zinc Sulphocarbolate, or zinc phenol-para-sulphonate, $\text{Zn}(\text{OH}.\text{C}_6\text{H}_4\text{SO}_3)_2.\text{H}_2\text{O}$, may be obtained by heating a mixture of phenol and sulphuric acid, and saturating the product with zinc oxide." *Br.*

Zinc Sulphocarbolat, Br.: Zincum Sulphophenolicum; **Zinc Paraphenolsulphonate;** Sulphophénate de Zinc, *Fr.;* Phenolsulfosaures Zink, Sulfocarbol-saures Zink, *Gr.*

Properties.—It is officially described as in "colorless, transparent, rhombic prisms or tabular crystals; odorless, and having an astringent, metallic taste. Exposed to the air the salt effloresces, and upon exposure to light and air may become slightly pink. Soluble in 1.7 parts of water or alcohol at 25° C. (77° F.), and in 0.3 part of boiling water, and 0.56 part of boiling alcohol. When heated to 100° C. (212° F.), the salt loses 6 molecules of water of crystallization, and it loses the remainder at 125° C. (257° F.). At a higher temperature it chars, emitting inflammable vapors having the odor of phenol, and finally leaves a residue amounting to about 14.6 percent. of the original weight. Its aqueous solution reddens blue litmus paper. A dilute solution of the salt (1 in 100) is colored pale violet by ferric chloride T.S. The aqueous solution of the salt (1 in 20) yields, with potassium ferrocyanide T.S., a white gelatinous precipitate, and, with ammonium sulphide T.S., a pure white precipitate. Ammonium carbonate T.S., or potassium hydroxide T.S., when added in small portions to the aqueous solution of the salt (1 in 20), produces a precipitate of a pure white color, which dissolves completely upon the addition of an excess of the reagent. The aqueous solution of the salt (1 in 20), to which 1 Cc. of diluted hydrochloric acid has been added, should not respond to the Time-Limit Test for arsenic, cadmium, lead, and copper (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted. The aqueous solution of the salt (1 in 20) should not become turbid upon the addition of barium chloride T.S. (absence of sulphate), nor silver nitrate T.S. (absence of chloride). Five Cc. of the aqueous solution of the salt (1 in 10) should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17)." *U. S.* "Colorless, transparent, tabular, efflorescent crystals; soluble in 2.5 parts of alcohol (90 per cent.), and in 2 parts of water. The aqueous solution is colored violet by test-solution of ferric chloride, and affords a white precipitate with solution of ammonium hydro-sulphide. It should yield no characteristic

reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium, magnesium, sodium, potassium, ammonium, acetates, or chlorides, and only the slightest reactions with the tests for sulphates." *Br.*

Uses.—Zinc phenolsulphonate has been employed as an antiseptic astringent stimulant to indolent or foul ulcers, and in subacute inflammations of the mucous membrane. The solutions used may be a little stronger than those of zinc sulphate employed for similar purposes. It has also been used as an intestinal antiseptic.

Dose, one to three grains (0.065 to 0.2 Gm.).

ZINCI STEARAS. U. S.**ZINC STEARATE**

(zín'cí stē'ar-ās)

Stéarate de Zinc, Fr.; Zinkstearat, Stearinsäures Zinkoxyd, Talgsäures Zinkoxyd, *Gr.*

Preparation.—Zinc stearate may be made by Hallberg's formula as follows: Castile Soap, granular and dried, *two hundred grammes*; zinc acetate, *seventy-five grammes*; distilled water, *a sufficient quantity*. Add the soap to 3000 Cc. of hot distilled water; stir until dissolved; strain the liquid, and set it aside until cold. Dissolve the zinc acetate in 5000 Cc. of cold distilled water, and filter the solution into the soap solution, stirring constantly. Draw off the liquid, and wash the precipitate thoroughly several times with water; collect the magma on a muslin strainer without expression, and let it dry by exposure to air, without heat, protecting it against dust. Zinc stearate may also be made by mixing a solution of potassium stearate with one of zinc acetate, washing, and then drying the precipitate. For a process for zinc oleostearate by F. E. Niece in which he uses oleic and stearic acids and solution of zinc acetate, see *Proc. Penna. Pharm. Assoc.*, 1902, 135. Zinc stearate differs from the oleate of zinc of the *U. S. P.* 1890; the latter was a soft ointment-like solid.¹

Properties.—It is officially described as "a very fine, white powder, tasteless, and having a very faint odor, resembling that of fat. Zinc Stearate contains a small but varying proportion of zinc palmitate. Insoluble in water, alcohol, or ether. When heated, the salt fuses. At a higher temperature it is decomposed, giving off inflammable vapors and the odor of burning fat, and finally leaves about 15.5 per-

¹ *Oleatum Zinci, U. S. Oleate of Zinc.*—"Zinc Oxide, *fifty grammes* [or 1 ounce av., 334 grains]; Oleic Acid, *nine hundred and fifty grammes* [or 33 ounces av., 223 grains], to make *one thousand grammes* [or 35 ounces av., 120 grains]. Introduce the Oleic Acid into a capacious capsule, and gradually add to it the Zinc Oxide by sifting it upon the surface of the Acid, and incorporate it by continuous stirring. Set the mixture aside for a few hours, and then heat it on a water-bath, frequently stirring, until the Oxide is dissolved." *U. S.* 1890.

This oleate was found for the first time in the *U. S. Pharmacopœia* of 1890. It was official in the British *Pharmacopœia* of 1885. (See *Unguentum Zinci Oleatis*.)

cent. of residue, which consists chiefly of zinc oxide. The salt should have a neutral reaction to moistened litmus paper. If 0.5 Gm. of Zinc Stearate be heated with a mixture of 9.5 Cc. of distilled water and 0.5 Cc. of hydrochloric acid, stearic acid will be liberated and float as an oily layer on the surface of the liquid. If, after filtering this liquid through a small wetted filter, all of the zinc be precipitated by ammonium sulphide T.S., the filtrate should leave no fixed residue on evaporation (absence of *alkalies, alkali earths*, etc.). If 0.5 Gm. of Zinc Stearate be heated with a mixture of 9.5 Cc. of distilled water and 0.5 Cc. of nitric acid, and filtered, the filtrate should not become more than slightly turbid upon the addition of silver nitrate T.S. (absence of more than traces of *chlorides*). If 1 Gm. of Zinc Stearate be boiled with 50 Cc. of distilled water containing 2 Cc. of nitric acid, and filtered through a wetted filter, after thoroughly washing the precipitate with boiling water, the filtrate and washings, when evaporated to dryness and ignited, should leave a residue weighing not less than 0.14 Gm., and not more than 0.16 Gm." *U. S.*

Uses.—Zinc stearate is employed in *eczema, acne* and other cutaneous diseases, in the form of powder, or made into an ointment.

Off. Prep.—Unguentum Zinci Stearatis, *U. S.*

ZINCI SULPHAS. U. S., Br.

ZINC SULPHATE

(zīn'ci sul'phās)

"It should contain, in uneffloresced crystals, not less than 99.5 percent. of pure Zinc Sulphate [$\text{SO}_2.\text{O}_2\text{Zn} + 7\text{H}_2\text{O}$], and should be kept in well-stoppered bottles." *U. S.* "Zinc Sulphate, $\text{ZnSO}_4.7\text{H}_2\text{O}$, is formed by the interaction of diluted sulphuric acid and zinc." *Br.*

Sulfas Zincicus, Vitriolum Album; White Vitriol; Sulfate de Zinc officinal, *Fr. Cod.*; Zincum Sulfuricum, *P. G.*; Zinksulfat, Schwefelsaures Zinkoxyd, Weisses Vitriol, Galltzenstein, *G.*; Solfato di zinco, *It.*; Sulfato zinco, *Sp.*

The Pharmacopœias no longer give detailed processes for preparing this salt. The *Br. Ph.* 1885 process will be found in the foot-note.¹

¹ "Take of Granulated Zinc sixteen ounces [avoirdupois]; Sulphuric Acid twelve fluid ounces [Imperial measure]; Distilled Water four pints [Imp. meas.]; Solution of Chlorine a sufficiency; Carbonate of Zinc half an ounce [av.], or a sufficiency. Pour the sulphuric acid previously mixed with the water on the zinc contained in a porcelain basin, and, when effervescence has nearly ceased, aid the action by heat. Test a few drops of the resulting liquid for iron by adding excess of ammonia and then sulphhydrate of ammonium, when a black precipitate will be produced if iron be present. In the latter case filter the remainder of the fluid into a gallon bottle, and add gradually with constant agitation the solution of chlorine until the fluid acquires a permanent odor of chlorine. Add now with continued agitation the carbonate of zinc until a brown precipitate appears and the whole of the iron is thus precipitated. Let the precipitate subside, filter the solution, evaporate till a pellicle forms on the surface, and set aside to crystallize. Dry the crystals by exposure to the air on filtering paper placed on porous tiles. More

Strong sulphuric acid is but slightly acted upon by zinc, some hydrogen sulphide being evolved by the reduction of the acid; but when it is *diluted*, the acid is instantly decomposed, and, while hydrogen escapes with rapid effervescence, it is replaced by the zinc with the production of zinc sulphate. From this it will be perceived that *hydrogen* is a collateral product of the process. The proportion of the zinc to the strong acid in the process is as 4 to 5.53. The molecular weights give the ratio of 4 to 6 almost exactly,—which indicates that the metal is somewhat in excess. If the materials are mixed at once, without any precaution, the effervescence of hydrogen is apt to be excessive, and to cause the overflowing of the liquid. This may be avoided by commencing the solution of zinc with a very dilute acid, which, as the action slackens, is made by degrees stronger and stronger by the addition, at intervals, of small portions of fresh acid. As the zinc of commerce generally contains iron, this would contaminate the product, unless precautions were taken to prevent it. Hence the addition of chlorine, which reacts with ferrous sulphate to form ferric sulphate and ferric chloride, which, upon the addition of zinc carbonate, yield sulphuric acid and chlorine to the zinc, ferric oxide being deposited and carbon dioxide set free. The former is separated by filtration, the latter escapes during the evaporation, the additional zinc sulphate crystallizes with that first formed, and the zinc chloride remains in the mother waters.

Preparation on the Large Scale.—Impure zinc sulphate, as it occurs in commerce, is called *white vitriol*. It is manufactured by roasting *blende* (native zinc sulphide) in a reverberatory furnace. This mineral, besides zinc sulphide, contains small quantities of iron, copper, and lead sulphides, and by roasting is converted, in consequence of the oxidation of its constituents, into zinc sulphate, mixed with iron, copper, and lead sulphates. The roasted matter is then lixiviated, and the solution obtained, after having been allowed to settle, is concentrated by evaporation, so that, on cooling, it may concrete into a white crystalline mass. In this state it always contains ferrous sulphate, and sometimes a small proportion of copper sulphate. It may be purified from these metals by dissolving it in water and boiling the solution with zinc oxide, which converts the iron and copper sulphates, by precipitating their bases, into zinc sulphate. The purified solution is then decanted or filtered, and, after due evaporation, allowed to crystallize. It has generally been proposed to purify the white vitriol of commerce by digesting its solution with metallic zinc, under the impression that this is capable of precipitating all the foreign metals; but, according to Berzelius, though it will precipitate copper readily, it has no action on iron.

crystals may be obtained by again evaporating the mother-liquor. If no iron be present, filter, and evaporate, etc., at once." *Br.* 1885.

F. Stolba recommends a process which has been used successfully for the purification of zinc sulphate by the use of zinc carbonate and zinc permanganate. (See *A. J. P.*, 1877, p. 72.)

Properties.—Zinc sulphate is in "colorless, transparent, rhombic crystals, or a granular, crystalline powder, without odor, and having an astringent, metallic taste. Efflorescent in dry air. Completely soluble in 0.53 part of water at 25° C. (77° F.), and in 0.2 part of boiling water; soluble in about 3 parts of glycerin; insoluble in alcohol. When rapidly heated, the salt melts. At a higher temperature it is partly decomposed, losing both water and sulphuric acid. When very gradually heated to 50° C. (122° F.), it loses 5 molecules of its water of crystallization (31.2 percent.) without melting. At 100° C. (212° F.) a sixth molecule is lost, while the last is removed, with decomposition of the salt, at a temperature of about 240° C. (464° F.). Its aqueous solution shows an acid reaction with blue litmus paper. The aqueous solution of the salt (1 in 20) yields a white gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S., and with barium chloride T.S. If a small portion of the salt be moistened with a drop of cobaltous nitrate T.S., and heated before the blow-pipe, it will assume a vivid green color. The aqueous solution of Zinc Sulphate (1 in 20), after being acidulated with hydrochloric acid, should not respond to the Time-Limit Test for *arsenic, cadmium, lead, and copper* (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted. The aqueous solution should yield, with ammonium carbonate T.S., a white precipitate, which should redissolve completely in an excess of the reagent. The aqueous solution (1 in 20) should not be rendered more than slightly turbid by silver nitrate T.S. (limit of *chloride*). If 1 Gm. of Zinc Sulphate, in small fragments, be agitated for some time with 10 Cc. of alcohol, the filtrate should not redden moistened blue litmus paper (absence of *free acid*)." *U. S.* "Colorless transparent prismatic crystals with a strong metallic styptic taste. Soluble in less than an equal weight of cold water. It affords the reactions characteristic of zinc and of sulphates. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, aluminium, calcium, magnesium, sodium, potassium, ammonium, or acetates, and only the slightest reactions with the tests for iron or chlorides." *Br.* Its crystals have considerable resemblance to those of magnesium sulphate. It effloresces slightly in dry air, and, though neutral in composition, reddens vegetable blues. When heated it dissolves in its water of crystallization, which gradually evaporates, and by a prolonged ignition the whole of the acid is expelled, and the zinc oxide left. The alkaline carbonates precipitate the metal in the state of white carbonate. Pure zinc sulphate is precipitated white by potassium ferro-

cyanide and ammonium sulphhydrate. What is thrown down by barium chloride or lead acetate (barium sulphate or lead sulphate) is not dissolved by nitric acid. If copper be present, ammonia will produce a blue tinge; if iron, the potassium ferrocyanide will cause a bluish-white precipitate instead of a white one, and tincture of galls a purple color. Cadmium and arsenic may be detected by acidulating the solution with sulphuric acid and passing a stream of hydrogen sulphide through it, when, if either of these metals be present, it will be thrown down as a yellow sulphide. Zinc sulphate is incompatible with alkalies and alkaline carbonates, sulphides, lime water, the soluble lead salts, and astringent infusions.

The impure commercial variety of zinc sulphate is in the form of irregular white masses having some resemblance to lump sugar. The lumps usually exhibit, here and there on the surface, yellow stains, produced by ferric oxide. It is less soluble than the pure salt, on account of its containing less water of crystallization.

Composition.—Crystallized zinc sulphate consists of one sulphuric acid group, SO_4 , one atom of zinc, and seven molecules of water. The *white vitriol* of commerce contains but three molecules of water.

Uses.—This salt is tonic, astringent, and, in large doses, a prompt emetic, producing very little depression, and much used when it is desired simply to evacuate the stomach. In *gastric catarrh* it is sometimes useful, in the dose of one-fourth of a grain (0.016 Gm.) before meals, in pill. It was formerly used in *night sweats, epilepsy, chorea*, and other nervous diseases, but has now entirely passed out of vogue as a remedy in such affections. As an astringent it is chiefly employed externally. Its solution constitutes a good styptic to bleeding surfaces, and is frequently resorted to as an injection in *fluor albus* and *gonorrhœa*, and as a collyrium in *ophthalmia*, also as a stimulant application to *ulcers* both of the mucous membrane and of the skin. Simpson of Edinburgh, employed dried zinc sulphate in the form of powder, paste, or ointment, as a powerful, rapid, manageable, and safe caustic in indurated inflammatory ulcers of the cervix uteri; in *lupus*; in *ulcerous forms of skin diseases*; and in removing *urethral caruncles, condylomata, warty excrescences*, etc. The dried salt should be finely levigated. The caustic paste is made by incorporating an ounce of the powder with a drachm of glycerin; and the caustic ointment, by thoroughly mixing the same quantity of the powder with two drachms of lard. (See *Am. J. M. S.*, April, 1857, p. 485.)

Zinc sulphate, in an overdose, acts as an irritant poison. Besides vomiting and incessant retching, it produces anxiety, distressing restlessness, and extreme prostration. Few cases are on record of fatal poisoning by this salt, the patient being generally relieved by

its prompt expulsion in vomiting. Death is said to have been caused, however, by an ounce and a half. The treatment consists in the free administration of bland drinks, the use of opium to allay irritation, and the employment of the usual antiphlogistic remedies should symptoms of inflammation arise.

Dose, from one-fourth to one-half grain (0.016 to 0.032 Gm.); as an emetic, from ten to thirty grains (0.65 to 2.0 Gm.). When used as a collyrium, an injection, or a gargle, or as a wash for indolent ulcers, from one to three grains (0.065 to 0.2 Gm.) or more may be dissolved in a fluidounce (30 Cc.) of water. For medicinal purposes the crystallized salt only should be used.

Off. Prep.—Unguentum Zinci Oleatis, Br.

ZINCI VALERAS. U. S. (Br.)

ZINC VALERATE

[Zinci Valerianas, Pharm. 1890, Zinc Valerianate]

(zín'cí vāl'ē-rās)

"It should contain not less than 99 percent. of pure Zinc Valerate [(C₅H₉COO)₂Zn + 2H₂O], and should be kept in small, well-stoppered bottles." *U. S.* "Zinc Valerianate, or zinc iso-valerianate, Zn(C₅H₉O₂)₂, may be prepared by saturating iso-valerianic acid with zinc carbonate, or by the interaction of zinc sulphate and sodium iso-valerianate." *Br.*

Zinci Valerianas, Br.; Zincum Valerianicum; Valerianas Zincicus; Valerianate de Zinc, *Fr. Cod.*; Valérate de Zinc, *Fr.*; Zincvalerianat, *Baldrian-saures Zinkoxyd, G.*; Valerianato zincico, *Sp.*

Zinc valerianate was formerly included among the preparations of the U. S. Pharmacopœia, but at the revision of 1880 no process was inserted. The British Pharmacopœia no longer gives a formula for its preparation; for former formulas see foot-note.¹

¹ "Take of Valerianate of Soda two troyounces and a half; Sulphate of Zinc two troyounces and four hundred and twenty grains; Distilled Water a sufficient quantity. Dissolve the salts separately, each in twenty fluidounces of Distilled Water, and, having heated the solutions to 212° F., Decant the mother-water from the crystals, and put them upon a filter in a funnel to drain. Mix the mother-water and the drainings, evaporate at a heat not exceeding 200° F. to four fluidounces, and again set aside to crystallize. Add the crystals, thus obtained, to those in the funnel, wash the whole with a little Distilled Water, and, having removed them with the filter, spread them on bibulous paper, and dry them with a heat not exceeding 200° F." *U. S.* 1870.

"Take of Sulphate of Zinc five ounces and a half [avoirduois]; Valerianate of Sodium five ounces [av.]; Distilled Water a sufficiency. Dissolve the Sulphate of Zinc and the Valerianate of Sodium, each, in two pints [Imperial measure] of the Water; heat both solutions to near the boiling point, mix them, cool, and skim off the crystals which are produced. Evaporate the mother-liquor at a heat not exceeding 200° F. till it is reduced to four [fluid] ounces; cool again, remove the crystals which have formed, and add them to those which have been already obtained. Drain the crystals on a paper filter, and wash them with a small quantity of cold Distilled Water, till the washings give but a very

Properties.—This salt is in "white, pearly scales, having the odor of valeric acid, and a sweetish, astringent, and metallic taste. On exposure to the air, it slowly loses valeric acid. Soluble in about 50 parts of water, and in about 35 parts of alcohol at 25° C. (77° F.); somewhat more soluble in absolute alcohol. Boiling renders the aqueous solution turbid from loss of acid and formation of a basic salt. When heated, the salt melts. At a higher temperature it is decomposed, giving off inflammable vapors, and finally leaving a residue of zinc oxide. Its aqueous solution reddens blue litmus paper. If 0.5 Gm. of Zinc Valerate be dissolved in a mixture of 0.5 Cc. of hydrochloric acid and 9 Cc. of water, the valeric (isovaleric) acid will be liberated and float as an oily layer on the surface of the liquid. After filtering through a small wetted filter, the clear solution should not respond to the Time-Limit Test for arsenic, cadmium, lead, and copper (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted. If 0.5 Gm. of Zinc Valerate be dissolved in a mixture of 0.5 Cc. of nitric acid and 4.5 Cc. of distilled water, and the mixture filtered through a small wetted filter, the filtrate should remain clear upon the addition of either barium chloride T.S. (absence of sulphate) or silver nitrate T.S. (absence of chloride). Zinc Valerate should dissolve without residue in ammonium carbonate T.S. If 0.5 Gm. of Zinc Valerate be triturated with 3 Cc. of water, and 0.2 Cc. of ferric chloride T.S. added, the filtrate should not show a red color (absence of acetate). If a concentrated solution of copper acetate in water be added to a concentrated aqueous solution of Zinc Valerate, the mixture should remain perfectly clear (absence of butyrate). If 0.5 Gm. of Zinc Valerate be heated with a mixture of 9.5 Cc. of distilled water and 0.5 Cc. of hydrochloric acid and filtered, the filtrate should not respond to the Modified Gutzeit's Test for arsenic (see PART III, Test No. 17)." *U. S.* "In white pearly tabular crystals, with a disagreeable odor, and a metallic taste; very slightly soluble in cold water or in ether, soluble in hot water and alcohol (90 per cent.). On heating to redness, after moistening with a small quantity of nitric acid, it should yield not less than 26 nor more than 30 per cent. of zinc oxide. It should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, iron, aluminium, calcium,

feeble precipitate with chloride of barium. Let them now be again drained, and dried on filtering paper at ordinary temperatures." *Br.*

These formulas are essentially the same as the formula of the late Dublin Pharmacopœia. In the formation of the salt a double decomposition takes place between the reacting salts, resulting in the production of zinc valerianate and sodium sulphate. Upon mixing the hot solutions, crystals of the sparingly soluble zinc valerianate form on the surface of the liquid, and during the progress of its concentration to one-tenth, more of them are successively produced. These are then washed with cold distilled water to separate adhering sodium sulphate, drained on a filter, and dried.

magnesium, sodium, potassium, ammonium, acetates, or carbonates, and only the slightest reactions with the tests for chlorides or sulphates. When heated with *diluted sulphuric acid* it gives a distillate which, when mixed with *solution of copper acetate*, does not immediately affect the transparency of the liquid, but forms after a little time oily drops, which gradually pass into a bluish-white crystalline deposit (absence of butyrates)." *Br.* The salt, as obtained by the British 1885 and U. S. P. 1870 formulas, contained one molecule of water; but when formed by saturating zinc carbonate, made into a paste with water, with valeric acid, it contains six molecules of water, and when dried at 50° C. (122° F.), perfectly resembles the official salt. (Wittstein.) Other authorities (Flückiger, *Pharm. Chem.*, and Roscoe and Schorlemmer's *Chem.*, vol. iii. part i.) give the formula of the stable crystallized salt as $\text{Zn}(\text{C}_5\text{H}_9\text{O}_2)_2 + 2\text{H}_2\text{O}$. Zinc acetate impregnated with oil of valerian has been substituted for this salt; but at present, from the relative costliness of the oil, there is no inducement to this fraud. Zinc butyrate has been sold in Paris for the valeriate, and is so like it as not to be distinguished by its physical properties. The two salts, however, may be differentiated by adding a concentrated solution of the acid of the suspected salt obtained by distillation with sulphuric acid, to a concentrated solution of copper acetate. If the acid be the butyric, its addition to the solution of the acetate will disturb the transparency of the latter, by the formation of a bluish-white precipitate; if it be the valeric, no change will be produced. (Larocque and Huraut, *J. P. C.*, 3e sér., ix. 430.)

Uses.—Zinc valerate was proposed as a remedy, on theoretical grounds, by Prince Louis-Lucien Bonaparte. Upon trial it was found to possess antispasmodic properties, and has been used in *diabetes insipidus*. By some of the Italian physicians it has been extolled as a remedy in *neuralgia*. F. Devay of Lyons, found it useful in *epilepsy*, and in the nervous affections which accompany *chlorosis*.

Dose, one to two grains (0.065 to 0.13 Gm.), repeated several times a day, and given in the form of pill.

ZINCUM. U. S., Br.

ZINC

(zīn'cūm)

Zn = 64.9

"It should contain not less than 99 percent. of pure metallic Zinc." *U. S.* "The laminated or granulated metal." *Br.*

Spectrum: Zinc pur. *Fr. Od.*; Speltre, Zinc, *Fr.*; Zink, *G.*; Zinco, *It.*; Zinc, *Sp.*

Zinc occurs native in two principal states, as a sulphide, called *blende*, and as a carbonate or silicate, to which the name of *calamine* is

applied indiscriminately. In this country there are two additional ores that are worked for zinc. Both occur at Franklin and Mine Hill, New Jersey, and are characteristic of those localities. They are the native oxide, called *red oxide* or *zincite*, and a mixture of zinc oxide with manganese and iron oxide, known as *franklinite*. Zinc has been detected in the vegetable kingdom in a peculiar violet, *Viola calamina*, growing on the calamine hills of Rhenish Prussia. It is largely produced in Belgium, Germany, and this country, the chief American localities being the southwestern section of Missouri, together with the neighboring counties of Kansas, the New Jersey localities before mentioned, Lehigh County, Pennsylvania, Virginia, and Wisconsin. The metal is extracted generally from blende or calamine. This is roasted and mixed with charcoal powder, and the mixture heated in iron cylinders placed horizontally over a furnace. When the reduction of the zinc commences, iron receivers are adapted to the opening of the cylinder to condense the volatilized metal. The metal is then melted and run into moulds, and forms *spelter*, or the zinc of commerce. In this state it contains iron, and traces of lead, cadmium, arsenic, copper, sulphur, and charcoal. To purify it from these substances, it must be subjected to a second distillation in a crucible, furnished with a tube passing through its bottom and open at both ends, its upper extremity reaching a little more than half-way up the interior of the crucible, and its lower end terminating above a vessel of water. The impure zinc being placed in the crucible, the cover luted on, and the fire applied, the pure zinc is volatilized, and, passing down the tube by a descending distillation, condenses in the water below. In the arts zinc is purified sufficiently for commercial purposes without volatilization.

The production of spelter in the United States for the year 1904 amounted to 186,704 tons, and for 1905 to 203,849 tons. The world's production for the same years amounted to 693,022 tons and 727,141 tons respectively. The percentage of production for the United States in these years was 26.9 per cent. and 28 per cent., respectively. The largest producing countries after the United States are Belgium and Germany.

Properties.—Zinc has a bluish-white color, a peculiar taste, and a perceptible odor when rubbed. Its texture is laminated, and its fracture crystalline. Its malleability and ductility are not very great. When perfectly pure, it may be reduced to thin leaves at ordinary temperatures; but the zinc of commerce requires to be heated to a temperature between 100° C. and 148.8° C. (212° F. and 300° F.) to render it sufficiently malleable to be rolled into sheets. The softness of zinc is peculiar, as shown by the circumstance that it clogs the file when the attempt is made to reduce it to filings; and hence to have it in the divided form it is necessary to melt it, and triturate it at the

moment of solidification.¹ Subjected to heat it fuses at 398° C. (773° F.). According to A. von Riemsdyk, it volatilizes to some extent before fusion at a temperature of 268.3° C. (515° F.). (*A. J. P.*, 1869, p. 424.) At full redness it boils, and in close vessels may be distilled over; but in open vessels it takes fire, and burns with a dazzling white flame, giving off dense white fumes. It dissolves in most of the acids with disengagement of hydrogen, and precipitates all the metals either in the metallic state or in that of oxide. It forms but one oxide (a monoxide) and but one sulphide. The monoxide is official, and has been described under another head. (See *Zinci Oxidum*.) The official zinc is described as "a bluish-white metal, showing a crystalline fracture; in the form of thin sheets, or in irregular, granulated pieces, or moulded into thin pencils, or in fine powder, and having a specific gravity ranging from 6.9 when it is cast to 7.2 after it is rolled. Soluble in diluted sulphuric or hydrochloric acid with evolution of hydrogen. When heated above 100° C. (212° F.) and not above 150° C. (302° F.), the metal becomes malleable and ductile; above 200° C. (392° F.) it becomes sufficiently brittle to be powdered in an iron mortar; at 412° to 415° C. (773.6° to 779° F.) it melts, and at 940° C. (1724° F.) it boils and may be readily distilled. If 1 Gm. of Zinc be added to 20 Cc. of diluted hydrochloric acid, the liberated hydrogen should not have a disagreeable odor, nor should it color a strip of paper moistened with lead acetate T.S. (absence of *sulphur*), or with silver nitrate T.S. (absence of *arsenic*, *antimony*, and *phosphorus*). The resulting solution should be clear and colorless, and should yield a white gelatinous precipitate with potassium ferrocyanide T.S., and a white precipitate with ammonium sulphide T.S. If 1 Gm. of Zinc be dissolved in a mixture of 10 Cc. each of nitrohydrochloric acid and water, the solution evaporated to dryness, the residue moistened with 2 Cc. of hydrochloric acid and again evaporated, and the final residue dissolved in 10 Cc. of water, this solution should not respond to the Time-Limit Test for *arsenic*, *cadmium*, *lead*, and *copper* (see PART III, Test No. 121); in applying this test the addition of ammonia water should be omitted." *U. S.*

Zinc of good quality dissolves in diluted sulphuric acid, with the exception of a scanty grayish-black residue. If absolutely pure, it would be wholly dissolved. The solution is colorless, and yields white precipitates with potassium ferrocyanide and ammonium sulphhydrate. Ammonia throws down from this solution a white precipitate, which is wholly dissolved when the alkali is added in excess. Zinc is extensively employed in the arts. It is the best metal that can be used, in conjunction

with copper or carbon, for galvanic combinations. Its solution in diluted sulphuric acid furnishes the readiest method for obtaining hydrogen. With copper it forms *brass*, and, in the form of *sheet zinc*, it is employed to cover the roofs of houses, and for other purposes. It is also applied to the covering of iron, to protect it from oxidation, in the same manner as tin, forming what is commercially known as *galvanized iron*. A fine powder, known as *zinc dust*, obtained by the condensation of zinc vapor in the distillation of zinc from its ores, is much used in chemical laboratories as a convenient reducing agent in many reactions. Zinc should never be used for culinary vessels, as it is soluble in the weakest acids. Zinc and its oxide are dissolved to a certain extent by water containing common salt, a double zinc and sodium chloride being produced in solution. (*J. P. C.*, Nov. 1867, p. 397.)

The compounds of zinc are poisonous, but not to the same extent as those of lead. The zinc oxide, used in painting as a substitute for white lead, is said to be capable of producing a colic resembling that caused by lead, and called *zinc colic*. It attacks the workmen exposed to the dust of the oxide while engaged in packing it in barrels, and is said to yield to the remedies appropriate to the treatment of lead colic. This latter statement, however, is, to say the least, very questionable.

Uses.—Zinc is never used as a medicine in the metallic state, but is employed in this state to prepare zinc sulphate and zinc chloride, and the Reduced Iron of the Br. Pharmacopœia. In combination it forms a number of important preparations.²

² *Zinc Nitrate* is sometimes used as a caustic either in the form of *paste* or in *pencils*. Lefort prepares it by dissolving commercial zinc with heat in equal volumes of nitric acid and water, maintaining an excess of zinc, and concentrating until a slight basic precipitate is formed, which carries down any iron present. Boiling water is then added, and, when cool, the solution is filtered, and evaporated at a gentle heat until slight ebullition takes place; if then left to cool, it forms a cake, which should be broken up and drained in a glass funnel. Of the zinc nitrate so prepared, 100 grammes are dissolved in 50 grammes of water, and afterwards incorporated with 50 grammes of wheaten flour. This forms a homogeneous paste, which remains soft, spreads easily over surfaces without afterwards contracting, and does not spread at the edges through absorption of moisture. When made into cylinders, it should not be dried by heat, as it slightly decomposes and becomes yellow and friable. It may be kept dry by placing it in a tin box with some pieces of quicklime, but not in contact with them. (*L. M. R.*, June 18, 1873; *A. J. P.*, Dec. 1873.) Chas. Rice prepares pencils by pouring fused zinc nitrate into paper cylinders which are made by rolling paper around a lead-pencil and sealing with wax. (See *N. R.*, 1876, p. 44; also *Hydrargyri et Zinci Cyanidum*, PART II.) The mixed *mercury* and *zinc cyanide* was originally suggested as a practical antiseptic by Lister, who claimed for it the advantages of being non-volatile, unirritating, insoluble in water, and soluble only in three thousand parts of blood serum; so that it is not easily washed off the gauze by discharge from wounds. Its germicidal value is said to be very slight, but its inhibitory power to be such that a one-twelve-hundredth solution will permanently prevent putrefaction in animal fluids. *Cyanide gauze* may be made actively germicidal by impregnation with a solution of one to four thousand of corrosive sublimate. One great objection to the preparation is the difficulty of making gauze with it. The statements of Lister in regard to the best method of preparing the gauze are devoid

¹ *Zincum Granulatum*. Br. 1885. *Granulated Zinc*. "Take of Zinc of commerce *one pound*. Heat it in an earthen crucible, and immediately the metal is fused remove the crucible from the fire and pour the fluid in a thin stream into a vessel containing about two gallons of cold water. Drain off the water and dry the granulated zinc." Br. 1885.

Gingembre (grís et blanc), *Fr. Cod.*; Rhizoma Zingiberis, *P. G.*; Ingwer, *G.*; Zenzero, *It.*; Jengibre (Rhizoma de), *Sp.*

Zingiber officinale, Roscoe, *Trans. Lin. Soc.* (1807), viii. 348; Carson, *Illust. of Med. Bot.*, ii. 55, pl. 98.—*Amomum Zingiber*, L., *Sp. Plant.* 1753, 1; *B. & T.* 270.—The ginger plant has a biennial or perennial, creeping rhizome, and an annual stem, which rises two or three feet in height, is solid, round, erect, and enclosed in an imbricated membranous sheathing. The leaves are lanceolate, acute, smooth, five or six inches long by about an inch in breadth, and stand alternately on the sheaths of the stem. The flower-stalk rises by the side of the stem from six inches to a foot, and, like it, is clothed with oval acuminate sheaths; but it is without leaves, and terminates in an oval, obtuse, bracteal, imbricated spike. The flowers are of a dingy yellow color, and appear two or three at a time between the bracteal scales.

The plant is a native of Hindostan, and is cultivated in all parts of India. It is also cultivated in the West Indies, whither it was transplanted from the East, and at Sierra Leone in Africa. The flowers have an aromatic odor, and the stems when bruised are slightly fragrant; but it is in the rhizome that the virtues of the plant reside. This is fit to be dug up when a year old. The rhizome of the ginger is lifted from the soil by a single thrust of the fork at the time when the stems of the plant turn white, before the rhizome has begun to get tough and fibrous. The root is scalded in boiling water and rapidly dried, when it constitutes the *black* or ordinary ginger of commerce.

In Jamaica the so-called *white* or *Jamaica ginger* is produced by carefully peeling the fresh rhizomes so that only the epidermis is removed, the cells immediately beneath the epidermis being the richest in volatile oil and resin. The peeled pieces are macerated sometimes in water and sometimes in lime juice, and not rarely the color of the ginger is improved by finally coating it with chalk. An inferior white ginger is also produced in the

East Indies. The thoroughness of desiccation is a matter of commercial importance. The moisture in ginger should not exceed 10 per cent., but in the poorer specimens may constitute one-fourth of the whole weight. In China the fresh ginger is rasped into a powder and as such dried. Formerly *East Indian ginger* was imported into the United States from Calcutta, while the *Jamaica* or *West Indian ginger* came usually through London. At present the cultivation of ginger is spread almost over the whole sub-tropical world, and the drug is produced in St. Lucia, Dominica and Africa, Cochin-China, Japan, etc. In Martinique a ginger is said to be obtained by the cultivation of *Zingiber Zerumbet*, Rose.

The ginger of Siam is said to be produced by *Alpinia Galanga*, and is the same drug, therefore, as the *Grater* or *Java Galanga Root*. The large, ordinary, *preserved ginger* of China is, according to C. Ford (*Kew Bulletin*, 1891) also the product of *A. Galanga*. It is made by boiling young, tender, carefully selected and decorticated rhizomes in syrup. Preserved ginger from the West Indies is made from the official plant. According to Hartwich and Swanlund, the rhizome of the *Zingiber Mioga*, which is cultivated in China and Japan, has a taste less pungent than that of the official ginger, and distinctly recalling bergamot. In commerce the varieties of ginger are known by the place of their production. African and Cochin ginger on an average yield more resin and volatile oil than do the older varieties.¹

The recent root is from one to four inches long, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light ash color with circular rugæ, internally yellowish white and fleshy. It sometimes begins to grow when kept in a damp atmosphere. The *common* or *black ginger* is of the same general shape, but has a dark ash-colored wrinkled epidermis, which, being removed in some places, exhibits patches of an almost black color, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost horny cortical portion. The interior parenchyma is whitish and somewhat farinaceous. The powder is of a light yellowish-brown color. This variety is most extensively used. The *Jamaica* or *white ginger* is white or yellowish white on the outside. The pieces are rounder and thinner, and afford when pulverized a beautiful yellowish-white powder.

The uncoated ginger of the East Indies resembles the Jamaica, but is darker, being gray rather than white. As the Jamaica commands a much higher price than even the uncoated East India production, the latter is occasionally altered to simulate the former. This is some-

of the accuracy essential to pharmaceutical success. His method is by "mixing a pretty strong solution of starch with the double cyanide powder, and adding to this a quantity of ground potassium sulphate. The resultant precipitate is dried, and when used is diffused in water in a trough, at the bottom of which the absorbed gauze is placed in layers; when soaked the gauze is drawn out and dried, or if to be used immediately is folded for a moment or two in a towel. When used the gauze may be wet with the corrosive sublimate solution, one to four thousand." (See *B. M. J.*, ii. 1889; also *Annals of Surgery*, Jan. 1891.)

¹ For tables giving analyses of varieties of ginger and for discussion of the methods of discovering the presence of *spent ginger* see *The Analyst*, vol. xviii. and xix.: *A. J. P.*, 1881, 894; *Bulletin No. 13*, Part II, U. S. Dept. of Agriculture, 1887; *P. J.*, vol. lxxi.

times done by coating the exterior with calcium sulphate or carbonate, sometimes by bleaching with the fumes of burning sulphur or in other ways, by which not only the exterior but also the internal parts are rendered whiter than in the unprepared root. Powdered ginger which has been exhausted in the preparation of essence, technically known as "*spent ginger*," is used to a large extent in the adulteration of powdered ginger. Its detection without assay of some sort is almost impossible, unless so much is present as to sensibly alter the taste of the powder. Allen and Moor rely upon the proportion of cold water extract yielded and the soluble ash. Dyer and Gilbard state that the fixed ethereal extract is of little value, on account of its variability in genuine ginger, but that the extract obtained by alcohol after ether affords a valuable criterion. In genuine ginger the average yield is 2.9 per cent. while in spent ginger it is 1.2 per cent. They also affirm that in genuine ginger the ash produced is 2.7 per cent., in the exhausted ginger it is 0.3 per cent. A. Russell Bennett concludes that spent ginger can be detected by noting the alcoholic and cold water extracts and the soluble ash, affirming that ginger should yield not less than 5 per cent. of extract with 90 per cent. alcohol, 8.5 per cent. of cold water extract and 1.5 per cent. of soluble ash.

Properties.—The U. S. Pharmacopœia describes this rhizome as in "laterally compressed, irregularly branched pieces; externally whitish or pale buff, longitudinally striate; fracture short-fibrous, mealy, showing numerous small oil and resin cells and circular groups of fibro-vascular bundles; odor agreeably aromatic; taste aromatic and pungent." *U. S.* The odor of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and are ultimately lost, by exposure. The virtues of ginger are extracted by water and alcohol.

The peculiar flavor of the root appears to depend on the volatile oil, its pungency partly on the resinous or resino-extractive principle. A considerable quantity of pure white starch may be obtained from it. The volatile oil, examined by A. Papousek, was yellow, of the odor of ginger, and of a hot aromatic taste. Its sp. gr. was 0.893, and its boiling point 246.1° C. (475° F.). Deprived of water by distillation over phosphoric oxide, it consisted of carbon and hydrogen, with the formula $C_{10}H_{16}$, and therefore belongs to the terpenes.

Thresh considers that the essential oil is mainly made up of a hydrocarbon, $C_{15}H_{24}$, or isomers of it, which boil at from 245° to 270° C. (*P. J.*, No. 586, 1881.) Schimmel & Co. (April, 1897) state that the essential oil contains *camphene* and *phellandrene*, and hence the terpenes have the formula $C_{10}H_{16}$, as first stated. Flückiger obtained from one hundred and twelve pounds of Jamaica ginger four and a half ounces of the oil, or about one-fourth of one per cent. He states, however, that Schimmel & Co. of Leipsic, informed him that they obtained as much as 2.2 per cent. from good ginger. (*Pharmacographia*, 2d ed., p. 637.) H. von Soden and W. Rojahn (*Ph. Ztg.*, 1900, 414) obtained a new sesquiterpene from oil of ginger by fractioning the saponified oil. They have named it *zingiberene*. It has the sp. gr. 0.872 at 15° C. Those pieces of ginger which are very fibrous, light and friable, or worm eaten, should be rejected. The commercial powder of ginger is very frequently adulterated, rice starch, powdered ginger which has been exhausted in making preparations, and even brick dust and chalk, being used, and the loss of pungency made good by the addition of capsicum or mustard.

Uses.—Ginger is a grateful stimulant and carminative, and is often given in *dyspepsia*, *flatulent colic*, and the feeble state of the alimentary canal attendant upon *atonic gout*. It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. Externally it is rubefacient. Under the name of "*Essence of Ginger*" cheap alcoholic preparations of ginger have been much sold and used as an intoxicant. A number of cases of blindness produced by such use have been recorded, the amblyopia having been due to the large use of methyl alcohol in the making of these "essences." The infusion may be prepared by adding half an ounce of the powdered or bruised root to a pint of boiling water, and may be given in the dose of one or two fluid-ounces (30 to 60 Cc.).

Dose, ten to twenty grains (0.65 to 1.3 Gm.).

PART II

DRUGS AND MEDICINES NOT OFFICIAL

IN the present section it is proposed to consider remedies which are not recognized in the United States or British Pharmacopœias, but which on account of their use in domestic or professional medicine, their toxic properties, their history, or the probability that they may prove in the future remedies of power, or valuable products, require notice in an encyclopedic work like the United States Dispensatory. The limit of the present volume forbids a complete description of all these substances, but the attempt is made to give at least the information where to look for an account of almost everything used in medicine. As the substances treated of in this part are not official, they are not considered to be of as great importance as those found in Part I. and hence the type and arrangement of titles are different; experience has shown that this method educates the reader to distinguish between official and unofficial substances.

Abrastol. *Asaprol*.—Calcium *a*-monosulphonate

$$\begin{array}{c} \text{C}_{10}\text{H}_7 \left\{ \begin{array}{l} \text{OH} \\ \text{SO}_3 \end{array} \right. \\ \text{of } \beta\text{-naphthol,} \\ \text{C}_{10}\text{H}_7 \left\{ \begin{array}{l} \text{SO}_3 \\ \text{OH} \end{array} \right. \end{array} \text{Ca. This is a white}$$

powder, soluble in water and alcohol, and resembling the salicylates in its taste. It is said to be neutral in reaction, readily soluble in alcohol and water, and not altered by heat, non-irritant, slightly toxic, well borne by the digestive tract, and rapidly eliminated by the kidneys. *Asaprol* was originally brought forward by A. Stackler as a germicide, antipyretic, and antirheumatic, to be used in doses of from fifteen to sixty grains (1-3.9 Gm.) in *rheumatism*, *typhoid fever*, etc. (B. G. T., 1892.) Dujardin-Beaumez (*Ibid.*, Jan. 1894) finds that when given by the mouth to rabbits in the dose of 0.25 gramme per kilo it has no deleterious effect, although less than one gramme per kilo proves fatal. It escapes from the kidneys in the form of *sulphuric ether-naphthol*, which is to be recognized by the dark blue coloration of the urine on the addition of ferric chloride. In acute *rheumatism*, Dujardin-Beaumez believes that the remedy is equal to salicylates, and that it has the advantage of not producing *tinnitus aurium* or eruptions upon the skin. From sixty to ninety grains (3.9-5.8 Gm.) may be given daily in capsules or aqueous solution. Buck (*Ther. Woch.*, 1897) confirms the value of *asaprol* in *rheumatism*. Moncorvo (B. G. T., March and April, 1895) recommends it in *chorea* and in *malarial diseases*. He also affirms that, used locally, it is an excellent antiseptic, hæmostatic, and cicatrizing. He uses it in aqueous solution, 1 to 4 per cent., or as an ointment with vaseline. He even asserts that a 1 per cent. solution applied to the periglottal region will rapidly cure *whooping cough*.

Abroma. *Abroma angusta*, L. f. (Fam. Sterculiaceæ.)—Under the name of *Olutkombul*, the glutinous sap of this plant has long been used in India in *dysmenorrhœa*. According to Sircar (*Indian Medical Gazette*, 1900) and other English practitioners, it is a very efficient remedy in congestive and neuralgic *dysmenorrhœa* when given in doses of two drachms (7.7 Gm.) at the time of the first premonitory pains and continuing to the end. The fresh root is sometimes used. Dose, half a drachm (2 Gm.).

Abrus. *Abrus precatorius*, L. *Jequirity*. *Kunch. Ratti*. (Fam. Leguminosæ.)—The seeds of this plant, which grows in India and also in Brazil, are employed in India as a standard weight, and also for criminal poisoning. They are said to be inert when taken whole into the stomach. They contain *abroic acid*, $\text{C}_{12}\text{H}_{24}\text{N}_3\text{O}$, and, according to the researches of Sidney Martin (P. J., Sept. 1887; *Proc. Roy. Soc.*, vol. xlv., 1889), two proteid poisons, a paraglobulin and an albumose (together called *abrin*), which are almost identical in their physiological properties with principles found in snake venom, although less powerful. According to Flexner, the toxic action of these substances also closely resembles that of true toxins, the most characteristic result being focal necroses in various organs. Flexner suggests that these in turn are due to a lesion in the blood vessel walls caused by the *abrin*. (J. Ex. M., 1897, vol. ii.) The ordinary lethal dose of *abrin* for animals is said to be 0.00001 Gm. per kilo of weight. (Consult *The Non-Bacillous Nature of Abrus Poisoning*, J. H. Warden and L. A. Waddell, Calcutta, 1884; Bufalini, *Ann. di Chim. e di Farm.*, No. 2, 1886; Kobert, W. M. B., Nov. 1889.) The root is used as a substitute for licorice, and, according to David Hooper, contains *glycyrrhizin*. (P. J., 1894.) The

infusion of jequirity was formerly used as a local remedy in *granular conjunctivitis*, *pannus*, *trachoma*, and other diseases of the eye; but the preparation has been supplanted by a definite solution of abrin. According to Ehrlich, the solution of abrin should not be stronger than one part in 500,000; any increase of strength must be made with great care. Both Ehrlich and Calmette succeeded in immunizing rabbits against abrin, and obtained an antitoxin serum. P. Römer (Graefe's *Archiv f. Ophthalm.*, vol. lii., 1901) has introduced two preparations: *jequiritol*, an abrin solution, sterilized, of four different strengths; *jequiritol serum*, which, as commercially supplied, has such immunizing power that 0.1 Cc. suffices to protect a white mouse from the effects of a hundredfold lethal dose of jequiritol when the latter and jequiritol serum are injected conjointly. (For details and methods of use, see *Th. M.*, May, 1902; *M. R.*, 1902; also Kattwinkel, *Jequiritol*, Bonn, 1902.)

Absinthium. U. S. 1890. Wormwood.—“The leaves and tops of *Artemisia Absinthium*, L. (nat. ord. Compositæ).” U. S. 1890. Several species of *Artemisia* have enjoyed some reputation as medicines. The leaves of *A. Abrotanum*, L., or *southernwood*, are reported by Craveri to contain a crystallizable alkaloid, *abrotine*; they were formerly employed as a tonic and anthelmintic. *A. pontica*, L., has been substituted for common wormwood, but is weaker. *A. vulgaris*, L., or *mugwort*, has been used in Germany in *epilepsy*, *chorea*, and *amenorrhœa*. *A. ludoviciana*, Nutt., a native of the southwestern regions of the United States, has been commended as a stimulant to the hair. (*A. J. P.*, 1872, p. 106.) In China, *mosa* is prepared from *A. chinensis*, L., and *A. indica*. Wormwood is a perennial plant, with branching, round, and striated or furrowed stems, which rise two or three feet in height, and are panicked at their summit. The radical leaves are triply, those of the stem, doubly or simply pinnatifid. The floral leaves are lanceolate. The flowers are of a brownish-yellow color, hemispherical, pedicelled, nodding, and in erect racemes. The plant is a native of Europe, where it is also cultivated. It is among our garden herbs, and has been naturalized in the mountainous districts of New England. It should be gathered in July or August, during flowering. “Leaves about 5 Cm. long, hoary, silky-pubescent, petiolate, roundish-triangular in outline; pinnately two- or three-cleft, with the segments lanceolate, the terminal one spatulate; bracts three-cleft or entire; heads numerous, about 3 Mm. long, subglobose, with numerous small, pale-yellow florets, all tubular and without pappus; odor aromatic; taste persistently bitter.” U. S. 1890. The volatile oil (*oleum absinthii*) is usually dark green, sometimes yellow or brownish, having a strong odor of the plant, an acrid peculiar taste, and the sp. gr. 0.925 to 0.950. It is sometimes adulterated with alcohol, oil of turpentine, etc., which lessen its specific gravity. It is composed of *thujone* (*absinthol*), which has the specific gravity 0.926, composition $C_{10}H_{16}O$, boiling point $200^{\circ} C.$ ($392^{\circ} F.$) to $205^{\circ} C.$, and when heated with phosphorus pentasulphide or zinc chloride yields *cymene* ($C_{10}H_{14}$); *thujyl alcohol* ($C_{10}H_{18}O$), both free and as the esters of *acetic*, *isovaleric*, and *palmitic acids*; *phellandrene* and possibly *pinene*; *cadinene*; and a *blue oil* of as yet undetermined composition. (Gildemeister and Hoffmann, *Aetherische Oele*, 1899.) Accord-

ing to Braconnot, wormwood also contains chlorophyll, albumen, starch, saline matters, and lignin, malic and acetic acids. The cold infusion becomes olive-green and turbid on the addition of ferric chloride, indicating the probable existence of a little tannic acid. (Pereira.) The *absinthic acid* found by Braconnot is said to be succinic acid. Caventou first obtained *absinthin* in an impure condition. (See U. S. D., 14th ed., p. 5.) E. Luck prepared pure *absinthin* in 1851. (*A. J. P.*, xxiii. 358.) A. Kromayer (*A. Pharm.* (2), cviii. 129) gave to *absinthin* the formula $C_{20}H_{28}O_4 + \frac{1}{2}H_2O$. P. Senger (*A. Pharm.*, 230, p. 94) has obtained *absinthin* as a yellow substance of an intensely bitter taste melting at $55^{\circ} C.$ He gives it the formula $C_{15}H_{20}O_4$ and considers it to be a glucoside, as on boiling with diluted sulphuric acid it yields dextrose and *absinthic acid*. *Absinthin* is soluble in water, alcohol, and ether. Adrian and Trillat isolated a new crystalline body ($C_{83}H_{51}O_{20}$) from wormwood by treating an alcoholic extract with amyl alcohol, the *absinthin* having been previously removed. They also isolated another crystalline principle, *anabsinthin*, $C_{15}H_{24}O_4$ (*P. J.*, 1899, 1, 75). The old salt of wormwood (*sal absinthii*) was impure potassium carbonate, made from the ashes of the plant.

Wormwood, which was formerly in vogue as a stomachic tonic, antiperiodic, and anthelmintic, is at present very seldom used by regular practitioners. The volatile oil is an active narcotic poison. In dogs and rabbits from thirty to fifty drops (1.5–2.5 Cc.) of it will cause trembling, stupor, hebetude, and it may be insensibility; one to two fluidrachms (3.75–7.5 Cc.) of it, violent epileptiform convulsions, with involuntary evacuations, unconsciousness, and stertorous breathing, which may or may not end in death. (Marcé, *B. G. T.*, Mai, 1864; Magnan, *L'Union Méd.*, Août, 1864; Amory, *B. M. S. J.*, March, 1868, p. 83.) In man the oil acts similarly; a half-ounce (15 Cc.) of it caused, in a male adult, insensibility, convulsions, foaming at the mouth, and a tendency to vomit; though the patient recovered under the use of emetics, with stimulants and demulcents. (*L. L.*, Dec. 6, 1862.) According to J. L. Corning, the volatile oil is a powerful local anæsthetic, locally useful in *rheumatic pains*. Böhm and Kobert affirm that the oil escapes through the kidneys unchanged. *Dose*, of wormwood in substance, from twenty to forty grains (1.3–2.6 Gm.); of the infusion (one ounce in a pint of boiling water), from one to two fluidounces (30–60 Cc.); of the oil, one to two minims (0.06–0.12 Cc.).

Absinthe is a liqueur containing oils of wormwood, angelica, anise, and marjoram. According to Baudrimont the *absinthe ordinaire* contains 47.66 per cent. of alcohol, the *demi-fine* 50 per cent., the *fine* 68 per cent., and the *absinthe Suisse* 80.66 per cent. The preparation, if manipulated properly, possesses naturally a bright green color, brought to an olive-green by slight addition of caramel coloring; but artificial coloring is often resorted to, and indigo, turmeric, cupric acetate, and aniline green have been used to produce the proper shade. *Absinthism* differs from ordinary alcoholism in its manifestations; its characteristic symptoms are restlessness at night, with disturbing dreams, nausea and vomiting in the morning, with great trembling of the hands and tongue, vertigo, and a tendency to epileptiform convulsions.

Acacia Bark. *Acacia Cortex. Br. Add.* Under the name of *Acacia Bark* the British Addendum recognizes under one name the dried barks of the *Acacia arabica* (Lam.), Willd., and of the *Acacia decurrens*, Willd., or *Black Wattle* of Australia.

Acalypha. *Br. Add.*—The fresh and the dried herb, *Acalypha indica*, L. This euphorbiaceous plant is said to have expectorant and emetic properties similar to those of ipecac, and also to be employed by the native Indian practitioners in the form of the fresh leaves as a poultice for ulcers, and as a suppository for constipation in children. The *Succus Acalyphæ*, *Br. Add.*, is prepared by adding one volume of 90 per cent. alcohol to three volumes of the juice expressed from fresh leaves, with subsequent filtration. It is given in doses of from one to four fluidrachms (3.75–15 Cc.). The *liquid extract* (*Extractum Acalyphæ Liquidum*, *Br. Add.*), made with a menstruum of 90 per cent. alcohol, is given in doses of from five to thirty minims (0.3–1.8 Cc.).

Acetal. $C_6H_{14}O_2$ or $CH_3CH(OC_2H_5)_2$.—*Ethylidene diethyl ether*, a limpid liquid boiling at 104° to 106° C. (219° – 223° F.), sparingly soluble in water, readily soluble in alcohol, is stated to be narcotic in the dose of thirty minims (1.8 Cc.).

Aceto-Ortho-Toluid. $C_7H_7.NH.C_2H_5O$.—Colorless needles, easily soluble in hot water, alcohol, and ether; powerfully depressant to animal temperature, although feebly poisonous. (E. Barbarini, *T. Mod.*, 1892, 532.)

Acetophenone. *Hypnone.* *Phenyl-methylketone*, C_8H_8O or $C_6H_5CO.CH_3$.—A colorless liquid, boiling at 200° C. (392° F.), having a very tenacious, persistent odor, recalling that of bitter almonds, not inflammable, not soluble in water or in glycerin, but very soluble in alcohol, ether, chloroform, petroleum benzin, and also certain oils, especially that of sweet almonds. It is made by distilling a mixture of calcium acetate and benzoate. Originally proposed as a hypnotic by Dujardin-Beaumetz, it has been shown by the concordant researches of Laborde, Grasset, Mairet, and Combemale to be very uncertain as a hypnotic and very toxic in its action on the lower animals. The researches of Regnier, confirmed by Kamensky, have demonstrated that it acts powerfully on nutrition, rapidly lessening the hæmoglobin in the blood and causing loss of weight. In agreement with this, it has been found to be in man an uncertain hypnotic. Norman, however, claims excellent results from hypodermic injections of from five to twelve minims (0.3–0.7 Cc.) in *insanity* (*J. M. S.*, xxxiii.). *Dose*, from three to ten minims (0.2–0.6 Cc.), although Rey has given as much as twenty-three grains (1.5 Gm.) without producing sleep.

Acetophenone-Paramidophenol Ether.—This substance, prepared by G. Vignolo, has been studied physiologically by F. Badano (*Arch. I. C. M.*, xxxvi. 1897), who finds that it powerfully reduces bodily temperature by lessening the heat production; that in poisonous doses it causes the formation in the blood of methæmoglobin, and kills by respiratory paralysis.

Acetopyrine. *Antipyrine* *Acetyl-salicylas*. This occurs as a white crystalline powder, having an odor resembling acetic acid; sparingly soluble in cold but freely in warm water; freely soluble in alcohol, chloroform, and in warm toluol; less so in ether and in petroleum benzin. It was originally introduced into medicine by Winterberg and

Braun (W. K. W., 1900, No. 39) as combining the activities of antipyrine and salicylic acid, into which substances, according to W. Meitner (*St. P. M. W.*, xx. 1900), it is broken up in the stomach; the acetyl-salicylic acid undergoing further decomposition in the intestines. Acetopyrine has been much used as an analgesic in *migraine*, *sciatica*, *neuritis*, and also as an antipyretic in *typhoid* and other low fevers. It has also been employed as an antirheumatic, especially in subacute and chronic cases. Goldmann (*All. W. M. Z.*, April, 1901) claims that it is valuable in *bronchitis*; and Bolognesi (*B. G. T.*, March, 1901) recommends it in *gonorrhœa*. Its physiological and therapeutic activities are probably those of its constituents. It may be given in doses of five to ten grains (0.32–0.65 Gm.), in capsules or suspended in water, and repeated up to thirty grains (2 Gm.) in the twenty-four hours when necessary. In fevers two doses may be given two hours apart about the time of the exacerbation.

Acetylene. C_2H_2 .—Acetylene was first prepared by Berthelot, who obtained it by passing the electric spark between carbon points in an atmosphere of hydrogen. It is now prepared on a large scale by the decomposition of carbides like calcium carbide with water according to the reaction:

The product so obtained is almost always contaminated with phosphine, and this should always be removed by washing the acetylene with bromine water.

Calcium carbide, CaC_2 , is prepared by melting a mixture of powdered lime and coke dust in an electrical furnace. It is a grayish-brown, dense substance having a crystalline metallic fracture and the specific gravity of 2.26. It evolves a peculiar odor when exposed to the atmosphere, due to the action of moisture which causes partial decomposition with the production of acetylene. When exposed to the air, in lumps, it becomes coated with a layer of calcium hydroxide, which to a great extent protects the interior of the lumps from further deterioration. Calcium carbide is not inflammable and one pound if pure yields 5.9 cubic feet of acetylene gas at 18° C. The production of calcium carbide in the United States in 1904 was 31,642,000 pounds, valued at \$1,088,420.

Acetylene is a colorless gas of ethereal odor, slightly soluble in water, more readily in alcohol and ether, and most abundantly in acetone. It burns ordinarily with a very smoky flame, but from a burner with a fine slit gives a clear white flame. It forms an explosive mixture with air, also a series of explosive acetylides with copper, silver, and other metals.

According to Mosso and Ottolengui (*Rendiconti Della R. Accademia dei Lincei*, 1896) acetylene gas is an active poison, causing death in the dog in about one minute through respiratory failure, and always producing a fatal result when present in the air in more than twenty per cent. Rosemann (*A. E. P. P.*, xxxvi. 1895) asserts that its toxic properties are very feeble, and that it has no action upon hæmoglobin.

In Moissan's experiments from 40 to 79 per cent. of the vapor was necessary in the air breathed before toxic manifestations were produced (*C. R. A. S.*, cxxi), while Oliver found that no symptoms were caused so long as even a moderate amount of atmospheric air was main-

tained with the vapor, and when the animal was made to breathe pure acetylene gas the symptoms were very similar to, if not identical with, those of asphyxiation. (*B. M. J.*, i. 1898.)

Acetylphenylhydrazin. $C_6H_5NH.NH.CH_3CO$. This substance, first introduced into medicine in an impure form, under the name of *pyrodin*, has since been used in an alleged pure condition under the name of *hydracetin*. It is chemically closely allied to acetanilide, differing solely in the possession of one imido-group (NH); it is, as indicated by its name, hydrazin in which hydrogen atoms are replaced by phenyl and acetyl. It is made by heating together phenylhydrazin and glacial acetic acid, and purifying the product by recrystallization. It forms colorless, inodorous crystals, melting at $128.5^\circ C$. ($263^\circ F.$), soluble in fifty parts of water and readily soluble in alcohol. Guttman (*Pr. M. W.*, 1889) demonstrated that this substance is a powerful poison, seven and a half grains (0.5 Gm.) being sufficient to kill a rabbit, with a remarkable destruction of the red blood cells. He found it a powerful antipyretic, in doses of from one and a half to two and a half grains (0.096–0.16 Gm.), but believes it to be a very dangerous remedy on account of its action on the blood. Externally he considered it to be safe, and allied to pyrogallie acid in its influence upon skin diseases; but Basch (*L. L.*, 1890) has seen very violent poisoning from the use of a 10 per cent. ointment, without benefit to the *psoriasis*. On the other hand, Lemoine (*B. M.*, 1889) finds it, in doses of three-fourths of a grain (0.048 Gm.), a valuable remedy in the treatment of *hectic fever* of *phthisis*, reducing the temperature and checking night-sweats. When the dose of two and a half grains (0.16 Gm.) per day is exceeded, violent symptoms are apt to be produced.

Achillea. *U. S.* 1870.—The flowering tops of *Achillea Millefolium*, *L. Milfoil*, or *yarrow*, is a perennial herb, very common both in Europe and America. It is from a foot to eighteen inches high, and is specifically distinguished by its doubly pinnate, downy, minutely divided leaves, with linear, dentate, mucronate divisions, from which it derived the name of milfoil, by its furrowed stem and involucre, and by its dense corymbs of whitish flowers, which appear throughout the summer, from June to September. The whole herb is medicinal. *Achillea nobilis*, *L.*, and *A. moschata*, *Jacq.*, or *Iva* of Europe, are sometimes used as substitutes for *A. Millefolium*.

Both the flowers and leaves of *A. Millefolium* have an agreeable, though feeble aromatic odor, which continues after drying, and a bitterish, astringent, pungent taste. The aromatic properties are strongest in the flowers, the astringency in the leaves. The plant contains, besides, a blue volatile oil, tannin, and a peculiar principle, *achillein*, which was discovered by Zanon. (*Ann. Ch. Ph.*, lviii. 21.) As analyzed by von Planta (*Ann. Ch. Ph.*, clv. 1870) its formula is $C_{20}H_{38}N_2O_{15}$. It occurs in a brownish-red mass of a strongly bitter taste, soluble in water, more feebly in alcohol, and not at all in ether. *Achilleic acid*, also discovered by Zanon, is affirmed by Hlasiwetz to be identical with aconitic acid. The oil, which may be obtained separately by distillation with water, has a beautiful azure-blue color, and the peculiar flavor of milfoil. Schimmel & Co. (*Ber. d. Chem. Ges.*, 1894, p. 50) found its most important constituent to be *cineol*, $C_{10}H_{18}O$. The high boiling blue portion is probably identi-

cal with the azulene of chamomile oil. *Ivain*, $C_{24}H_{42}O_6$, has also been isolated; it occurs as a dark yellow resinous mass, insoluble in water, readily soluble in alcohol, and producing an intensely bitter solution.

The active principles of the drug are extracted both by water and alcohol. *A. Millefolium* is a mild aromatic sudorific tonic and astringent, and is sometimes used in acute suppression of the menses, in the form of a hot infusion. Dose, from four to six fluidounces (120–180 Cc.); the volatile oil has been used in doses of twenty or thirty drops (1.0–1.5 Cc.). Pappi states that *achillein* given in divided doses up to from thirty to seventy-five grains (2–5 Gm.) causes marked irregularity of the pulse.

Di-para-anisyl-mono-para-phenetyl-guanidine Hydrochloride.—A white crystalline powder, soluble in water (six parts to one hundred). It is incompatible with iodine or alkaline iodides. Acocine was introduced as a local anæsthetic by Trollenier (*Th. M.*, xiii.; also *Zeit. T. M.*, 1901). It has been specially used by the ophthalmologists in a 1 per cent. aqueous solution, stronger solutions being very irritant or even corrosive. It is not absorbed through a normal conjunctiva, but when the epithelial covering is destroyed, or when the drug is injected into the sub-conjunctival tissues, it is said to act more powerfully than cocaine, and to be specially efficacious in the relief of deep seated ocular pains. It is also actively germicidal, the 1 per cent. solution remaining free from bacteria. Acocine has also been used with asserted excellent results in dentistry and in operations upon the nose. For dental purposes a 2 per cent. solution is preferred. One per cent. of common salt should be added to hypodermic solutions, which are preferably made with distilled water.

Acrolein. *Acrylic Aldehyde*. $CH_2 = CH.CHO$. Acrolein is a fluid which emits an intensely pungent odor, is soluble in two or three parts of water, and boils at $52.5^\circ C$. ($126.5^\circ F.$). It is asserted by E. Koch and G. Fuchs (*Ch. B.*, 1899, xxvi.) to be a valuable bactericide, but its exceedingly disagreeable odor and tendency to undergo decomposition will probably prevent its coming into use.

Actæa. *Actæa spicata*, *L.* Baneberry. *Herb Christopher. Radix Christophoriana. Racine de Saint Christophe*, *Fr. Christophswurz, Wolfs-wurz, G.*—This is a perennial, herbaceous plant (*Fam. Ranunculaceæ*) growing in the woods of mountainous regions from Japan to Central Europe as well as in Siberia. Its dark-brown, bitterish, somewhat acrid root resembles that of *Helleborus niger*, for which it is said to be occasionally substituted. It is an active emeto-purgative, capable of producing when in overdose dangerous effects. There are two American species which probably have medicinal properties similar to those of *A. spicata*,—namely, *A. alba* (*L.*), *Mill.*, or *white cohosh*, and *A. rubra* (*Ait.*), *Willd.*, or *red cohosh*, distinguished by the color of their berries. (*Proc. A. Ph. A.*, 1858.)

Actinomeris. *Actinomeris helianthoides*, *Nutt. Gravel Weed. Diabetes Weed.* (*Syn. Verbesina helianthoides.*) (*Fam. Compositæ*).—The root is said to be largely used in Upper Georgia in *dropsy* and *chronic cystitis*. Dose of infusion (ounce to a pint), one fluidounce (30 Cc.).

Adansonia. *Adansonia digitata*, L. *Baobab*. A tree of enormous magnitude, belonging to *Bombacaceæ*. It is a native of Africa, extending quite through that continent from Senegal to Abyssinia, and has been introduced into the West Indies. The leaves and bark of this tree abound in mucilage, and have little odor or taste. By the Africans the leaves are used as a diaphoretic, and the subacid pulp of the fruit in *dysentery*. Under the name of *cream-of-tartar tree* various trees whose fruit contains or has been supposed to contain potassium bitartrate are spoken of in books. The most important of these is the *Adansonia Gregorii*, F. Muell., of North Australia. Another cream-of-tartar fruit is yielded by a tree of South Africa, which, according to E. M. Holmes, is probably the *Adansonia madagascariensis*, Baillon. This fruit has been examined by E. J. Millard (*P. J.*, April, 1890), who found that it contains no cream of tartar at all. It is probably identical with a cream-of-tartar fruit examined by F. L. Slocum. (*A. J. P.*, 1880.) It is worthy of remark that Heckel and Schlagdenhauffen (*Nouv. Rem.*, xxi. 487) have found in the fruit of the *Adansonia digitata*, or the baobab tree, as much as 2 per cent. of free tartaric acid and 12 per cent. of potassium bitartrate. Duchassaing of Guadeloupe, West Indies, and Pierre of France, commend the bark of *A. digitata* highly as an antiperiodic. (*A. G. M.*, 3e sér., xxiii. 535.) It is said to be acceptable to the stomach, and to produce no other observable physiological effect than increase of appetite, increased perspiration, and perhaps diminished frequency of pulse. An ounce may be boiled in a pint and a half of water to a pint, and the whole taken in a day. (*J. P. C.*, 3e sér., xiii. 412 and 421.)

Adenanthera. *Adenanthera pavonina*, L. *Zangavara*.—Rochebrune (*Toxicologie Africaine*) states that he has obtained from this plant a crystalline principle which resembles in its activity physostigmine, but does not affect the muscles.

Adenia. *Adenia venenata*.—A climbing passion-flower of Africa, said by Schweinfurth to be used as a vesicant. (*P. J.*, March, 1874.)

Adhatoda. *Br. Add.* (Nat. Ord. *Acanthaceæ*.) The fresh and the dried leaves of *Adhatoda vasica*, Nees. (*Justicia Adhatoda*, L.) "The fresh leaves are five or six inches (about twelve and a half to fifteen centimetres) long and an inch and a half (nearly four centimetres) broad, lanceolate, entire, taper-pointed, smooth on both sides. The dried leaves are of a somewhat dark green color which becomes much lighter when the leaves are powdered. They have a strong characteristic tea-like odor and a bitter taste." The leaves are stated to contain an alkaloid, *vasicine*, and an organic acid, *adhatodic acid* (see *Pharmacog. Indica*, vol. iii.). *Vasicine*, isolated by Hooper, is soluble in water, sparingly in benzoin and carbon disulphide, readily soluble in ether and chloroform. The claim is made for it that it exerts a powerful toxic influence upon lower forms of vegetable and animal life, and is not poisonous to the higher animals. The leaves are stated to be actively poisonous to frogs and are considerably used in India as an expectorant and antispasmodic, especially in the treatment of *asthma*. The *Br. Add.* recognizes the *liquid extract* (*Extractum Adhatodæ Liquidum*, *Br. Add.*), made with alcohol and given in doses of from twenty to sixty minims (1.3–3.75 Cc.); the freshly expressed juice (*Succus Adhatodæ*, *Br. Add.*), dose, from one to four fluidrachms (3.75–15 Cc.);

the *tincture* (*Tinctura Adhatodæ*, *Br. Add.*), dose, from one-half to one fluidrachm (1.8–3.75 Cc.).

Adiantum. *Maidenhair*.—Tradition has attached to various species of this genus of ferns properties according to which it is valuable in chronic pulmonic *catarrhs*, as well as in other conditions. *A. pedatum*, L., of America; *A. Capillus-Veneris*, L., of Europe; *A. lunulatum*, Burm., of India, are the most important of these alleged medicinal species. The European species is sometimes employed on the Continent as an emmenagogue under the name of *polytrichi*, *polytrichon*, or *kalliphyllon*, and is given in the form of infusion, sweetened with sugar or honey, and a syrup prepared from it is said to be popular in France under the name of *sirop de capillaire*, official in the *Codeex*.

Adonis. *Adonis vernalis*, L.—This ranunculaceous plant of Northern Europe and Asia has long been used as an abortifacient, while its rhizome sometimes occurs in commercial black hellebore as an adulteration. Linderos examined the leaves and found in them 10 per cent. of *aconitic acid*. (*Ann. Ch. Ph.*, 1876, 340.) Cervoello, in 1882, obtained from the plant a glucoside, to which he gave the name of *adonidin*. For improved method of preparation, see *P. J.*, vol. xvi. 145, and *A. J. P.*, 1887, 609. This glucoside occurs in the form of a somewhat hygroscopic, canary-yellow powder of an intensely-bitter taste; soluble in water, alcohol, and in amyl alcohol; insoluble in anhydrous ether, chloroform, oil of turpentine, and petroleum benzin. Its reaction is neutral. It reduces Fehling's solution, if previously heated with a few drops of hydrochloric acid. It exists in small quantities in all portions of the plant. For further details as to reactions, see *P. J.*, xv. 145. Podwysotszki found commercial samples of *adonidin* to be mixtures of the active principle with other constituents of the plant. He gives the name of *piroadonidin* to the active principle, which he describes as an amorphous glucoside having an excessively bitter taste, possessing the properties of a cardiac poison in the highest degree, and being easily soluble in water and alcohol and entirely soluble in ether. (*P. J.*, xix. 1888, 346.) According to Cervoello (*A. E. P. P.*, xv.), *adonidin* exists also in the *Adonis cupaniana* of Southern Europe, and F. Borgiotti affirms the value of *A. æstivalis*, L., in heart affections. (*D. M. Ztg.*, Aug. 1888.) Tahara asserts that the glucoside of *Adonis autumnalis*, L., is distinct, and calls it *adonin* ($C_{24}H_{40}O_9$) (*Ber. d. Chem. Ges.*, xxiv.), while Y. Inoko (*A. E. P. P.*, xxviii.) affirms that the glucoside of *A. amurensis* of Japan is also peculiar, and assigns to it the formula $C_{20}H_{40}O_9$, allied to *adonidin*, but much less powerful.

Merck has described an additional crystalline principle, which fuses at 102° C. (216° F.), is very soluble in water and warm alcohol, and crystallizes in clear needle-like prisms. It has a neutral reaction, does not reduce Fehling's solution, and is not colored brown by alkalis. Its analysis seems to indicate a formula $C_8H_{12}O_5$, and Merck considers that it is a hitherto undescribed pentatomic alcohol, and calls it *adonite*. Whether it be identical with the *adonidulcite* announced in a preliminary communication by Podwysotszki shortly before his death, Merck is not able to state, as no details of fusing point, formula, or chemical reactions were given by the former. (*M. Bull.*, Jan. 1893.) E. Fischer (*Ber. d. Chem. Ges.*, 1893, 633) confirms the formula $C_8H_{12}O_5$ given by

Merck, as well as the statement that it is a pentatomic alcohol; by oxidation with sodium hypobromite it is changed into *ribose*, $C_5H_{10}O_5$, which treated with sodium amalgam again yields adonite.

According to Cervello and H. A. Hare, adonidin at first slows the action of the frog's heart, increasing at the same time the force of the systole, and finally produces arrest. Hare states that this arrest is diastolic; Cervello, that it is systolic. Both experimenters found that in mammals adonidin increases very markedly the arterial pressure while decreasing the pulse rate, and that after toxic doses the primary rise is followed by a marked fall of arterial pressure, with irregularity of the heart's action. The primary rise of the pressure appears to be chiefly cardiac, although there is some reason for supposing that the drug does exert some influence upon the vasomotor system. The first slowing of the pulse was found by Hare to be due to stimulation of the inhibitory nerves, as it was prevented by their previous section, while finally the fall of pressure was at least in great part owing to the vasomotor palsy.

In 1879 Bubnow introduced adonis vernalis as a very valuable cardiac stimulant, and a number of papers have been published with the general concordant statements that the action of the drug resembles that of digitalis, but that it is more prompt and with less cumulative tendency. It does not appear to be superior to digitalis in diuretic action, and in some cases produces so much vomiting and diarrhoea that it cannot be used (Lublinski and Huchard). In a case reported by Durand, in which three grains (0.2 Gm.) of adonis were given by mistake every half-hour, violent vomiting and diarrhoea were the most troublesome symptoms. Notwithstanding the many favorable reports adonis vernalis does not seem to have come into general use in the treatment of *cardiac dropsies*. The statements of Bechterew, that adonis vernalis is useful in *epilepsy* in conjunction with bromides, is confirmed by Gianni, who found on the other hand that, given by itself, adonis had no influence. The infusion, four to eight parts in one hundred and eighty parts of water, was administered by Bubnow in tablespoonful (15 Cc.) doses every two hours. Durand gives the dose of adonidin as one-third of a grain (0.021 Gm.), repeated at intervals of three or four hours.

Æsculus. *Horse-chestnut*.—This genus, which is generally recognized by botanists as belonging to a natural order of its own, contains about fifteen species, the most famous of which is the true horse-chestnut (*Æsculus Hippocastanum*, L.), said to have been originally a native of Asia, but introduced about the middle of the sixteenth century into Europe, whence it has spread to this country. It is to this species that this article especially applies, though it is probable that any medicinal properties which the tree may have, are shared by the other species of the genus. The fruit or nut abounds in starch, but its bitter, disagreeable taste has prevented its general use as a food, although as long ago as 1856 starch was made from it in France, and recently a pleasant and nutritious article of diet is said to have been prepared by removing its bitter principle by means of alcohol. In the leaves Rochleder found *quercitrin*, and a bitter principle, *esculin*; and in the capsules of the fruit a peculiar acid, *capsulesic acid* (J. P. C., May, 1859; Aug. 1860). (For Rochleder's method of extracting esculin, see U. S. D., 18th edition; for a second process, see

A. J. P., xlv. 400.) Esculin is in shining white, prismatic crystals, inodorous, bitter, but slightly soluble in cold water, more soluble in boiling water, and very readily so in boiling alcohol and in alkaline solutions. Its solution is precipitated by lead subacetate, and its formula, according to Schiff, is $C_{15}H_{16}O_9$. When treated with dilute sulphuric acid, it is converted into grape sugar and a substance called *esculetin*, $C_9H_6O_4$, which is now known to be

nin is found in all parts of the tree, including the leaves as well as the bark and fruit. According to Rochleder, when pure, it is white and soluble in water, alcohol, and ether; becomes red by the absorption of oxygen; colors ferric salts green, but violet on the addition of a little alkali; fluorescent when it is in alkaline solution; in concentrated solution is precipitated, at least partially, by sulphuric, hydrochloric, and metaphosphoric acids, while acetic acid is opposed to this result, and forms also, with potassium and sodium sulphites and ammonium sulphide, precipitates which are readily dissolved by dilute acetic acid. (J. P. C., Jan. 1868, 72.) The powdered kernel of the nut is a sternutatory. The extract of the wood is said to be used in dyeing silk black. The fixed oil, extracted from the kernels by ether, has been employed in France as a topical remedy in *rheumatism*; and the bark as an antiperiodic in doses of half an ounce (16 Gm.) in the twenty-four hours, given in the form of decoction. In the United States a decoction of the leaves is popularly employed for *whooping cough*, and to the seeds themselves, when "carried in the pocket of the patient," is attributed the marvellous property of curing *hemorrhoids*. Esculin has also been successfully administered in *malarial disorders*, in fifteen-grain (1 Gm.) doses repeated once during the intermissions. (Ann. Thér., 1859, 1860.)

The fruit of the *Æsculus Pavia*, L., or *Red Buckeye* of the Southern United States, is said to be an active convulsant. E. C. Batchelor (A. J. P., xlv. 144) found in the cotyledons of the seeds about 2½ per cent. of a peculiar glucoside, *Æsculus glabra*, Willd., the *Ohio Buckeye*, is asserted to be useful in *portal congestion*. (N. P., ii. 21.)

Æthusa. *Æthusa Cynapium*, L.—Poisonous properties have been alternately attributed and denied to this British plant. (See P. J., 1874, 202; Nov., 1880, 438.)

Agaric. *Touchwood. Spunk. Tinder. Fungus laricis. Purging Agaric. Agaric blanco. Agaric purgatif.* Fr. *Larchenschwamm*, G.—The term Agaric is more properly applied to the fungi of the genus Agaricus. *White agaric*, however, or *purging agaric* of medical writers (*agaricus albus*), is referred to *Polyporus officinalis*, Fries (*Boletus Laricis*, Jacquin; *B. purgans*, Persoon), which is found upon the old trunks of the European larch and upon *Larix sibirica*, Ledebour, of Asia. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but, as found in commerce, it is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. That which is most esteemed is said to be brought from Siberia; but it is probably produced wherever the European larch grows. Wm.

M. McPheeters (*St. L. M. S. J.*, x. 421) found a specimen brought from the Rocky Mountains decidedly cathartic in doses of twenty-four grains (1.6 Gm.). An agaric growing on the *Larix leptolepis*, and used in Japan as a sacred medicine under the name of *Toboshi* or *Eburiko*, has been found by Y. Inoko to contain agaric acid. (*Sei-I-Kwai*, April, 1891.) Agaric has a sweetish very bitter taste. Agaric acid, as described by Hofmeister, has the formula $C_{14}H_{27}(OH) \begin{matrix} < COOH \\ < COOH \end{matrix} + H_2O$. The pure acid forms a white, silky, lustrous powder, only slightly soluble in cold water, but moderately soluble in hot water. From this hot solution the acid separates out on cooling in a finely crystalline state. It fuses at $140^\circ C$. ($284^\circ F$). According to J. Schmieder, agaric contains a small amount of a soft resin, $C_{15}H_{20}O_4$, extracted with petroleum benzin, and from 4 to 6 per cent. of a fatty body, which is made up of 1. *agaricol*, $C_{10}H_{16}O$, fusing at $223^\circ C$; 2. *phytosterin*, $C_{26}H_{44}O$; 3. solid hydrocarbons, $C_{23}H_{46}$ and $C_{25}H_{54}$; 4. *cetyl alcohol*, $C_{18}H_{38}OH$; 5. a liquid aromatic alcohol, $C_6H_{14}O$; 6. a fatty acid, $C_{14}H_{24}O_2$; and 7. *ricinoleic acid*, $C_{18}H_{34}O_2$. (Schmidt, *Lehrbuch der Pharm. Chem.*, ii., 3te Auf., 1528.) J. D. Riedel has produced two phenetides of agaric acid, for which antipyretic and anhidrotic properties are claimed. (*Ph. Ztg.*, xvii.)

Medicinal Properties.—The physiological properties of agaric are not well known. In overdose it is said to cause purging. Under the name of *agaricin* an impure alcoholic extract of agaric has been much used, in doses of from one to three grains (0.065–0.2 Gm.) three times a day, against *colliquative sweats*. It is certainly a valuable remedy, free from danger, and effective, although it has some tendency to produce purging. *Agaricin* or *agaric acid* was found by Hofmeister to act upon the lower animals as an anhidrotic, and unless in enormous doses to have little other influence except as an irritant to the gastrointestinal canal. Doses of from one-sixteenth to one-third of a grain (0.0039–0.021 Gm.) were well borne by phthisical patients, and promptly controlled the *night sweats*. (*A. E. P. P.*, xxv.) Köhler, Combemale, Klemperer, and other clinicians have confirmed these results, and it would seem that the acid is one of the most certain remedies of its class, and may be used almost indefinitely without affecting the general system. Dose, from one-third to three-fourths of a grain (0.021–0.048 Gm.), given in pill three times a day. A tincture of the agaric of the Canadian larch has been used successfully in *rheumatism* by J. A. Grant. (*British-Am. Journ.*, April, 1862.) For study of the precipitate found in tincture of *Boletus Laricis*, see *Proc. A. Ph. A.*, 1889, 194.

Thoerner obtained from *Agaricus atramentosus* crystalline, dark-brown scales, which he believed to be *diacetykinon*. (*Ber. d. Chem. Ges.*, 1878, 533.) According to T. L. Phipson, *Agaricus ruber* contains a rose-red coloring matter, *ruberin*, which appears bright blue by transmitted light; being soluble in water, it is washed out of the head of the fungus by a heavy fall of rain. Ether extracts from the fungus a yellowish-white alkaloid, *agarythrine*, which has a bitter, afterwards burning taste, somewhat like aconitine; its chloride is soluble, but the sulphate insoluble in water, the latter dissolving in alcohol; it dissolves in nitric acid with red color, and is colored red by chlorinated lime and afterwards bleached. On agitating

the solution of the alkaloid with ether, it is oxidized by the air to a red coloring matter, which is probably the cause of the red color of the surface of the fungus. (*Chem. News*, 1882, 199.)

Fungus chirurgorum. *Boletus chirurgorum*, *Wundschwamm*, G.—*Surgeon's agaric* is the product of *Polyporus fomentarius* (L.), Fries, which is found upon the oak and beech trees of Europe. It is shaped somewhat like the horse's foot, with a diameter of from six to ten inches. It is soft like velvet when young, but afterwards becomes hard and ligneous. It usually rests immediately upon the bark of the tree, without any supporting foot-stalk. On the upper surface it is smooth, but marked with circular ridges of different colors, more or less brown or blackish; on the under, it is whitish or yellowish, and full of small pores; internally it is fibrous, tough, and of a tawny-brown color. It is composed of short tubular fibres compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting it is August or September. It has neither taste nor odor. Among its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, nitrogenous matter also in small quantity, potassium chloride, and calcium sulphate, and in its ashes are found iron, and calcium and magnesium phosphate. It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting hemorrhage, being applied with pressure. *P. ignarius* (L.), Fries, and *P. marginatus*, Fries, yield similar products.

When prepared polyporus (so-called agaric) is steeped in a solution of nitre, and afterwards dried, it constitutes *spunk*, *punk*, or *tinder*, the *amadou* of the French, which occurs in flat pieces, of a consistence somewhat like that of very soft, rotten buckskin leather, of a brownish-yellow color, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared also from various other species of *Polyporus*, as *P. unguatus*, *P. ribis*, etc.

Agathin. $C_6H_4(OH).CH = N.N(CH_3).C_6H_5$. *Salicyl-a-methyl-phenyl-hydrazine*.—This is obtained by the reaction of salicylic aldehyde upon α -methyl-phenyl-hydrazine. It is a colorless or greenish-white crystalline substance, without odor or taste, is insoluble in water, soluble in alcohol and ether, and melts at $74^\circ C$. It was proposed as a remedy by Israel Roos, and is said by E. Rosenbaum to act like salicylic acid. Although excellent results (see *D. M. Ztg.*, 1892, Nos. 50, 93) have been claimed for it in *neuralgia* and *rheumatism*, without unpleasant effects other than headache, in trials by H. C. Wood it did not seem serviceable. Dose, from eight to ten grains (0.5–0.65 Gm.).

Agave. *Agave americana*, L. *American Agave*. *American Aloe*. *Magwey*. (Fam. *Amaryllidaceae*.)—An evergreen succulent plant, indigenous to Florida, Mexico, and other parts of tropical America, and largely cultivated, chiefly for hedges, in the south of Europe, especially in Spain. Although the *Agave americana* is the best known form, botanists have described of the genus one hundred and fifty species, about one-half of which are indigenous to Mexico, and many of which contribute to the economic products produced in that country from the agave plant. The number of

these products is very great. *Sisal grass* or *sisal hemp* and *Tampico hemp* are the most important of the various fibres obtained from the agave leaves, though a number of other forms are locally known in Mexico. From a number of species of *Agave* are produced in Mexico large quantities of fermented liquors, known as *pulque*, and distilled liquors known as *mescal* or *tequila*. All of the pulque agaves have thick leaves. When they are about to bloom the central bud is cut out, leaving a large cavity into which the sap (*aguamiel* or *honey water*) exudes rapidly. At first clear green, yellowish or whitish, this sap soon by fermentation becomes milky and acquires a cider-like taste or, if the process is allowed to go on, is rapidly converted into vinegar. *Pulque* is said to contain about 7 per cent. of alcohol, and is very largely used as a beverage by the Mexicans, but its odor and taste are disagreeable to unaccustomed palates. The juice has in it an optically inactive reducing sugar, *agavose*, $C_{12}H_{22}O_{11}$. The leaves and roots and stocks of the agave contain saponin and are used in Mexico in the place of soap. The fresh juice is said to be laxative, diuretic, and emmenagogue, and in doses of two fluidounces (60 Cc.) useful in *scurvy*. The leaves are said to be used as counter-irritants, and Lenoble has found in them an acrid volatile oil (*J. P. C.*, xv.). *Agave Gum* has been compared to gum arabic, but differs in containing a much larger proportion of lime, and in being only partially soluble in water, the soluble portions resembling pure gum, but the larger insoluble portions having all the characteristics of bassorin.

Agave virginica, L., which grows in our Southern States, and is known in South Carolina by the name of *rattlesnake's master*, has a very bitter root, which is used, in the form of tincture, in colic. (Robert King Reid, *In. Dis.*, 1849.)

Agelæa. *Agelæa Lamarckii*, Plan.—Under the name of *Cephan-Mah*, *Soandrou*, *Vahé-mainti*, this African plant is used as an anti-blenorrhagic. According to Rochebrune (*Toxicologie Africaine*) it contains a poisonous glucoside, *agelatoxine*.

Ageratum.—*Ageratum conyzoides*, L., a Brazilian plant commonly known in cultivation as *ageratum* (Fam. Compositæ), is said by Barker Smith (*C. D.*, May 15, 1876) to be used as an emmenagogue.

Agopyrin.—This is said to be a mixture of salicin, ammonium chloride, and cinchonine sulphate. It has been exploited as an antipyretic.

Agrimonia. *Agrimonia Eupatoria*, L. *Common Agrimony*. *Herba Agrimonie*. *Aigremoine*, *Eupatoire des Grecs*, Fr. *Odermannig*, *Leberklette*, G. (Fam. Rosaceæ).—This species of *Agrimonia* is a perennial herb, inhabiting Asia, Europe, and North America. Its stem, which rises from one to three feet in height, is hairy, furnished with interruptedly pinnate leaves, and terminated by a long simple spike of yellow flowers. Both the herb and root have been employed. A volatile oil may be obtained from the plant by distillation. *Agrimonia* is a mild astringent. *Dose*, one drachm (3.9 Gm.) or more. (See 16th ed. U. S. D.)

Agurin.—This substance, which consists of five parts of *theobromine-sodium* and two of *sodium acetate*, is a white powder of slightly bitter taste, freely soluble in water. It is alleged that it is less irritant and more actively diuretic than *theobromine*. The powder should be taken in dilute solution in doses of ten to fifteen grains (0.65–1 Gm.) three or four times a day.

Ailanthus. *Ailanthus glandulosus*, Desf. *Tree of Heaven*. *Chinese Sumach*. *Tree of the gods*. *Götterbaum*, G.—This well-known shade-tree belonging to the Fam. Simarubaceæ, in its general aspect and the character of its foliage appears like a gigantic sumach, and was at one time considered to be a *Rhus*. In France it is cultivated for the sake of its leaves, upon which the Chinese silk-worm is fed, and is known by the name of *Japan varnish* (*vernis de Japon*), from its having been mistaken for the true Japan varnish tree, which is a species of *Sumach*. (*P. J.*, vii. 370.) According to Hetet, the bark is an active vermifuge. When in powder it is of a greenish-yellow color, a strong, narcotic, nauseating odor, in its recent state, and of a strongly bitter taste. When chewed, it is said to produce a general uneasiness, a sense of increasing weakness, dazzling, cold sweats, with shivering and a sensation of nausea. It has been found to contain lignin, chlorophyll, a yellow coloring principle, a gelatinous substance (pectin), a bitter substance, an odorous resin, traces of a volatile oil, a nitrogenous fatty matter, and several salts. F. H. Davis detected traces of a crystallizable organic acid, but no alkaloid or glucoside. (*A. J. P.*, 1885, 600.) By the action of alcohol, there is obtained from the bark an *oleoresin* which has the consistence of tar, a very dark greenish-brown color, and in a high degree the odor and taste of the bark. Hetet found the bark to produce in dogs copious stools and the discharge of worms. The resin purged, but rarely acted as an anthelmintic. The vapors of the volatile oil, according to Hetet, cause in man vertigo, cold sweats, and vomiting, though none of the preparations of the bark have that effect when taken internally. The powdered bark has been used successfully against the *tape worm*. *Dose*, from seven to thirty grains (0.45–2.0 Gm.). The oleoresin produces the same effect in a somewhat smaller dose, and keeps better than the bark, which loses its powers with age. (*J. P. C.*, Mars, 1859, 163.) In China the bark is very popular as a remedy in *dysentery* and other bowel complaints. (*A. J. P.*, 1874, 276; *P. J.*, vii. 372.)

In India the bark of the *Ailanthus eweelsa*, Roxb., is used as a bitter tonic. It occurs in rough, dirty-green pieces. Narayan Daji found in it a bitter uncrystallizable principle and a bitter nitrogenous acid, *ailanthic acid*, to which he attributes medicinal virtues. (*P. J.*, Aug. 1870, Oct. 1876, June, 1877.) This acid is not used medicinally in this country.

Aiol. *Bismuth Oxyiodogallate*. $C_6H_2(OH)_3COO(BIOHI)$.—Lüdy describes it as a grayish-green, unirritating, tasteless, and odorless powder which is a basic combination of bismuth, oxygen, iodine, and gallic acid, containing in 100 parts 44.6 parts of bismuth trioxide and 24.3 parts of iodine.

When aiol is brought in contact with surgical secretions it becomes red from the liberation of iodine. According to the researches of Carl S. Haeger (Bruns, *B. k. Ch.*, xv. 1896), it is about as feeble a germicide as is iodoform, but as in the case of iodoform the substances liberated by its decomposition in wounds are actively germicidal. It has been largely used as a local remedy in all cases for which iodoform has been employed, having the superiority over that substance of being nearly free from odor. It does not irritate, but rapidly desiccates ulcerated surfaces. Theoretically, in overdose it should produce symptoms

of both bismuth and iodoform poisoning, but in the only case of poisoning by it which we have found recorded the symptoms of bismuth poisoning followed the injection into the cavity of an abscess of nine and a half fluidrachms (35 Cc.) of its 10 per cent. glycerin solution (Nemmer). Haegler took fifteen grains (1 Gm.) of airol in the course of three days without the production of any disagreeable symptoms. *Brun's Paste*, which has been much used in various skin diseases and ulcerations, is made according to the following formula; airol, one part; mucilage, two parts; glycerin, two parts; argilla alba (kaolin), sufficient to make a soft paste. If the paste becomes too dry, use glycerin; if it be too soft, kaolin may be added. No metal instruments should be employed in preparing the paste, since many metals liberate iodine from airol. For the same reason, no water, only glycerin, should be used in the preparation. The paste is preserved in well-stoppered glass or porcelain jars, which are to be kept closed. (See *Catoplasma Kaolini*, p. 306.)

Injected into the peritoneal cavities of the lower animals in the dose of from one to two grammes per kilo, airol causes clonic convulsions, with coma, nephritis, and fatty degeneration of the liver. It is insoluble in ordinary menstrua, but may be dissolved in alkaline solutions or in diluted mineral acids, and, like iodoform, can be used for the production of antiseptic gauze or other dressings. It may be used as a powder or as a 10 to 20 per cent. salve, which should be prepared with lard or vaseline free from water, since with water, airol undergoes rapid decomposition. The 10 per cent. glycerin solution has been much employed for *tubercular* and other abscesses. It has been used in the form of suppositories made with cacao butter, with alleged excellent results, in *metritis*, *vaginitis*, *rhinitis*, etc., and its emulsion has been injected into cold abscesses.

Ajuga.—Of this genus *A. Chamæpitys* (L.), Schreb., or *Ground Pine*; *A. reptans*, L., *Mountain Bugle*, or *Common Bugle*; and *A. pyramidalis*, L., all of them European species, the last naturalized in America, have been used in medicine, and are probably mild astringents and tonics. The ground pine is said to contain a volatile oil, and has been used to some extent in *amenorrhœa* and in various forms of *rheumatism*, in doses of from one to two drachms (3.9–7.7 Gm.). *Ajuga Iva* (L.), Schreb., of Sardinia, is said to be a depressomotor, an active bactericide, and an antiperiodic. (*A. I. B.*, xxxiv.)

Akazga. *Boudour*, Quai. *Ikaqa*. *Icaya*.—An ordeal poison, largely used in a district on the west coast of Africa, extending far into the interior, north and south of the equator. It occurs in bundles consisting usually of long, slender, crooked stems, with the root generally attached; sometimes of the branches, but seldom of the whole plant. This is about six feet high, with a yellowish-orange bark, in some parts light red, and covered by a gray efflorescence. The leaves are opposite, oval-acuminate, with a linear prolongation at the end more than an inch long. The precise botanical character of the plant is unknown, but it is thought to belong to one of the Loganiaceæ. Thomas R. Fraser found in the plant an alkaloid, *akazgine*. It is colorless, crystallizable with difficulty, soluble in 60 parts of cold absolute alcohol, 16 parts of official alcohol, 130 parts of anhydrous ether, and 13,000 parts of water at 15.5° C. (60° F.). It is freely soluble

in chloroform, carbon disulphide, benzene, and ether of sp. gr. 0.735. The alcoholic extract or the alkaloid acts on the system similarly to nuxvomica. (*Chem. News*, Oct. 18, 1867, 203; see also *A. J. P.*, March, 1867.)

Alangine.—This alkaloid, according to Scheriff, occurs in the bark of the stem and root of *Alangium Lamarckii*, Thwaites (*Karangolum Lam.* (Thwaites), Kze.). It is very bitter, soluble in alcohol, chloroform, and acetic ether, but insoluble in water. In small doses it acts as a febrifuge; in doses of fifty grains (3.2 Gm.) it is emetic.

Alanin Mercury. *Hydrargyri Amidopropionas*. *Hydrargyrum Amidopropionicum*.—Lucca asserts that this compound may be administered internally or subcutaneously, in doses of 0.10 Gm., with great advantage over other antisymphilitics. To prepare "alanin mercury," crystallized amidopropionic acid is dissolved in water, heated to boiling, and mercury added as long as it is dissolved. The filtrate is rapidly evaporated, and the compound then separates in white crystalline needles.

Albargin. *Gelatose Silver*.—This substance, which is a compound of silver and gelatose, is a yellowish bulky powder which, in either cold or warm water, freely forms neutral dialyzable solutions. It contains 15 per cent. of silver. It affects albumin slowly and also precipitates cocaine solutions, but may be used with the alkaloid providing the double solution be freshly prepared at the time of administration. It is not quickly reduced by light, but should be preserved in amber-colored bottles. It was introduced by Bornemann (*Ther. Geg.*, March, 1901) for the treatment of *gonorrhœa*. When there is much irritation, the 1 per cent. aqueous solution may be injected four or five times a day; in more chronic conditions the solution should be 2 per cent.

Alboferine.—A light-brown, odorless, non-hygroscopic and permanent powder, freely dissolving in cold water and possessing a slightly saline taste. Its composition is stated to be as follows: albumin, 90.14 per cent.; iron, 0.68 per cent.; phosphorus, 0.32 per cent.; amido nitrogen, 0.13 per cent., and mineral substances, 9.5 per cent. This preparation has been recommended by a number of German clinicians as a good ferruginous tonic in *anæmia*, *scrofulosis*, *rickets*, and other diseased conditions. *Dose*, for a child, fifteen to forty-five grains (1–3 Gm.); for adults, forty-five to seventy-five grains (3–5 Gm.) a day.

Alchemilla. *Alchemilla vulgaris*, L. *Lady's Mantle*. (Fam. Rosacæa.)—This astringent, bitterish perennial European herb was formerly employed in *diarrhœa*. By the ancients it was highly esteemed; extraordinary powers were ascribed to it by the alchemists. (*P. J.*, 1885, 791.)

Alcornoque.—For an account of this bark, which has long since fallen into entire neglect, see 16th edition U. S. D., p. 1545.

Aldehyde. C_2H_4O . *Acetic Aldehyde*. *Acetaldehyde*. *Aldéhyde acétique (vinique)*, Fr.—Aldehyde is a generic term understood by chemists to apply to a class of bodies holding an intermediate position between the alcohols and the acids derived from them by oxidation. Acetic aldehyde is always meant when the term aldehyde is used by itself. The word means alcohol deprived of hydrogen (*alcohol dehydrogenatum*). (Liebig.) Aldehyde may be prepared in many ways, usually, however, by the oxidation of alcohol in some form. W. and R. Rodgers (*J. P. C.*, 40, 248) give the following: 1 part of alcohol

sp. gr. 0.842, and 1 part of potassium dichromate, are introduced into a large tubulated retort, and $1\frac{1}{2}$ parts of sulphuric acid dropped in through the tubulure. Sufficient heat is evolved to start the distillation, but heat must be applied to towards the end. The distillate is slightly contaminated with acetic acid. If the aldehyde be desired pure, the distillate is to be mixed with twice its volume of ether, surrounded with cold water, and dry ammoniacal gas passed in to saturation. Aldehyde-ammonia crystallizes out. This is to be decomposed in a retort by a mixture of 3 parts of sulphuric acid and 4 parts of water, and the distillate rectified and dried by contact with calcium chloride. Aldehyde is a colorless, mobile, inflammable liquid, having a decidedly pungent, ethereal, and suffocating odor. Its sp. gr. is 0.790, and boiling point 22° C. (71.6° F.). It mixes in all proportions with water, alcohol, and ether, and is rapidly converted into acetic acid on exposure to the air, through absorption of oxygen. It possesses very marked anti-putrescent properties, meat being preserved for months by its 2 per cent. aqueous solution. The intoxication caused by it in animals is characterized by a very great loss of sensibility. It appears to paralyze the vagi, although its cardiac action is comparatively feeble. Upon the respiration it exerts a most powerful influence, in small doses quickening it, in large doses depressing it. The temperature is much diminished. Applied locally aldehyde is very irritating. (M. T. G., Sept. 1875.)

Iodide aldehyde may be made by mixing together iodine, iodic acid, and a solution of aldehyde and separating by adding water. (See paper by P. Chautard, P. J., 1886, 224.)

Alettris. *Alettris farinosa*, L. *Star Grass*. *Blazing Star*. *Mealy Starwort*. *Colio Root*. *Alétris farineux*, Fr. *Mehlige Alettris*, G. (Fam. Liliacæ.)—An indigenous perennial plant, the leaves of which spring immediately from the root, and spread on the ground in the form of a star. The root, which was formerly included in the U. S. secondary list, is small, crooked, branched, blackish externally, brown within, and intensely bitter. The bitterness is extracted by alcohol, and the tincture becomes turbid upon the addition of water. The decoction is moderately bitter, but much less so than the tincture. It affords no precipitate with the salts of iron. (Bigelow.) In small doses of about ten grains (0.65 Gm.) it appears to be a simple bitter tonic. In very large doses it is said to be cathartic and emetic. It has been employed, with asserted benefit, in *colio*, *dropsy*, and *chronic rheumatism*. *Alettrin*, a resinoid, is prepared by exhausting the drug with alcohol and evaporating the percolate to dryness, treating with water, and drying the residue. It is asserted to be a *uterine stimulant* in doses of from one to two grains (0.065–0.13 Gm.).

Algarobilla, the pod of *Balsamocarpon brevifolium*, Clos., *Cæsalpinia brevifolia*, Baill. (Fam. Leguminosæ), a drug containing over 60 per cent. of tannin and a quantity of *ellagic acid*, is obtained from Chili. (Gehe's Report, N. R., 1878, 332; J. Chem. S., 1891, 918.)

Alisma. *Alisma Plantago-aquatica*, L. *Water Plantain*. *Plantain d'eau*. *Pain de grenouilles*, Fr. *Froschlöffel*, *Wasservegerich*, G. (Fam. Alismacæ.)—A perennial herbaceous plant, common to Asia, Europe, and the United States. The root has when fresh an odor like that of Florentine orris, but loses it when dried. Its

taste is acrid and nauseous. It contains a pungent volatile oil and an acrid resin, to which all its virtues must be ascribed. The Calmucks in Russia are said to use it for food. The leaves are rubefacient, and will sometimes even blister. They have been recommended in *gravel* and *cystitis*. *Dose*, a drachm (3.9 Gm.).

Alkanet. *Alkanna*. *Orcanette*, Fr. *Alkanna-wurzel*, G.—This is the root of *Alkanna tinctoria* (L.), Tausch (*Anchusa tinctoria*, L.), or *dyers' alkanet*, an herbaceous perennial plant, of the Fam. Boraginacæ, growing in the Grecian Archipelago and the south of Europe, where it is cultivated. See E. M. Holmes, P. J., 1897, p. 61. For an account of Syrian alkanet and allied plants, see *Proc. A. Ph. A.*, 1896, 565. Alkanet, as found in commerce, is in pieces three or four inches long, from the thickness of a quill to that of the little finger, somewhat twisted, consisting of a dark red, easily separable bark, and an internal ligneous portion, which is reddish externally, whitish near the centre, and composed of numerous distinct, slender, cohering fibres. As it comes to us it is usually much decayed internally, very light, and of a loose, almost spongy texture. The fresh root has a faint odor, and a bitterish, astringent taste; but when dried it is nearly inodorous and insipid. Its coloring principle, which abounds mostly in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a deep red color, but is insoluble in water. It may be obtained by first exhausting the root with water, and then treating it with a weak solution of potassium or sodium carbonate, from which the coloring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses acid properties, forming with the alkalis and earths neutral compounds, which are of a blue color, and soluble in alcohol and ether. Its weak acid character resembles that of alizarin, to which it is chemically related, as when distilled with zinc dust it yields *methyl-anthracene*. It has also received the names of *anchusin* and *alkannin*. The *anchusin* has been extracted and studied by C. J. S. Thompson. (A. J. P., 1886, 409.) He finds it to vary in amount between 5.25 and 6.02 per cent. It is red, resin-like, insoluble in water, soluble in oils, alcohol, chloroform, and ether, and with a rich deep blue color in alkali hydroxides, the color changing again to crimson on addition of an acid. According to A. Gawalowski, the red coloring matter of alkanet root consists of two distinct bodies, the one turning blue, the other green by the action of alkalis. The first of these, *alkanic acid*, is extracted by ether and alcohol. The second, *anchusio acid*, is obtained by extraction with benzene. Both form characteristic colored salts. (Ph. Ztg., 1902, 817.) Alkanet is somewhat astringent, and was formerly used in several diseases; but it is now employed exclusively for coloring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. The best way to use it with this object in view is to suspend the alkanet, after tying it in a piece of flannel, in the melted fat. It is said also to be used in the preparation of spurious port wine.

Allamanda. *Allamanda cathartica*, L., is a shrub of the Fam. Apocynacæ, growing in Porto Rico, the extract of whose bark is said to be an excellent hydragogue cathartic, in doses of from one to two grains (0.065–0.13 Gm.).

Alliaria. *Alliaria officinalis*, Andr. *Sisymbrium Alliaria*, Scop. *Erysimum Alliaria*, L.

Alliaria Alliaria (L.), Brit. *Hedge Garlic*.—A perennial European herb, a native also of Northern Asia, and naturalized from Canada to Virginia, having an alliaceous odor when rubbed, and a bitterish, somewhat acrid taste. When eaten it communicates its odor to the breath. Wertheim obtained from the root a volatile oil, apparently identical with that of mustard. (*Ann. Ch. Ph.*, liii. 52.) The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and are used as external applications in *gangrenous affections*, and to promote *suppuration*.

Allium. U. S. 1890. *Garlic*. *English Garlic*. The genus *Allium* includes a large number of species, of which nearly seventy are indigenous in this country. Many, and perhaps all, of these species contain volatile oil upon which their activity depends. The cultivated garlic, of which the bulbs were formerly recognized in the U. S. Pharmacopœia, is *Allium sativum*, L., for which, according to Griffith, *A. canadense*, L., has been substituted and found efficient.

Allium sativum, L., is a perennial plant with numerous bulbs which have a common membranous covering, from the base of which the fibres that constitute the proper root descend. The stem is simple, and rises about two feet. The leaves are long, flat, and grass-like, and sheathe the lower half of the stem. At the termination of the stem is a cluster of flowers and bulbs mingled together, and enclosed in a pointed spathe, which opens on one side and withers. The flowers are small and white, and make their appearance in July. This species of garlic grows wild in Sicily, Italy, and the south of France. The bulbs, or so-called cloves, are usually six or eight in number, oblong or wedge-shaped, and covered with dry membranous scales, with a pungent odor and a disagreeable and acrid taste. The U. S. Pharmacopœia 1890 directed that they should be used without having been dried. The oil of garlic is of a dark brownish-yellow color, heavier than water, and decomposed at its boiling temperature. It may be purified by repeated distillation in a salt water bath, and is then lighter than water, of a pale yellow color, and not decomposed by boiling. Semmler obtained from garlic bulbs 0.09 per cent. of the volatile oil, sp. gr. at 14.5° C. (58° F.) 1.0525; it was yellow, having an intense odor and optically inactive. By fractional distillation he obtained four products, $C_6H_{12}S_2$, $C_6H_{10}S_2$, $C_6H_{10}S_3$ and $C_6H_{10}S_4$, which decomposed during distillation, and hence could only be obtained by distillation in vacuo. The oil, according to Semmler, is free from allyl sulphide, the latter having the sp. gr. 0.8991. (*A. Pharm.*, 1892, p. 434.) The impure oil has an exceedingly pungent odor and a strong acrid taste, and, when applied to the skin, produces much irritation and sometimes even blisters. The pure oil combines with silver nitrate, forming a precipitate soluble in heated alcohol and afterwards separating in crystals. Besides this oil, fresh garlic, according to Cadet de Gassicourt, contains, in 1406 parts, 520 of mucilage, 37 of albumen, 48 of fibrous matter, and 801 of water. Bouillon-Lagrange mentions among its constituents sulphur, a saccharine matter, and a small quantity of fecula. The fresh bulbs yield upon pressure nearly a fourth part of juice, which is highly viscid, and so tenacious as to require dilution with water before it can be easily filtered. When dried, it serves as a lute for porcelain. It has the medicinal properties of the bulbs. Water, alcohol, and vinegar extract the virtues of garlic.

Protracted boiling renders it inert. According to Semmler (*A. Pharm.*, 1887, p. 927), *Allium ursinum* contains a volatile oil which consists mainly of vinyl-sulphide, C_4H_6S or $(C_2H_5)_2S$.

Medicinal Properties and Uses.—The use of garlic as a medicine and as a condiment can be traced to earliest antiquity. When taken internally, and even when applied externally, the oil is absorbed and imparts its odor to the breath, urine, perspiration, etc. The oil of garlic has some influence upon the human system as a general mild stimulant. Its chief value in medicine is for its local action upon the stomach and as a stimulant expectorant. The garlic itself is sometimes employed as a rubefacient which, by yielding its volatile oil to absorption, stimulates the nervous system, especially in the case of young children. The oil may often be given with great advantage in *chronic bronchitis* and in the advanced stages of *obstinate acute bronchitis*. It is especially valuable in the treatment of children when there is a distinct nervous element. In *catarrhal pneumonia* of young children the bruised garlic cloves are often applied as a poultice to the lungs, and similar applications were formerly used upon the feet for the *nervous restlessness* or even the *convulsions* of young children. Garlic clove may be swallowed either whole or cut into pieces of a convenient size, but the syrup has replaced most other methods of administration. The dose in substance is from half a drachm to two drachms (2–7.7 Gm.) of the fresh bulb. That of the juice is half a fluidrachm (1.8 Cc.).

Syrupus Allii. U. S. 1890, was prepared according to the following formula: "Fresh Garlic, sliced and bruised, *two hundred grammes* [or 7 ounces av., 24 grains]; Sugar, *eight hundred grammes* [or 28 ounces av., 96 grains]; Diluted Acetic Acid, a *sufficient quantity*, to make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Macerate the Garlic with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Diluted Acetic Acid during four days, and express the liquid, avoiding the use of metallic utensils. Then mix the residue with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] more of Diluted Acetic Acid, and again express. Mix the expressed liquids, and filter. Pour the filtrate upon the Sugar, contained in a suitable vessel, and stir or agitate until the Sugar is dissolved. Lastly, add enough Diluted Acetic Acid to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms], and mix thoroughly. Keep the Syrup in well-stoppered, completely filled bottles, in a cool place. *Syrup of Garlic* may also be prepared in the following manner: Prepare a percolator or funnel in the manner described under Syrup (see *Syrupus*); pour the filtrate obtained as directed in the preceding formula upon the Sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it by Diluted Acetic Acid, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." U. S. 1890.

This preparation is made upon correct principles, as vinegar is a better solvent of the active matter of garlic than water. The syrup is given in *chronic bronchitis* and the advanced stages of *acute bronchitis* of the lungs, and is particularly beneficial in infantile cases. A teaspoonful (3.75 Cc.) may be given for a dose to a child a year old.

Allyl Tribromide. $C_3H_5Br_3$. *Tribromhydrin*. This incorrectly named substance is a colorless or faintly yellowish liquid at the ordinary temperature, but solidifying when cooled below $10^\circ C$. ($50^\circ F$.) to a mass having a specific gravity of 2.430, which has been used with alleged good results in *hysteria* and *asthma*, given in capsules containing each five drops (0.25 Cc.). (*Ph. Post*, Dec. 1888.)

Alnus.—Of this genus of small trees or bushes, *A. glutinosa* (L.), *Medic.*, *Common European Alder*, *Black Alder*; *A. rugosa* (Du Roi), K. Koch (*A. serrulata*, Willd.), or *American Alder*; *A. incana* (L.), Willd., or *Tag Alder*, are tonic and astringent, and have been used in intermittent fever, the bark being the part employed. *A. glutinosa*, or "*The European Alder*," has been used for dyeing and also for tanning. According to Eitner, the bark contains from 16 to 20 per cent. of tannic acid. (Gerber, 1878, 85 and 124.) The tannic acid, however, appears to differ from that of galls and oak bark, as, according to Stenhouse, it does not yield glucose when acted on by sulphuric acid. (*P. J.*, Dec. 1861.) F. Dreykorn and E. Reichardt, however, state that it is resolved by sulphuric acid into *alnine red* and sugar. (*A. J. P.*, xlii. 403.)

Alphol.—*Salicylic Ether of Alpha-naphthol*, $C_6H_4\left\{\begin{smallmatrix} OH \\ COOC_{10}H_7 \end{smallmatrix}\right.$, is obtained by reaction between salicylic acid and alpha-naphthol. It is a white, crystalline powder, melting at $83^\circ C$. ($181.4^\circ F$.). Soluble in alcohol, ether, and fixed oils; insoluble in water. Used as an antiseptic and antirheumatic. *Dose*, eight to fifteen grains (0.5–1.0 Gm.).

Alstonia. *Br. Add.* *Echites*.—Under *Alstonia* the *Br. Add.* recognizes the dried barks of *Alstonia scholaris* (L.), R. Br. (*Echites scholaris*, L.), of India and the Philippine Islands, and *Alstonia constricta*, F. Muell., of Australia, two apocynaceous trees whose barks are quite dissimilar in appearance, and, as far as our present knowledge goes, contain different alkaloids. These barks are respectively described as follows: "The bark of *Alstonia scholaris* is usually in irregular fragments one-eighth to half an inch (three to twelve millimetres) thick, of a somewhat spongy texture and a short, coarse fracture; the external layer is unevenly rough and fissured and of a brownish-gray color with occasional blackish spots, the internal layer bright buff. A transverse section shows the inner layer to be finely marked with numerous small medullary rays. Almost without odor. When chewed it develops a bitter taste. The bark of *Alstonia constricta* is usually in curved pieces or quills which may have a width of two and a half inches (sixty-four millimetres) or more, and a thickness of half an inch (twelve millimetres). It is covered with a thick periderm varying from one-tenth of an inch to one-fourth of an inch (two and a half to six millimetres) in thickness; of a rusty-brown color, strongly rugose, and marked with large, deeply-fissured reticulations; it sometimes bears small white foliaceous lichens. Internally the bark is of a cinnamon-brown color, and is marked with strong, coarse longitudinal striae. On transverse section the bark exhibits the dark brown periderm covering the inner orange-brown tissues, in which may be observed, with a lens, numerous small shining particles. The fracture is short and granular in the outer layers, but fibrous in the liber portion. It has a faint aromatic odor and a very bitter taste." *Br. Add.*

From the bark of *Alstonia scholaris*, *dita bark*, M. Gruppe extracted an uncrystallizable, hygroscopic, bitter principle, *ditaine*. (*J. P. C.*, 4e sér., xviii. 225; xix. 84; *P. J.*, Aug. 1875.) Harnack (*Ber. d. Chem. Ges.*, 1878) first obtained ditaine in pure crystallized form, and gave it the formula $C_{20}H_{30}N_2O_4$. According to Erich Harnack (*Ditaine*, Leipsic, 1877), ditaine in the frog acts as a paralyzant upon the motor nerve centres and the motor nerve trunks, and also upon the vagi. Upon mammals its influence resembles closely that of curare. The peripheral nerve endings are paralyzed by it, as are also the peripheral vagi and the vasomotor nerves. O. Hesse (*P. J.*, Oct. 23, 1880) finds in dita the following principles. Three alkaloids: *ditamine*, $C_{16}H_{10}NO_2$, the relative amount of which he estimates at 0.04 per cent.; *echitamine*, $C_{22}H_{28}N_2O_4 + H_2O$ (identical, according to Hesse, with Harnack's ditaine); and *echitenine*, $C_{20}H_{27}NO_4$. Of these, the second is the strongest base, and resembles ammonia in its chemical characters. Hesse considers the compound given above with one molecule of water as the hydroxide of a strong basic radical, *echitammonium*, $C_{22}H_{29}N_2O_4$. The solutions of *echitammonium hydroxide* are so strongly basic that they precipitate the hydroxides of copper, iron, aluminum, and lead, and decompose sodium and potassium chlorides, liberating the corresponding hydroxides. Hesse considers echitammonium the most strongly basic of all the alkaloids. Hesse also obtained by extraction with petroleum benzin *echiacoutchin*, *echiretin*, *echicerin*, *echitin*, and *echitein*, of which the three last mentioned are crystalline. (*See A. J. P.*, 1895, 166.)

From *Alstonia constricta*, F. V. Müller and A. Rummel obtained *alstonine*. Oberlin and Schlagdenhauffen found in 1879 another alkaloid, *alstonicine*. Hesse subsequently analyzed the bark and found alstonine, the *chlorogenine* of a former investigation, which has the composition $C_{21}H_{20}N_2O_4$, *porphyrine*, $C_{21}H_{25}N_3O_2$, and *alstonidine*. The alkaloids and their salts in acidulated solutions show decided blue fluorescence.

The bark of *Alstonia scholaris* is used as a bitter tonic and as an antiperiodic. Ditaine, probably impure, has been employed with alleged most excellent results in the malarial fever of the Philippines, given in doses of one drachm (3.9 Gm.). (*See Proc. A. Ph. A.*, 1877.) Under the name of the *Australian Fever Bark*, or *Bitter Bark*, the bark of *Alstonia constricta* is said to be largely employed in the treatment of fevers in the Australian colonies.

The *Br. Add.* recognizes an *infusion* (*Infusum Alstoniæ*, *Br. Add.*), one ounce to a pint; *dose*, one-half to one fluidounce (15–30 Cc.); also a *tincture* (*Tinctura Alstoniæ*, *Br. Add.*, 8 per cent.); *dose*, one-half to one fluidrachm (1.8–3.75 Cc.).

Aluminum Acetate as well as the *subacetate* has been employed to some extent in medicine as a substitute for the sulphate. The deliquescent acetate may be made by the direct combination of hydrated alumina with acetic acid or by reaction between aluminum sulphate and lead acetate,

Alsol, a 50 per cent. aqueous solution of aluminum aceto-tartrate, has been patented. It is used as a gargle. (*Ph. Era*, 1898, 362.)

Aluminum and Iron Sulphate. *Ferroso-Aluminic Sulphate*. *Sulphate of Aluminum and Iron*. $AlFe(SO_4)_2 \cdot 12H_2O$.—This double salt was

brought forward by Sir James Murray of Dublin, as an astringent, styptic, and vermifuge. His method of preparing it is not very clearly expressed, but it may be presumed to be formed by dissolving alumina and ferrous carbonate, both recently precipitated, in sulphuric acid, and duly evaporating the solution. Klauer states that it is produced in crystalline tufts when a solution of the component salts mixed with an excess of sulphuric acid is left to stand in a warm place. (*Watt's Dict.*, vol. v. 583.) Murray recommended it in chronic dysentery, diarrhoea, *fluor albus*, and the *colliquative sweats* and *diarrhoea* which attend *hectic fever* and *consumption*. Externally he found it a powerful styptic, useful as a gargle in *relaxation of the tonsils and uvula*, and in *salivation*, as an injection in *hemorrhages*, and as a wash for foul and flabby ulcers. Dose, from five to ten grains (0.32–0.65 Gm.), dissolved in some aromatic water.

Aluminum Boroformate occurs in lustrous crystals, and may be prepared by introducing freshly precipitated alumina into a mixture of two parts of formic acid, one part of boric acid, and seven parts of water. The solution is evaporated and crystallized. (*Ph. Rund.*, 1894, 256.)

Aluminum Caseinate.—A yellowish-white, tasteless powder containing five per cent. of aluminum; insoluble in water, sparingly dissolved when macerated in saliva, and yielding aluminum to dilute acids. It was introduced by Rud. Meyer (*Ap. Ztg.*, Sept. 23, 1899, 566) as a remedy in *intestinal catarrh*, given in doses of four to five grains (0.26–0.32 Gm.). It is prepared as follows: Milk, freed from albumin by repeated heating to 62° C. (143.6° F.), and straining, and then sterilized, is precipitated with solution of aluminum acetate (*liquor aluminium acetici*); the precipitate is washed completely with water, and after removing the water with alcohol, deprived of fat by means of ether. The product is dried at a moderate temperature, and while drying powdered.

Even the soluble salts of aluminum have very little influence upon the general organism, but Siem (*Ueber die Wirkung des Aluminiums und des Berylliums auf den thier. Organismus*, Dorpat, 1886) has shown that the *aluminum* and *sodium lactate* or *tartrate*, given in sufficient doses, will produce in frogs and also in mammals a centric general muscular relaxation, deepening into a complete loss of reflex excitability, and general paralysis. When administered in continuous doses for a series of days, these salts cause in the lower animals loss of appetite, constipation, depression, lessening of general sensibility, pronounced apathy with great weakness, ending commonly in paralysis, with convulsive tremblings, fall of temperature, stupor, and death, which sometimes occurs in the midst of tetanic convulsions, more usually through an almost imperceptible diminution of the respiratory movement. These results have been confirmed by Döllken (*A. E. P. P.*, Bd. xl., 1897), who finds the symptoms to be due to an action exerted upon the nerve centres, with demonstrable anatomical changes in the ganglionic cells.

Alummol. *Aluminum beta-naphthol-disulphonate*.—A whitish, non-hygroscopic powder, easily soluble in cold water and glycerin, slightly soluble in alcohol, which has been locally used as a powerful astringent, desiccant, and antiseptic. Its aqueous solution has a slight bluish fluorescence, feeble acid reaction, and is colored blue by iron chloride. The solution of 40 per cent. is

made with hot water and remains clear on cooling. Its aqueous solutions are incompatible with alkalies and ammonia. Though it coagulates albumin, it is said to be dissolved in an excess of albumin, and, therefore, to be able to reach deep recesses of wounds. It has been strongly recommended in nasal, urethral, and other catarrhal inflammations. The strength of the solution employed varies from 1 per cent. in *gonorrhoea* to 10 per cent. in *abscesses*. (See B. K. W., 1892; *Dermatologen-Congress zu Wien*, 1892; *Th. M.*, 1892, 644.) Two to ten parts of alummol mixed with ten parts of starch, has been used by insufflation in cases of laryngitis. Alummol, however, would appear to be very feeble and slowly acting as a germicide, a 1 per cent. solution requiring twenty-four hours to destroy bacilli of anthrax. As a surgical dressing from 1 to 2 per cent. solution may be used. In *infected wounds* the caustic 20 per cent. solution is employed. In diseases of the skin alummol is used with talc or starch as a powder, or with lanolin as an ointment, the strength varying from 2 to 20 per cent.

Amanita.—Of the fungus genus *Amanita*, some species, such as *A. caesarea*, are edible, while many others are violently poisonous. Among these may be mentioned the *A. phalloides*, Fries, or *skunk mushroom*, and the *A. muscaria* (L.), Pers., or *fly fungus*. The most characteristic symptom of poisoning by the former is the saffron color of the urine, deepening as the poisoning progresses into purple; the symptoms otherwise resembling those caused by the more notorious *A. muscaria*, which has been employed from time immemorial by the Tartars as a means of producing intoxication. *A. pantherina*, used in Japan as a fly poison, is said to be exceedingly active. According to Inoko, it contains 1 per cent. of a mixture of alkaloids, the greater part of which is *choline* and the rest *muscarine*. It grows chiefly in woods and under trees, and is variable in color, being found scarlet, carmine, orange, greenish yellow, pale brown, and even white in hue. The pileus, which is often seven or eight inches in diameter, is covered with whitish, angular warts or spongy scales, which when moist are viscid. When growing it is convex, but becomes flat or depressed when it has attained its full size; the stem is not so solid as that of the mushroom, and is bulbous below, and covered at the base with scales. The gills are white and broad.

The active principles of probably all poisonous species of *amanita* are *choline* and *muscarine*, $C_5H_{15}NO_3$. According to S. Pouchet the toxicity of *muscarine* is greatly increased by certain albuminoids contained in the fly agaric, though these albuminoids themselves are not poisonous. (*B. G. T.*, p. cxxvii.)

Muscarine was first obtained by Schmiedeberg and Koppe in a state of purity. (*Das Muscarin*, Leipzig, 1869.) The alkaloid may be produced artificially by gently heating *choline platinochloride* with strong nitric acid. Potassium chloride is used to decompose the *muscarine platinochloride* and produce *muscarine hydrochloride*; treatment with moist silver oxide yields the *muscarine* as a hydrate ($C_5H_{15}NO_3 \cdot H_2O$). *Muscarine* resembles *physostigmine* somewhat in its physiological action, and is antagonistic to *atropine*, producing free salivation and weeping, vomiting, diminution of the force and frequency of the pulse, dyspnea, great muscular weakness deepening into paralysis and finally death, usually by arrest of respiration. The pupil is intensely contracted,

but dilates before death. The diastole of the heart is very much prolonged, and after very large doses diastolic arrest occurs. This is due to an action upon the inhibitory nerves, and if atropine be given so as to paralyze them the cardiac movements re-occur. The vasomotor nerves are said to be paralyzed. The action on the abdominal viscera is very marked. The muscles of the intestines, bladder, and spleen are tetanically contracted. Thus the intestines are transformed into hard white cords, or afterwards, becoming somewhat relaxed, exhibit a tumultuous peristalsis. The abdominal secretions are greatly increased. Most of the physiological results obtained by Schmiedeberg and Koppe have been confirmed by J. L. Prevost. (*J. P. C.*, 4e sér., xx. 385; *Congrès Méd. Internat.*, Geneva, 1878. See also A. E. P. P., xxxi.)

Amber. *Succinum.* *Ambre, Succin*, Fr. *Bernstein*, G.—Amber is a fossil resin, occurring generally in small detached masses, in alluvial deposits, in different parts of the world. According to Goefert, there are about fifty species of extinct coniferous trees of which amber represents the resinous exudation. It is found chiefly in Prussia, either on the seashore, where it is thrown up by the Baltic, or underneath the surface. Large deposits occur in some lakes on the eastern coast of Courland, and an extensive bed of yellow amber was discovered in 1854, on sinking a well in the coal mines near Prague. The largest mass of amber yet found weighed thirteen pounds. Amber also occurs in considerable quantities near Catania, in Sicily. It is usually associated with lignite, and sometimes encloses insects and parts of vegetables. In the United States, it was found at Cape Sable, Maryland, by Troost. In this locality it is associated with lignite and iron pyrites. It has also been discovered in New Jersey. The amber consumed in this country is brought from the ports of the Baltic. A mine of it is said to have been discovered near Rockwood in Australia.

It is a brittle solid, generally in small irregular masses, permanent in the air, having a homogeneous texture and vitreous fracture, and susceptible of a fine polish. It becomes negatively electric by friction. Its color is generally brownish yellow, either light or deep, but is occasionally reddish brown or bluish from staining with ferric phosphate. It has no taste, and is inodorous when cold, but exhales a peculiar, aromatic odor when heated. It is usually translucent, though occasionally transparent or opaque. Its sp. gr. is about 1.07. Water and alcohol scarcely act on it. When heated in the open air, it softens, melts at 286.7° C. (548° F.), swells, and at last inflames, leaving, after combustion, a small portion of ashes. Subjected to distillation in a retort furnished with a tubulated receiver, it yields, first, a yellow acid liquor, and afterwards a thin yellowish oil, with a yellow waxy substance, which is deposited in the neck of the retort and the upper part of the receiver. This waxy substance exhausted by cold ether of the part soluble in that menstruum, is reduced to a yellow micaceous matter, identical with the *chrysen* of Laurent. A white crystalline substance, identical with the *idrialin* of Dumas, may be separated from the micaceous substance by boiling alcohol. Both *chrysen* and *idrialin* are hydrocarbons. (Pelletier and Walter, *J. P. C.*, v. 60.) As the distillation proceeds, a considerable quantity of combustible gas is given off, which must be allowed to escape. By continuing the

heat, the oil gradually deepens in color, until, towards the end of the distillation, it becomes black and of the consistence of pitch. The oil obtained is called *oil of amber*, and the acid liquor is a solution of impure *succinic acid*. Repeatedly distilled from nitric acid, amber yields an acid liquor, from which, after it has been neutralized with potassium hydroxide, ether separates pure camphor. (Doepping, *J. P. C.*, vi. 168.) Borneol is also obtained by distilling to dryness powdered amber with an extremely concentrated solution of potassium hydroxide (G. Reich, *Ibid.*, xiii. 33).

Tschirch (*Harze und Harzbehälter*, 278) has made within recent years a careful study of amber. He finds the main constituents to be a *succinobietic ether of borneol*, which is extracted by prolonged treatment with alcohol, and amounts to 30 per cent. of the amber, and the *succinic ester of succinoresinol*, which is insoluble in alcohol and makes up 70 per cent. of the amber. This latter compound holds a small amount of sulphur (about 0.47 per cent.).

Amber was held in high estimation by the ancients as a medicine, but at present is never so used. The oil of amber is an empyreumatic product which is prepared by destructive distillation of amber. The heat requisite for the complete decomposition of amber cannot be supported by a glass retort; and, in order that all the oil which it is capable of yielding may be collected, the distillation should be performed in a tubulated iron or earthenware retort, which may be placed immediately upon the fire; sand is added to prevent the amber from swelling too much. The oil may be separated from the acid liquor by means of the separating funnel. As first procured, it is a thick, very dark-colored liquid, of a peculiar, strong, empyreumatic odor. In this state it is occasionally employed as a liniment, but for internal use it should be rectified. It has the composition $C_{10}H_{12}$. It is almost impossible to procure pure oil of amber in commerce.

The U. S. Pharmacopœia of 1870, under the name of *Oleum Succini Rectificatum*, or *Rectified Oil of Amber*, gave the following process. "Take of Oil of Amber a pint; Water *six* pints. Mix them in a glass retort, and distil until four pints of Water have passed with the Oil into the receiver; then separate the Oil from the Water, and keep it in a well-stopped bottle." U. S. 1870.

By successive distillations oil of amber becomes thinner and more limpid, till at length it is obtained colorless. The first portions which distil are less colored than those which follow, and may be separated for keeping, while the remainder is submitted to another distillation. For practical purposes, however, the oil is sufficiently pure when once redistilled. As usually found in commerce, the rectified oil is of a light yellowish-brown or amber color. As first distilled it has an amber color, sp. gr. 0.903 at 15.6° C. (60° F.), and a boiling point from 170.5°–186.1° C. (339°–367° F.). (Ebert.) When quite pure it is said to be colorless, as fluid as alcohol, of the sp. gr. 0.758 at 23.8° C. (75° F.), and to boil at 85.5° C. (186° F.). It has a strong, peculiar, unpleasant odor, and a hot acid taste. It imparts these properties in some degree to water, without being perceptibly dissolved. It is soluble in eight parts of alcohol of the sp. gr. 0.847, in five parts of the sp. gr. 0.825, and in all proportions in absolute alcohol, ether, chloroform, carbon disulphide, and the fixed oils. (Ebert.) On exposure to light

and air, it slowly changes in color and consistence, becoming ultimately black and solid. It appears, when quite pure, to be a hydrocarbon of the terpene class. It is said to be sometimes adulterated with oil of turpentine, which may be detected by passing hydrochloric acid gas through the suspected oil. If pure it will remain wholly liquid; while oil of turpentine, if present, will give rise to the formation of solid artificial camphor. (*P. J.*, xiii. 292.) It was officially described as "a colorless or pale yellow, thin liquid, becoming darker and thicker by age and exposure to air, having an empyreumatic, balsamic odor, a warm, acrid taste, and a neutral or faintly acid reaction. Sp. gr. about 0.920. It is readily soluble in alcohol. When mixed with fuming nitric acid, it acquires a red color, and, after some time, is almost wholly converted into a brown, resinous mass of a peculiar musk-like odor." *U. S.* 1870.

Rectified oil of amber is stimulant and antispasmodic, and occasionally promotes the secretions, particularly that of urine. It has been employed with advantage in *amenorrhœa*, *hysteria*, and *whooping cough*. The dose is from five to fifteen minims (0.3–0.9 Cc.), diffused in some aromatic water by means of sugar and gum arabic. Externally applied the oil is rubefacient, and is considerably used as a liniment in *chronic rheumatism*, and in certain spasmodic disorders, as *whooping cough* and *infantile convulsions*. In the latter affection it should be rubbed along the spine.

Ambergris. *Ambra grisea* (cinerea). *Ambre*, *Ambre gris*, Fr. *Ambre*, *Graue Ambra*, G.—This substance, which is found floating on the sea, particularly in the southern hemisphere, is now generally believed to be produced in the intestines of the *Physeter macrocephalus*, L., or *spermaceti whale*. It is in roundish or amorphous pieces, usually small, but sometimes weighing as much as 50, 100, or even 200 pounds. These pieces are often composed of concentric layers. They are of various colors, usually gray, with brownish, yellow, and white streaks, often dark brown or blackish on the external surface. They are opaque, lighter than water, and of a consistence like that of wax. Ambergris has a peculiar aromatic agreeable odor, is almost tasteless, softens with the warmth of the hand, melts under 100° C. (212° F.), is almost completely volatilizable by heat, and is inflammable. It is insoluble in water, but is readily dissolved, with the aid of heat, by alcohol, ether, and the volatile and fixed oils. It consists chiefly of a peculiar fatty matter analogous to cholesterol, and denominated by Pelletier and Caventou *ambrein*. This may be obtained by treating ambergris with heated alcohol, filtering the solution, and allowing it to stand. Crystals of ambrein are deposited. It is incapable of forming soaps with the alkalis. When pure it has little or no odor. Beaugard and Gouchet believe that ambergris is a calculus composed of crystals of *ambrene* mixed with black pigment and star-coral debris. When fresh it is soft in consistence and disagreeable in odor. If kept for a year or two in air tight containers it loses its excrementitious odor and acquires the characteristic perfume for which it is valued. This change Beaugard believes is due to a microbe (*Spirillum recti physeteris*). (*C. R. A. S.*, cxxv. 254.) Ambergris is very frequently adulterated, and it then does not exhibit its ordinary odor, fusibility and volatility.

Ambergris was long regarded as a cordial and antispasmodic, somewhat analogous to musk; useful in *typhoid fevers*, and various nervous diseases. It formerly entered into many official preparations, and is still retained in some European pharmacopœias. The French Codex directs a tincture to be prepared by macerating, for ten days, 100 parts of powdered ambergris with 1000 parts of alcohol at sp. gr. 0.864, expressing and filtering. Stan. Martin assures us that the tincture will keep better, deposit nothing, and have a more agreeable odor, if the ambergris, instead of being merely powdered in a mortar, be subjected to porphyzation, especially with the addition of washed sand. Heat, he says, should never be used in its preparation. (*J. P. C.*, 4e sér., i. 448.) It is, however, feeble as a remedy, and is chiefly used in perfumery. Dose, five grains to a drachm (0.32–3.9 Gm.).

Ambrosia. *Ambrosia trifida*, L. *Ragweed*. *Ambrosia*, Fr. *Traubenkraut*, G. (Fam. Compositæ.)—This and another indigenous annual, *A. artemisiæfolia*, L., are deemed by the eclectics astringent and stimulant, and are given in low forms of fever. L. W. Schwab has found in *A. artemisiæfolia* a bitter glucoside (*A. J. P.*, 1890), and Schimmel & Co. have obtained from it about 0.15 per cent. of a green volatile oil (sp. gr. 0.876). (*Schim. Rep.*, 1904, p. 96.)

Amidoacetal. $\text{H}_2\text{N} \cdot \text{CH}_2\text{CH}(\text{O} \cdot \text{C}_2\text{H}_5)_2$.—According to the experiments of A. Malleuvre (*A. Phys.*, xlix.), this substance is an active poison, causing death in mammals by respiratory paralysis.

Amidophenols. (Derivatives of *p*-amidophenol, $\text{C}_6\text{H}_4(\text{OH})(\text{NH}_2)$.)—In an elaborate series of experiments (*Ob. I. M.*, 1897) Treupel and Hinsberg find that derivatives from amidophenol are active as antipyretics in proportion as they are decomposed in the system, and that the decomposition is to be measured by the amount of indophenol in the urine. The most important of these substances is *dulcin*, called also *para*-phenetolcarbamide and *sucrol*, $\text{CO} \begin{cases} \text{NH} \cdot \text{C}_6\text{H}_4 \cdot \text{OC}_2\text{H}_5 \\ \text{NH}_2 \end{cases}$, which

occurs in colorless crystals, melting at from 173°–174° C. (343.4°–345.2° F.), soluble in 800 parts of cold and 55 of boiling water, and 25 of alcohol, having a taste which is said to be two hundred times sweeter than sugar. It has been recommended as a substitute for sugar in *diabetes*, and, on account of its slight solubility, to improve the flavor of castor, cod liver, or other oils. According to Treupel and Hinsberg, fifteen grains (1 Gm.) of it will reduce the temperature in fever about one degree centigrade in the course of about three hours, and no unaltered dulcin is to be found in the urine, but indophenol.

Besides dulcin, Treupel and Hinsberg examined physiologically the following amidophenol derivatives: *Laetylamidophenoethylcarbonate*, *benzoyl-acetamidophenol*, *ethylacetamidophenol*, *oxyphenacetinsalicylate*.

Aminol.—This is an antiseptic liquid, colorless, slightly turbid, and having the odor of trimethylamine. It is alkaline in reaction. Sp. gr. 1.01. It is obtained commercially from herring pickle. A tablespoonful (15 Cc.) diluted with a fluidounce of water may be used for a lotion, gargle, or spray.

Ammi. *Ammi Visnaga*, Lam.—The fruit of this umbelliferous plant, indigenous in the countries around the Mediterranean, contains a crystalline principle, *kellin* (*C. R. A. S.*, August, 1879), which is said (*Union Méd.*, April, 1886) to act

upon the heart and spinal cord. Mild antipyretic and antilithic properties have been attributed to the fruit.

Ammonium Arsenate. *Ammonii Arsenas.* $(\text{NH}_4)_2\text{HAsO}_4$.—This salt is obtained in crystals by saturating a concentrated solution of arsenic acid with ammonia or ammonium carbonate, and allowing it to evaporate spontaneously. The crystals, which belong to the trimetric system, effloresce on exposure to the air, and lose half their ammonia. Its solution is alkaline. It has been used with advantage by Biett in several inveterate diseases of the skin. It is administered in solution, one grain of the salt in a fluidounce of distilled water. *Dose*, twenty to twenty-five minims (1.0–1.25 Cc.) given in divided portions in the course of the day, and gradually increased.

Ammonium Bicarbonate. *Acid Carbonate of Ammonium.* $\text{H}(\text{NH}_4)\text{CO}_3$.—This salt was brought into notice by Wm. Procter, with reference to its antacid properties. It is formed by exposure of the ordinary carbonate to the air, and is found in considerable quantities on the sides of casks in which that salt is imported, and less largely even in the bottles in which it is kept in commerce. Crystals of this salt are sometimes found in Patagonian guano and in the purifiers of gas works. When pure, the ammonium bicarbonate is white, having the same crystalline form as potassium bicarbonate, of a saline, slightly ammoniacal taste, and a feeble odor of ammonia, ascribable to a very slow volatilization. On exposure to heat, it gives off carbon dioxide. It is soluble in eight parts of water at 15.6° C. (60° F.), is nearly insoluble in official alcohol, but soluble in diluted alcohol, and its solution has an alkaline reaction with syrup of violets. It may be prepared by treating commercial ammonium carbonate (ammonium sesquicarbonate) with official alcohol, whereby the neutral carbonate is dissolved and the bicarbonate left. To render this still purer it should be washed with alcohol and dried. It is obtained as a crystalline precipitate by adding alcohol to a saturated solution of the ordinary carbonate, or by passing carbon dioxide through the same solution. It may be used as an antacid in the same manner and the same doses as sodium bicarbonate, being preferable to that salt when a stimulant impression on the stomach is desired. (*A. J. P.*, July, 1869, 294.)

Ammonium Borate. *Ammonium Metaborate.* $2\text{NH}_4\text{BO}_2 \cdot \text{H}_2\text{BO}_3 + 3\text{H}_2\text{O}$.—Only acid salts are known. By dissolving one part of boric acid in excess, in three parts of heated water of ammonia, sp. gr. 0.960, and allowing the solution to cool slowly, this salt is obtained in crystals. These are rhombic octahedrons, with truncated summits, and often truncated edges, and are semi-transparent. The taste of the salt is alkaline, and it has an alkaline reaction. On exposure, it effloresces, losing ammonia, and becoming in time the tetraborate. It is soluble in about twelve parts of water. (Gmelin, ii. 435.) Becker has used it with asserted great advantage in stone in the bladder and renal colic. Under its influence the urine becomes loaded with uric acid and the earthy phosphates. It is said also to be an excellent remedy in chronic catarrh of the bladder. It is believed by Becker to be the *ludus* of Paracelsus, which had a great reputation in the treatment of urinary calculi. *Dose*, ten to twenty grains (0.65–1.3 Gm.) every hour, in water sweetened with licorice. (*Journ. de Thérap. Méd.-Chir.*, Sept. 1, 1866.)

Ammonium Caseinate. *Ammonii Caseinas.* *Eucasinum.* *Casein-ammonium.*—A compound made by passing ammonia over casein until it is soluble in water, forming a nearly clear solution. In the form of a white or slightly yellow powder, almost without odor or taste. It is recommended as a dietetic, given in soups, chocolate, etc.

Ammonium Embelate. *Ammonium Embelicum.*—A compound of ammonia with embelic acid, an organic acid ($\text{C}_{18}\text{H}_{28}\text{O}_4$) derived from the fruit of *Embelia Ribes*, Burm. According to the experiments of G. Coronedi (*Sperimentale*, 1892, fasc. 2), this substance is a practical anthelmintic for tape worm. *Dose*, three grains (0.2 Gm.) in pill, three times a day for a child, seven times for an adult.

Ammonium Nitrate. *Ammonii Nitras.* *U. S.* 1890. *Nitrate of Ammonia.* NH_4NO_3 .—Ammonium nitrate may be prepared by treating commercial ammonium carbonate by nitric acid so long as effervescence takes place, or to saturation, filtering, and evaporating the solution. By careful evaporation and slow refrigeration the salt may be obtained in well-defined crystals. If crystallized after rapid concentration by boiling and sudden cooling, it forms long, flexible and elastic threads. If the solution be heated till all the water has been driven off and the fused mass kept at a temperature not exceeding 160° C. (320° F.), the commercial salt is produced.

“Colorless crystals, generally in the form of long, thin, rhombic prisms, or in fused masses, without odor, having a sharp, bitter taste, and somewhat deliquescent. Soluble, at 15° C. (59° F.), in 0.5 part of water, and in 20 parts of alcohol; very soluble in boiling water, and in 3 parts of boiling alcohol. When gradually heated, it melts at 165°–166° C. (329°–330.8° F.); at a temperature between 230° and 250° C. (446°–482° F.) it is decomposed into nitrogen monoxide gas and water, leaving no residue. The aqueous solution of the salt is neutral to litmus paper, and when gently heated with potassium or sodium hydrate test-solution, it evolves the odor of ammonia. On heating the salt with sulphuric acid, it emits nitrous vapors.” *U. S.* 1890.

At all temperatures between –15° C. (5° F.) and 25° C. (77° F.), if exposed to a current of dry ammoniacal gas, its crystals absorb the gas and melt, yielding a colorless liquid, which, if the absorption has taken place at –10° C. (14° F.), contains two molecules of the gas for each molecule of the salt, and would be represented by the formula $\text{NH}_4\text{NO}_3 + 2\text{NH}_3$. It is not frozen by a mixture of salt and snow. Its sp. gr. is 1.05. Heated moderately it boils, with loss of ammonia, and is changed into a crystalline mass, containing 22.41 parts of the gas in 100 of the salt by weight, corresponding with the formula $\text{NH}_4\text{NO}_3 + \text{NH}_3$, thus retaining one-half the gas absorbed. By exposure to increased heat, this loses ammonia, and at 80° C. (176° F.) has been reconverted to pure ammonium nitrate. This preparation may be used for obtaining small quantities of pure ammonia, when wanted, by exposing it to a gentle heat in a small retort. To be fit for this purpose, it must be kept at a low temperature. (*P. J.*, June, 1872.) “A 10-per-cent. aqueous solution of the salt, when acidulated with nitric acid, should not be affected by silver nitrate test-solution (absence of chloride), nor by barium chloride test-solution (absence of sulphate).” *U. S.* 1890.

For the mode of preparing nitrogen monoxide (hyponitrous oxide), or nitrous oxide gas, from ammonium nitrate, see *Nitrogen Monoxide*.

Ammonium Persulphate, $(\text{NH}_4)_2\text{S}_2\text{O}_8$, is prepared by electrolyzing an acid solution of ammonium sulphate, and is a most efficient oxidizing agent in acid, neutral, or alkaline solutions. It occurs in small, colorless crystals, soluble in water. Its solution evolves oxygen when heated, and is used as an antiseptic for preserving meat and other food, and as a cheap and effective mouth wash. Ammonium persulphate is much used in photography as a reducing agent. In medicine it is chiefly valuable as forming the basis of *Klett's test* (*Chem. Ztg.*, 1900, p. 690) for indican in urine. To 10 Cc. (160 minims) of urine add 5 Cc. (80 minims) of 25 per cent. hydrochloric acid together with a crystal of ammonium persulphate, to which add chloroform, when a blue color develops in the latter.

Ammonium Sulphate. *Ammonii Sulphas*. U. S. 1880. *Sulphate of Ammonium*. $(\text{NH}_4)_2\text{SO}_4$; 131.21. *Ammonium Sulphuricum*. *Sal Ammonium Secretum Glauberi*. *Sulfate d'Ammoniaque*, *Sel secret de Glauber*, Fr. *Schwefelsaures Ammon*, *Ammonium*, *Ammoniak*, G.—Gas liquor is distilled with lime and the gas received in sulphuric acid, which yields a purified product. Most of the ammoniacal liquor is worked up into ammonium sulphate at present. The English production from gas works, shale distilling, and coke ovens amounted in 1902 to 221,500 tons, that of Germany to 100,000, and France 35,000 tons. In the United States the production from gas works amounted in 1890 to 11,000 tons, and has probably not increased because of the general introduction of water gas processes, in which no ammoniacal liquor is formed; on the other hand, the production in connection with the coking of coal has increased very rapidly. The total production of ammonia from gas works and coke ovens, as reported for 1904, was, when reduced to terms of ammonium sulphate, 52,463 tons (*Mineral Resources of the U. S.*, 1904). "Colorless, transparent, rhombic prisms, permanent in the air, odorless, having a sharp, saline taste and a neutral reaction. Soluble in 1.3 parts of water at 15° C. (59° F.) and in 1 part of boiling water; insoluble in absolute alcohol, but slightly soluble in alcohol of sp. gr. 0.817; when heated to about 140° C. (284° F.), the salt fuses, is gradually decomposed, and on ignition is wholly dissipated. The aqueous solution of the salt, when heated with potassa, evolves vapor of ammonia. With test-solution of chloride of barium it yields a white precipitate insoluble in hydrochloric acid. A 1 per cent. solution of the salt should not be blackened by test-solution of sulphide of ammonium (lead and iron), nor, when acidulated with nitric acid, should it be rendered more than opalescent by test-solution of nitrate of silver (limit of chloride)." U. S. 1880. It is not used as a medicine, but enters into the composition of ammonium alum and the iron and ammonium sulphate.

Ammonium Urate. *Ammonii Uras*. $\text{C}_5\text{H}_8(\text{NH}_4)\text{N}_4\text{O}_8$ —This is an acid salt, and may be formed by digesting uric acid in solution of ammonia, or by adding sal ammoniac to the solution of other urates. Uric acid is frequently obtained from the dried and powdered excrements of the boa serpent, and of other large snakes, by dissolving it in a weak solution of potassium hydroxide with the aid of heat, and precipitating the uric acid from the filtered solution by hydrochloric acid, added in excess. Ammonium urate is a white, amorphous, very sparingly soluble salt. It is a con-

stituent of some varieties of guano. It has been used with asserted good effects externally in chronic eczema, in the form of an ointment (twenty grains to the ounce). (See 16th edition U. S. D.) Neubauer found that when given internally to rabbits it causes increase in the urea, uric acid, and oxalates of the urine. (*Ranking's Abstract*, 1857.)

Ammonol.—This proprietary remedy is stated by its manufacturers to be *ammoniated-phenyl-acetamide*. It has been used internally as an analgesic in doses of from five to ten grains (0.3–0.65 Gm.). According to the analysis of George M. Beringer (*A. J. P.*, lxxix. p. 150), it is composed of acetanilide, 10 Gm.; sodium bicarbonate, 5 Gm.; ammonium bicarbonate, 5 Gm.; metanil-yellow, 0.005 Gm.

Amygdophenin. *Phenyl-glycolyl-phenetidine*. This is a derivative of *p*-amidophenol, analogous to phenacetin. In constitution it is a light, crystalline, grayish-white powder, soluble with difficulty in water. It is obtained by the action of mandelic acid upon *p*-phenetidin in the presence of dehydrating agents. R. Stüve asserts that it is practically free from antipyretic properties; that it is an analgesic which is often useful in *neuralgias* and the pains of *spinal sclerosis*; and that it is very useful in *rheumatism*, it having had more effect in some comparative trials than the salicylates. It is best administered in capsules, fifteen grains (1 Gm.), from three to six times a day.

Amyl Alcohol. *Alcohol Amylicum*. *Amylio Alcohol*, $\text{C}_5\text{H}_{11}\text{OH}$. *Fusel Oil*. *Hydrated Oxide of Amyl*. *Fousel Oil*. *Hydrate of Amyl*. *Grain Oil*. *Potato Spirit Oil*. *Alcool Amylique*, *Huile de Grain*, Fr. *Amylalcool*, *Fuselöl*, G.—This oil is always present in the products of alcoholic fermentation, and, according to the experiments of L. Perdrix (*J. Chem. S.*, 1892, 90), the bacillus *B. amylozymicus* produces a fermentation in starch resulting in the large production of amyl alcohol. It is an ingredient in the ardent spirit obtained from various grains, but is most abundant in that procured from fermented potatoes. In grain spirit it is present in the proportion of about one part in five hundred by measure. When grain or potato whisky is distilled for the purpose of obtaining alcohol, the pure spirit will continue to come over for a certain time, after which, if the distillation be continued, a milky liquid will be obtained, which, upon standing, will be covered with a stratum of this peculiar oil. Subjected to distillation, the milky liquid will at first boil at a comparatively low temperature, and yield water and a little of the oil; but after a time the boiling point will rise to 132° C. (269.6° F.), when the oil will come over pure, and by changing the receiver may be so collected.

Properties.—Amyl alcohol is an oily, colorless liquid, of a strong, offensive odor, and an acid, burning taste. As usually prepared it has a pale yellow color. Its sp. gr. is 0.818; that of its vapor 3.15. It boils at 132° C. (269.6° F.), and congeals at –25° C. (–13° F.) in the form of crystalline leaves. It is very sparingly soluble in water, but unites in all proportions with alcohol, ether, and essential oils. It dissolves iodine, sulphur, and phosphorus, and is a good solvent for fats, resins, camphor, and alkaloids. When dropped upon paper it does not leave a permanent greasy stain. It does not take fire like alcohol by the contact of flame, but requires to be heated to a temperature of about 54.5° C. (130° F.) before it begins to burn. Pasteur first observed that the

ordinary amyl alcohol of fermentation was a mixture of two distinct alcohols, one present in smaller amount, optically active, lævogyrate, and the other, the main portion, optically inactive. Their boiling points are very close, but they may be separated by the difference in solubility of the barium amyl-sulphates, and yield different sets of derivatives. (*C. R. A. S.*, 41, 296.) Amyl alcohol consists of five atoms of carbon 59.55, twelve of hydrogen 12, and one of oxygen 15.8 = 87.43. It is recognized as the hydroxide of the radical amyl (C_5H_{11}), and its formula is, therefore, $C_5H_{11}.OH$. Heated with phosphoric oxide, it loses a molecule of water, and forms a hydrocarbon, C_5H_{10} , homologous with ethylene, called *amylene* or *valerene*, which has been proposed as an anæsthetic. According to Long and Linebarger, American fusel oil consists chiefly of active and inactive amyl alcohol, with some isobutyl alcohol, isopropyl and ethyl alcohols, and traces of normal propyl and normal butyl alcohols. (*Chem. News*, lxi. 185-187.) Amyl alcohol should not affect the color of litmus paper, previously moistened with water, should leave no fixed residue upon evaporation, should require to dissolve it about 40 parts of distilled water at 15° C. (59° F.), and should become not more than slightly turbid upon mixture with petroleum benzin (absence of more than a little alcohol, or water). (See *Amylene* below.) When subjected to oxidizing agents, it loses two atoms of hydrogen and gains one of oxygen, and becomes $C_5H_{10}O_2$, or *valeric acid*, the acid found in valerian. Hence the test given in the Br. Pharmacopœia of 1885: "exposed to the air in contact with platinum-black, it is slowly oxidized, yielding valerianic acid." This acid bears the same relation to amyl alcohol that acetic acid does to ethyl alcohol, and formic acid to methyl alcohol. The free amyl, $(C_5H_{11})_2$, has been isolated by E. Frankland. It is a colorless pellucid liquid, of the sp. gr. 0.7704. (*Chem. Gaz.*, March 15, 1850.) Its hydride, $C_5H_{11}H$, was discovered to be an energetic anæsthetic by Simpson of Edinburgh.

Crude fusel oil may be obtained from the alcohol distillers. Kent of New York, found in it, as impurities, water, alcohol, acetic and valeric acids, oxide of iron, and an amyl compound analogous to *cananthic ether*. Fusel oil has been used largely by the manufacturers of alkaloids as a solvent and in the preparation of *amyl acetate* (*pear oil*), which is used in the manufacture of pyroxylin varnishes and smokeless powder. This manufacture of amyl acetate for solvent purposes now consumes the great bulk of the fusel oil obtained from the rectifiers.

Fusel oil was formerly recognized by both the United States and the British Pharmacopœias as an artificial source of valeric acid.

Amyl alcohol is a very active narcotic, and under the name of *Faints* is used in England and Northern Europe for the purpose of increasing the activity and prolonging the effects of ordinary liquors. In small doses it is said to be especially efficacious in controlling the nervous weakness and irritability of confirmed drunkards, while larger doses produce headache, giddiness, double vision, staggering, unconsciousness, fall of temperature, abolition of reflexes, muscular rigidity, followed by complete relaxation, pronounced cyanosis, and a peculiar odor from the breath suggesting that of a Jargonelle pear.

T. B. Fletcher (*Am. Med.*, August, 1901, p. 210) has shown that both in animals and also in

man, when taken in toxic doses, fusel oil affects profoundly the blood, causing methæmoglobinuria, also glycosuria, attended with the presence of combined glycuronic acid, and in some cases violent nephritis. The size of the fatal dose probably varies very much. It is affirmed that death occurred from the taking of a single fluidounce (30 Cc.), but in another case recovery resulted after six fluidounces (180 Cc.) had been swallowed.

Amyl Salicylate. Salicylic Amylester.

A colorless and refracting fluid, emitting an odor resembling that of salol, having the sp. gr. 1.065 at 15° C. and made by the action of chlorine on a solution of salicylic acid in amyl alcohol. It boils at 270° C. (518° F.). The preparation dissolves in ether, alcohol, and chloroform, but it is almost insoluble in water. This substance has been proposed by B. Lyonnet (*R. T.*, lxxviii. No. 2) as a substitute in *rheumatism* for methyl salicylate, over which it has the advantage of less pronounced odor and taste. It is given internally usually in gelatin capsules, three to five minims (0.2-0.3 Cc.) each, eight or ten times a day. It has also been found very useful as a local application, one-half to one drachm (2.0-3.9 Gm.), being applied to rheumatic joints and covered with wax paper, or other impervious dressing.

Amyl Valerate.—This liquid is said by W. F. Wade of Birmingham, to act similarly to valerian, and to afford a most valuable remedy. He dissolves one part of it in nineteen parts of alcohol and 2 per cent. of a spirit of amyl acetate (one part to twenty). The dose of this mixture is from six to eight minims (0.4-0.5 Cc.).

Amylamine Hydrochloride, Amylamine Chloride, $C_5H_{13}N.HCl$, crystallizes either in efflorescent scales or in quadrate octahedrons. According to Dujardin-Beaumetz (*C. R. A. S.*, lxxvii. 1247), in small doses (from $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.001-0.005 Gm.) to a rabbit) this salt lowers the temperature and also the force and frequency of the pulse. In larger amounts it produces profound nervous disturbance, with tonic and clonic convulsions, ending often in death. In man, doses of from seven to fifteen grains (0.45-1.0 Gm.) diminish the pulse and temperature.

From amylamine hydrochloride by boiling with an excess of calcium chloride is formed *amyldichloramine*, a yellowish-green oily liquid, the smelling of which produces violent irritation of the nose, followed by severe headache and vertigo. According to the researches of Boinet (*Congrès Français de Méd.*, 1, 1894), it is not only a violent local irritant, but also a powerful centric poison, producing death by asphyxia. Boinet has also examined physiologically *propyldichloramine* and *isobutyldichloramine*, finding that they are similar in their toxic influence to amyldichloramine.

Amylene. Valerene. Pentene. C_5H_{10} .—This compound was alluded to under amyl alcohol. The name is given to the isomeric hydrocarbons of the *olefin* series, having the formula C_5H_{10} , of which five are possible. Amylene is prepared by distilling amyl alcohol with a concentrated solution of zinc chloride, which acts by dehydrating, withdrawing a molecule of water. The product is redistilled, and that which comes over first, constituting the more volatile part, is separately collected, and agitated with concentrated sulphuric acid, when the amylene, freed from water, will

rise to the surface. Amylene is a colorless, very mobile liquid, having the density 0.655 at 10° C. (50° F.). Its boiling point is 34° C. (93.2° F.). Its odor is peculiar and disagreeable. It is soluble in alcohol and ether in all proportions, but very sparingly so in water. When pure it does not act on potassium, and is not colored by a prolonged contact with potassium hydroxide.

In 1857, Snow of London, proposed amylenes as an anæsthetic. It was soon shown, however, to be dangerous, the French Academy of Medicine formally condemning it.

Amylene Hydroxide. Tertiary Amyl Alcohol. Dimethylethylcarbinol ($C_5H_{12}O$ or $(CH_3)_2C_2H_5COH$) is a clear, colorless liquid, of a strong, penetrating odor, soluble in eight parts of water, and miscible with alcohol, ether, chloroform, petroleum benzine, glycerin, and fixed oils in almost all proportions; sp. gr. 0.812 at 12° C. (53.6° F.).

In 1887, von Mering proposed the use of amylenes hydroxide as a soporific, stating that it stood midway between hydrated chloral and paraldehyde, one drachm (3.9 Gm.) of hydrated chloral, two drachms (7.7 Gm.) of amylenes hydroxide, and three drachms (11.6 Gm.) of paraldehyde being about equivalent in power. In cases of poisoning, reported by C. Dietz, by the amylenes hydroxide, the symptoms were deep narcosis, dilated pupils, loss of corneal reflexes, slow, deep, irregular breathing, small, slow pulse, and fall of temperature. Amylenes hydroxide is a safe, rapidly acting, and occasionally useful but not analgesic hypnotic, in doses of from thirty to forty minims (1.8–2.5 Cc.). According to Brackmann, confirmed by W. Niessen, it is very valuable in *diabetes insipidus*, lessening thirst and polyuria. *Dose*, fifteen minims (0.9 Cc.) morning and evening.

Pental. Trimethylethylene. β -isomylene, $(CH_3)_2C=CH.CH_3$, or C_5H_{10} , is obtained from crude amylenes, which consists of pentane (C_5H_{12}), pental (C_5H_{10}), and α - and γ -amylenes. If the mixture be shaken with diluted sulphuric acid at a low temperature, $-20^\circ C.$ ($-4^\circ F.$), the trimethylethylene and γ -amylenes will be decomposed and amylsulphuric acid produced, which after dilution with water yields tertiary amyl alcohol and trimethylethylene; by fractional distillation the pental is obtained in a pure state.

Pental is a colorless, highly inflammable liquid; sp. gr. 0.678; boiling point 38° C. (100° F.). It was highly commended by W. Lombardino as an anæsthetic of great practical value. H. C. Wood and David Cerna have, however, shown that pental acts upon the lower animals as a powerful cardiac depressant, and is probably a dangerous anæsthetic. The more recent clinical trials of the drug have proved that this danger is real, there having been, according to the statistics of Gurlt, in six hundred pental narcoses, six deaths. Moreover, N. Kleindienst found that very frequently in man severe albuminuria, and not infrequently hæmaturia and hæmoglobinuria, occurred three or four days after pental narcosis.

Pentane.—Amyl hydride, $CH_3CH_2CH_2CH_2CH_3$, was discovered by E. Frankland of Manchester. It is a saturated hydrocarbon, and has been proved to be one of the light products in American petroleum, being the portion boiling at from 37°–39° C. (99°–102° F.) (Schorlemmer). Amyl hydride is a colorless, volatile, mobile liquid, possessing a grateful fruity odor, having no taste. It is one of the lightest liquids known, having the sp. gr. 0.626 at 17° C. (63° F.). It boils at 38°

C. (100° F.), and the sp. gr. of its vapor is 2.5. It is very inflammable, and burns with a brilliant white flame. It is readily soluble in alcohol and ether, but insoluble in water. Belonging to the paraffin or saturated series of hydrocarbons, it is a very stable compound, resisting the action of fuming sulphuric acid and the most powerful oxidizing agents. This substance was proposed by Simpson as an anæsthetic, but has not sustained the claims made for it.

Amylene Chloral. Dormiol.

This is an alcoholate formed by the union of chloral and amylenes hydroxide. It is a colorless, oily fluid of sp. gr. 1.24, having a peculiar camphor-like odor and a cooling, pungent taste. It is insoluble in water but is miscible in all proportions with alcohol, ether, acetone, and fixed oils. There is a large amount of clinical evidence as to the value of dormiol in all forms of insomnia which are not dependent upon the existence of pain. It is employed largely in insane asylums and the testimony is uniform that it acts favorably in about 70 per cent. of the cases, that it produces no disagreeable after-effects, and that when continuously exhibited it produces no chronic poisoning. It is further claimed that it may be used in cardiac cases when hydrated chloral would be dangerous. It acts promptly and produces a quiet sleep, which is often of very short duration; further, patients become rapidly accustomed to its use. *Dose*, ten minims to a fluidrachm (0.6–3.75 Cc.). It may be given in capsules or emulsion, but it is well taken when dropped in cold water and rapidly swallowed.

Amyloform is a patented chemical compound of formaldehyde and starch, introduced by Claassen as a substitute for iodoform. It is stated to be odorless, innocuous, and non-irritant. *Dextroform* is a similar compound, in which dextrin is used in place of starch. Dextroform is soluble in water and glycerin. Amyloform can be heated to 180° C. without decomposition, and therefore is readily sterilized. It is said to be non-poisonous, and has been used by Langgard, Krabbel, and others as a dusting powder in the treatment of infected ulcers and wounds of all kinds. It is said to act more energetically in lessening secretion and as a disinfectant than iodoform.

Amytin.—Under the name of amylin, Unna has introduced into medicine a 33 per cent. aqueous solution of *ichthyol-sulphonic acid*, which has the property of dissolving ichthyol, various ethereal oils, phenol, and camphor, forming solutions which are known by Unna as *Amytoles*. Many of these amytoles, especially those made with a phenol, are powerfully antiseptic. The 10 per cent. cresol solution is said to entirely disinfect catgut ligatures in from thirty-six to forty-eight hours, after which time the ligatures must be removed and preserved in alcohol. Amytin is more or less irritant to the skin, and is affirmed to be useful in those skin diseases which need stimulation. It is stated that a 3 per cent. solution of the cresol amytole affords an excellent means of disinfecting the hands, and is very actively poisonous against the diphtheritic bacillus.

Anacahuite Wood.—In the year 1860 considerable quantities of this wood were imported from Mexico, into Germany, as a supposed remedy in *phthisis*, but it failed to sustain its first reputation. It is the product of *Cordia Boissieri*, De Cand. (See *P. J.*, Dec. 1862, 272, with figure.)

Anacardium. *Anacardium occidentale*, L. *Cas-sivium pomiferum*, Lam. *Cashew-nut*. *Acajou à Pommes*, Fr. *Caschunuss*, G.—A small and elegant tree of the Fam. Anacardiaceæ, growing in the West Indies and other parts of tropical America. A gum exudes from the bark, which bears some resemblance to gum arabic, but is only in part soluble in water, and consists of true gum and bassorin. It is the *gomme d'acajou* of the French writers. Peckoldt describes *cashew gum* as occurring in hard, fragile pieces which are more or less transparent, yellowish-brown, uviolar and stalactite-shaped; it is as soluble in water as acacia. (*Zeit. Oest. Apoth. Ver.*, 1893, 501.) The fruit is a fleshy, pear-shaped receptacle, supporting at its summit a hard, shining, ash-colored, kidney-shaped nut, an inch or more in length and three-quarters of an inch broad, consisting of two shells, with a black juice between them, and of a sweet oily kernel. The receptacle is red or yellow, and of an agreeable subacid flavor with some astringency. It is edible, and affords a juice which has been recommended in *uterine complaints and dropsy*. This juice is converted by fermentation into a vinous liquor, which yields by distillation a spirit used in making punch, and said to be powerfully diuretic. The nuts are well known under the name of *cashew-nuts*. The black juice contained between their outer and inner shell is extremely acrid and corrosive, producing, when applied to the skin, severe inflammation, followed by blisters or desquamation. Staedeler found in it two peculiar principles,—*anacardic acid* and a yellow, oleaginous liquid, *cardol*. (See *J. P. O.*, 3e sér., xiii. 459.) The juice is used in the West Indies for the cure of *corns, warts, ringworms*, and obstinate *ulcers*, and even of *elephantiasis*. It is said to be sometimes applied to the face by women, in order to remove the cuticle, and produce a fresher and more youthful aspect. In a case of external poisoning which came under our notice, in a lady who was exposed to the fumes of the roasting nuts, the face was so much swollen that for some time not a feature was discernible. (*N. J. Med. Rep.*, 1855, 187.) In the case of a boy the tongue, face, neck, hands, forearms, scrotum, etc., were red and enormously swollen, and very painful. The tincture of iodine was found useful as a local application. The kernel has a sweet, agreeable taste, and is eaten like chestnuts, either raw or roasted, in puddings, and as a chocolate when ground with cocoa. By age it becomes rancid. The black juice of the nut and a milky juice which flows from the tree after incision are used for almost indelibly marking linen.

Anæsthesin. The ethyl-ester of *p-amido-benzoic acid*, $C_6H_4 \begin{matrix} \text{NH}_2 \\ \text{COOC}_2\text{H}_5 \end{matrix}$. This name is given by E. Ritsert to the ethyl-ester of *p-amido-benzoic acid*. It is a white, inodorous, crystalline powder, melting at 89.5° C. (193° F.), sparingly soluble in cold water, readily soluble in acetone, ether, petroleum benzin, chloroform, and in ethereal and fatty oils. The solutions do not alter even when exposed to light.

Anæsthesin hydrochloride is soluble in 100 parts of water. This solution when injected, however, causes some unpleasant burning sensation and may be diluted to one-fourth. It is claimed for anæsthesin that while not poisonous it is an active local anæsthetic and may be freely injected in solution for surgical purposes. In the experiments of Binz colossal doses given to rabbits were found to produce only a transient methæmoglo-

binæmia. No renal irritation or methæmoglobinuria were ever observed. Dunbar commends the following formula: Anæsthesin hydrochloride, 0.25; sodium chloride, 0.15; morphine hydrochloride, 0.005 to 0.015; water, 100; the solution can be sterilized. Anæsthesin is strongly commended internally, for the relief of *gastro pain and vomiting*. Lozenges containing from three-tenths to six-tenths of a grain (0.019–0.038 Gm.) are stated to be effective in relieving irritation of the throat and palate. Anæsthesin has been found very useful, in the form of suppositories containing from three to eight grains (0.2–0.5 Gm.), for the relief of painful *hemorrhoids*; it is also used in soluble bougies (five grains or 0.3 Gm.) in the vesical *tenesmus* of women; in the form of an ointment (10 per cent.) in *pruritus vulvæ* of *diabetes* and other conditions, also in various *eczemas* about the genitalia. *Dose*, five to seven grains (0.3–0.45 Gm.).

Anagallis. *Anagallis arvensis*, L. *Scarlet Pimpernel*. *Red Chickweed*. *Weather-glass*. *Mouron rouge*, Fr. *Gauchheil*, *Rothe Miere*, G. (Fam. Primulacæ).—An annual plant, growing in Europe and the United States. It has little odor, but a bitterish, somewhat acrid taste. The ancients esteemed it a counter-poison, and Orfila found three drachms of its extract to cause fatal gastroenteritis in a dog. It has been recommended as a local application to old and ill-conditioned *ulcers*, and has been given internally in *visceral obstructions, consumption, dropsy*, etc. J. A. Heintzelman obtained from it a volatile oil of a strong peculiar odor, a pungent and somewhat acrid taste, and the sp. gr. 0.987. Four drops (0.2 Cc.) of it produced intense headache and nausea, lasting for twenty-four hours, with pains throughout the body. According to Dacomo and Tommasoli, anagallis contains an active ferment, which rapidly digests raw meat. (*Rassegna di Sci. Med.*, 1892, No. 4.) *A. cœrulea*, Lam., is probably a variety of *A. arvensis*, and shares its medicinal properties.

Anagyris. *Anagyris fetida*, L. (Fam. Leguminosæ).—Hardy and Gallois have separated from *Anagyris fetida* an alkaloid, *anagyrine*. This alkaloid, according to Loewi (*A. L. P.*, vol. vii. p. 66), is physiologically related to lobeline, acting primarily upon the nerve endings as a paralyzant and later upon nerve centres, but having no direct influence upon the muscles. It lessens the cardiac frequency and decreases the force of the systole in the frog, but is said in the mammal to have very little influence upon the blood pressure, death occurring through respiratory paralysis.

Analgen. *Ortho-ethoxy-anamonobenzoylamidoquinoline*. *Benzanalgene*. *Quinalgene*. *Labordin*. $C_{15}H_{16}N_2O_2$.—The name analgen was first given to the acetyl derivative, but it was found that the benzoyl radical gave a more desirable product, and this is now made exclusively and the name analgen applied to it. It is in colorless crystals, insoluble in water, soluble in hot alcohol, melting point 203° C. (406° F.).

First produced and brought forward by Vis as an antipyretic, analgesic, and antirheumatic remedy, it was subsequently investigated by Maass (*Z. K. M.*, xxviii. 1895), who found that in sufficient dose it depresses the heart and the reflexes, finally causing convulsions with loss of power, and death by centric paralysis of respiration. Both it and its derivative, *oxyethylamidoquinoline*, act upon the peripheral nerves as local anæsthetics. The fatal dose for the lower animals was found

by Maass to be three grammes per kilo. The continuous use of small doses produces emaciation, feebleness, and lessening of the reflexes. In cases of fever it causes active depression of temperature, often with free sweating, and usually decrease in the urinary secretion, and especially of the nitrogenous elimination. After chronic poisoning in the lower animals fatty degeneration was found in the liver and kidneys. The urine of patients taking it is said to become red, owing to the presence of *oxyethylamidoquinoline urate*. In headaches and the other nervous disturbances of chlorotic neurasthenic individuals it is said to act well without affecting digestion. It is said also to relieve the pain of organic diseases, and to be distinctly anti-malarial. (See *B. A. M.*, xxxvi.) *Dose*, eight to fifteen grains (0.5–1.0 Gm.), increased to seventy-five grains (5 Gm.) a day if required; best administered in capsule or in acidulated water.

Anchietea. *Anchietea salutaris*, St. Hil. *Cipo Suma*. *Cipo Carneiro*. *Pirageia*.—The bark of the root of this Brazilian plant contains *anchietine*, an alkaloid isolated by Peckoldt. (*Ber. d. Chem. Ges.*, 1897, No. 3, p. 98.) It is used in Brazil in treating *scrofula*, *erysipelas*, and *eczema*. Given in doses of two drachms (7.7 Gm.), it acts as an aperient, while three drachm (11.6 Gm.) doses produce vomiting.

Anchusa. *Anchusa officinalis*, L. Bugloss. *Ox-tongue*. (Fam. Boraginaceæ.)—The root, leaves, and flowers of this European biennial plant were at one time recognized by the U. S. Pharmacopeia, but probably are practically devoid of medicinal properties. In France the *Anchusa italica*, which is there known as *buglosse*, is substituted for *A. officinalis*.

Andrographis. *Br. Add.* *Andrographis paniculata*, Nees. (Nat. Ord. Acanthaceæ.)—Under the name of *Kiryat* this plant is stated to be used to some extent in India as a bitter tonic, having similar properties to *chiretta*. It appears scarcely to enter commerce at all, although exposed in the shops of the herbalists. The *Br. Add.* recognizes the *infusion* (*Infusum Andrographidis*, *Br. Add.*, one ounce to a pint), *dose*, one-half to one fluidounce (15–30 Cc.); the *concentrated liquor* (*Liquor Andrographidis Concentratus*, *Br. Add.*), *dose*, one-half to one fluidrachm (1.8–3.75 Cc.); and the *tincture* (*Tinctura Andrographidis*, *Br. Add.*), *dose*, one-half to one fluidrachm (1.8–3.75 Cc.).

Andromeda. *Oxydendrum arboreum* (L.), DC. (*Andromeda arborea*, L.), *Sour Wood*, or *Sorrel-tree*, grows in the valleys of the Alleghannies, from Pennsylvania to Florida. Barton in his *Collections* states that a decoction of *Pieris Mariana* (L.), B. and H. (*Andromeda Mariana*, L.), or *stagger-bush*, is employed in the Southern States as a wash in ulcerations of the feet. The powder of the leaves and buds of *Leucothoe racemosa* (L.), A. Gray (*Andromeda racemosa*, L.), is said to be a powerful emmenagogue. J. F. Eykman of Japan, found a poisonous glucoside, *asebotowin*, in *Andromeda* (*Pieris*) *japonica*. (*N. R.*, 1882, 290.) In 1883, Plüggé separated from *Andromeda japonica* a colorless crystallizable poisonous principle, *andrometowin*. Subsequently he found that various ericaceous plants contain it. (*A. Pharm.*, xxvi.; also *A. J. P.*, 1889.) It exists in *Azalea indica* and *Rhododendron maximum*, L., and has been found by De Zaayer (*Chem. Ztg.*, July, 1887) in *Rhododendron ponticum*, and in *Kalmia angustifolia*, L.,

and *K. latifolia*, L.; also in *Monotropia uniflora*, L., by A. J. M. Lasché (*Ph. Rund.*, Sept. 1899). It occurs in acicular crystals, melting at from 228° to 229° C. (442°–444° F.), soluble in alcohol, amyl alcohol, chloroform, ether, benzene, much more soluble in cold than in boiling water, yielding solutions of an alkaline reaction, but not precipitated by ordinary alkaloidal reagents nor by solutions of metallic salts. For further tests, see reference; also *P. J.*, vol. xviii. 171. The *poisonous honey* of Xenophon, derived from the flowers of *R. ponticum*, probably owed its toxic properties to andrometowin. (See also *Ph. Z. R.*, 1883, xxii.) The oil of *A. Leschenaultii*, of India, was found by J. Broughton to be methyl salicylate. (*P. J.*, Oct. 1871.)

Aneson. *Anesim. Anäsin*.—This is a patented 1 per cent. aqueous solution of *tri-chlor-pseudo-butyl-alcohol* or *acetone-chloroform*, $\text{HO}(\text{C}_2\text{H}_5)_2\text{CCl}_3 + \frac{1}{2}\text{H}_2\text{O}$. This compound is obtained when acetone combines with chloroform in the presence of caustic alkalis.

It was first studied pharmacologically by J. Kossa, and subsequently by Zoltán von Vámosy. (*D. M. W.*, xxiii.) It is alleged that it is a powerful local anæsthetic, equivalent to a 2½ per cent. solution of cocaine, and having the advantage of being non-irritant and non-toxic, and of not being mydriatic. Its anæsthetic effects are said to be of slow development, as it seemingly does not pass rapidly through the mucous membrane. Internally acetone-chloroform is affirmed to resemble hydrated chloral in its hypnotic action in doses of from eight to fifteen grains (0.5–1.0 Gm.).

Angelica. *Racine d'Angélique*, Fr. *Engelwurz*, G.—*Angelica atropurpurea*, L. (Fam. Umbelliferae), sometimes called *masterwort*, grows throughout the Eastern United States. The whole plant was formerly official. It has a strong odor and a warm aromatic taste. The juice of the recent root is acrid, and is said to be poisonous; but the acrimony is dissipated by drying. The medicinal virtues of the plant are similar to those of the garden angelica of Europe, for which it has been proposed as a substitute. It is however inferior to the European angelica.

Angelica Archangelica, L. (*Archangelica officinalis*, Hoffm.)—Garden angelica has a long, thick, fleshy, biennial root, furnished with many fibres, and sending up annually a hollow, jointed, round, channelled, smooth, purplish stem, which rises five feet or more in height, and divides into numerous branches. The leaves, which stand upon round fistulous footstalks, are very large, doubly pinnate, with ovate-lanceolate, pointed, acutely serrate leaflets, the terminal being three-lobed. The flowers are small, greenish white, and disposed in very large, many rayed terminal umbels, composed of numerous dense, hemispherical umbellules. This plant is a native of the north of Europe, and is found in the high mountainous regions in the southern section of that continent, as in Switzerland and among the Pyrenees. It is often cultivated. The whole plant is aromatic, but the root and the fruit only were official. The root should be dug up in the autumn of the first year, as it is then least liable to become mouldy and worm eaten. It is spindle-shaped, an inch or more thick at top, and beset with long descending radicles. The fresh root has a yellowish-gray epidermis, a fleshy yellow parenchyma, and when wounded yields a honey-colored juice, having all the aromatic properties of the plant. The dried root is grayish brown and much wrinkled ex-

ternally, whitish and spongy within, and breaks with a starchy fracture, exhibiting shining resinous points. It is very apt to be attacked by worms, and is said to keep best, in the state of powder, in full and well-closed vessels. The odor is strong and fragrant, and the taste at first sweetish, afterwards warm, aromatic, bitterish, and somewhat musky. These properties are extracted by alcohol, and less perfectly by water. The constituents of the root, according to the younger Buchner, are volatile oil, a volatile acid which he called *angelicic acid*, a wax-like substance, a crystallizable sub-resin, a brittle amorphous resin, a bitter principle, tannic acid, malic acid, sugar, starch, albumen, pectic acid, fibrin, and various salts. Five hundred parts yield nearly four parts of the volatile oil. Schimmel & Co. (*Ber. d. Chem. Ges.*, April, 1889) report the results of an examination of *Japanese angelica*, believed to be roots of *A. refracta* or *A. anomala*. It contained a small quantity of volatile oil, which had an extremely persistent odor. The *angelicic acid* of Buchner is now known as *angelic acid*, $C_6H_8O_2$, a monatomic acid of the acrylic acid series. *Valeric acid*, $C_6H_{10}O_2$, has also been recognized as occurring in the root. The volatile oil has been examined by Beilstein and Wiegand, who found three terpenes: one boiling at $158^\circ C.$ ($316^\circ F.$), forming no crystallizable hydrochloride; the second boiling at $175^\circ C.$ ($347^\circ F.$) and forming a crystalline hydrochloride having the properties of artificial camphor, and constituting the main body of the oil; and a third, boiling at $250^\circ C.$ ($482^\circ F.$). (*Ber. d. Chem. Ges.*, 1882, 1741.) The main terpene product is now recognized as *phellandrene*. Besides *valeric* (*methyl-ethylacetic*) acid, *oxymyristic*, $C_{14}H_{26}O_3$, and *oxypentadecylic acids* ($C_{15}H_{30}O_3$), have been identified. (*Schim. Rep.*, April, 1897.) The seeds, as the fruit is commonly called, are two or three lines long, oval, obtuse, or somewhat notched at the ends, flat, with a longitudinal furrow on one side, convex with three angular ridges on the other. They are ash-colored, and have the odor and taste of the root. They are said to keep well.

Garden angelica is an aromatic tonic. The Laplanders, in whose country it flourishes, esteem it highly as a condiment and medicine. In Europe the stems are frequently made into a preserve. The dose of the root or seeds is from thirty grains to a drachm (2-3.9 Gm.).

Angræcum. *Angræcum fragrans*, Thouars. This is an orchidaceous plant, indigenous to the Isle of Réunion and Mauritius, where the leaves have been long used, under the name of *faham*, for the same purposes as Chinese tea. For description, see *P. J.*, 1881, 913. They have a somewhat pungent aromatic taste, and a strong and highly agreeable odor, scenting the whole apartment with a delicious perfume. Given in infusion, they appear to have an effect on the system, somewhat similar to that of Chinese tea, and they have been introduced into Paris as a rival of that popular beverage. The drink is made by putting the leaves and stalks, in the proportion of fifteen grains (1 Gm.) to a teacupful, into cold water, boiling for about ten minutes, and then pouring into a closed vessel, and sweetening it when used. (*A. J. P.*, 1866, 441.)

Anhalonium.—Under the name of *Pellote* are used in Mexico for narcotic purposes certain cacti whose tops have entered commerce under the name of *Mescal Buttons*. In a mass of such cactus tops sent to the Pharmaceutical Institute of Leipzig

from Mexico as *pellote*, experts have recognized the products of *Anhalonium fissuratum*, *A. prismaticum*, *Lophophora Williamsii* (Lem.), Coult., and *L. Lewinii* (Henn.), Thompson. Moreover from *A. jourdanianum*, L., Lewin obtained traces of an alkaloid (*A. E. P. P.*, xxxiv.), so that there is little doubt but that various species of anhalonium are active and are represented in the commercial drug. The most important of these plants are *L. Lewinii* and *L. Williamsii*, which inhabit the valley of the Rio Grande in Mexico and are furnished with stems reaching about half an inch above the surface of the ground, surmounted by a top composed mainly of the blunt leaves of the plant, bent around a tuft, of from half an inch to an inch in diameter, composed of short yellow-white filaments or hairs. It is this top which constitutes the *mescal button*, which is from an inch to an inch and a half in diameter, one-fourth of an inch in thickness, with a convex under surface, a texture which is brittle and hard when dry, but becomes soft when moistened, a very bitter disagreeable taste, and an odor when moist which is peculiar and disagreeable, and is especially marked in the powdered drug. According to C. H. Thompson the buttons of *L. Lewinii* and *L. Williamsii* are readily distinguished by the fact that the surface of *L. Lewinii* is traversed by thirteen shallow narrow furrows giving the appearance of there being as many irregular or much broken ribs or obtuse ridges, while in *L. Williamsii* the furrows and ridges are eight in number and regular. These species, formerly referred to *Anhalonium*, belong to Coulter's genus, *Lophophora*, which is characterized by a flexible epidermis, its freedom from spines and tubercles and its segments not assuming the form of a projecting or leaf-like organ. (*Reports of Missouri Botanical Gardens*, 1898.)

In 1888, L. Lewin separated from *L. Lewinii* an alkaloid, *anhalonine*, which has the formula $C_{12}H_{15}NO_3$, and crystallizes in small white prisms, soluble in ether, alcohol, and chloroform. Subsequently, by treating the powdered buttons with 70 per cent. alcohol, filtering, alkalizing with ammonia, and consecutively employing chloroform and ether, Hefter (*Ber. d. Chem. Ges.*, 1896) separated from *L. Lewinii*, besides *anhalonine*, three alkaloids: *mescaline*, $C_{17}H_{17}NO_3$, in white needles melting at $151^\circ C.$; *anhalonidine*, $C_{12}H_{15}NO_3$, fusing at $160^\circ C.$, and *lophophorine*, $C_{13}H_{17}NO_3$. (See also *A. E. P. P.*, xl, 1898.)

Kander (*A. Pharm.*, 1899, vol. 237) has found that in commercial mescal buttons, besides the alkaloids already mentioned are two other bases, *pellotine* and *anhalamine*, so that Merck has offered as commercial products the following salts: *Anhalonine Hydrochloridum* cryst., *Anhalonidine Hydrochloridum* cryst., *Lophophorine Hydrochloridum* cryst., *Mescaline Sulphas* cryst., *Pellotine Hydrochloridum* cryst. According to the researches of Hefter, *pellotine*, $C_{13}H_{15}NO_3$, is contained exclusively in *L. Williamsii*, but as this cactus is present in most if not all of the commercial buttons it was naturally found by Kander in analyzing the commercial drug. Moreover, the correctness of the conclusion of Hefter is challenged by Merck's chemists, who, in the analysis of *L. Williamsii*, found the same quantity of the same alkaloids as is present in the true mescal button. For a description of these alkaloids see *M. R.*, 1898 and 1900. E. White (*J. P.*, xxv.) obtained *mescaline*, 1.16 per cent.; *anhalonidine*, 1.16 per cent.; *anhalonine*, 0.46 per cent.; *loph-*

ophorine, 0.14 per cent. *Anhaline*, $C_{10}H_{17}NO$, is an alkaloid crystallizing in colorless stellate prisms, which has been extracted from *L. fissuratum*.

From time immemorial the Kiowa Indians of the Rio Grande have used the mescal buttons for the purpose of producing intoxication during their religious ceremonies. Attention was first called to the peculiar cerebral action of the drug by D. W. Prentiss and Francis P. Morgan (*T. G.*, 1895), who found that from two hundred and fifteen to two hundred and thirty grains (14-15 Gm.) (four to five buttons) will produce a peculiar cerebral excitement attended with an extraordinary visual disturbance, characterized by an incessant flow of visions of infinite beauty, grandeur, and variety, of both color and form, often followed after a time by the seeing of monsters, grotesque faces, and gruesome shapes. During the intoxication there are dilatation of the pupil, muscular relaxation, and some slowing of the pulse. Loss of sense of time, partial anesthesia, weakened heart's action, great muscular relaxation, wakefulness, and in some cases nausea and vomiting also have been noted, but no distinct alteration of the respiration. These results have been confirmed by several observers.

A. Mogilewa (*A. E. P. P.*, 49, 137) found that mescaline, anhalonidine, anhalonine, lophophorine, and pellotine acted similarly in lessening the frequency and force of the isolated fever heart, varying simply in quantitative power. The most thorough research upon the anhalonium alkaloids is that of W. E. Dixon (*J. P.*, xxv.), whose report is somewhat marred by the fact that he does not state in his experiments which one of the alkaloids was employed; he simply affirmed that anhalonine and anhalonidine are identical in physiological activity, that lophophorine differs only in being more toxic, and that mescaline has a physiological action almost indistinguishable from that of its associated alkaloids. He finds that "the alkaloid" is not locally anesthetic; that increased salivation is one of the most characteristic symptoms of its action; that it rarely causes vomiting; that in therapeutic doses, in man at least, it produces constipation, but that in toxic dose it causes diarrhea and bloody stools; that no effect is produced by it on the blood; that its main circulatory effect is upon the cardiac muscle and contained ganglia, whereby it produces slowing of the heart, and causes in mammals a rise of arterial pressure; that it has no effect upon voluntary muscles; that it kills by action on the respiratory centres so that in man the most serious result of an overdose is rapid, shallow breathing, with a sense of suffocation; that upon the nervous system it acts most powerfully, influencing in the lower animals and especially in man the cerebral cortex, producing in the frog and to a lesser degree in the mammal, increasing loss of muscular power with heightened reflexes, believed to be due to spinal stimulation. The motor nerves appear to be again depressed rather than stimulated, since they are paralyzed when the drug is applied locally to them.

Experiments were performed by Dixon upon two human subjects, with the alkaloid, which was found to produce wide dilation of the pupils, with uncertainty of gait like that of alcoholic intoxication, tremors, and heightened reflexes although sensation was distinctly blunted. The psychological symptoms caused by the largest doses resemble somewhat those from *cannabis indica*; these

being, however, not only overestimation of time, sense of dual existence, and delirium, but also pronounced visual hallucinations with undulatory motion of light, similar to those seen in ophthalmic migraine, and a regular kaleidoscopic play of colors. There was also a very extraordinary effect upon hearing, each note produced by the piano becoming the centre of a "medley of other notes which appeared to me surrounded by a halo of color pulsating to the music." The alkaloid was excreted by the kidneys and acted somewhat as a diuretic. The dose of the alkaloid used by Dixon was three and eight-tenths grains (0.25 Gm.).

In Heffter's experiments *pellotine* was found to be physiologically feeble, $\frac{1}{15}$ grain (0.005 Gm.) causing only temporary stiffness in the legs of the frog, $\frac{1}{10}$ grain (0.01 Gm.) producing stiffness, heightened reflexes, strychnine-like tetanus, lasting from three to four days, ending in recovery. In man, from seven-tenths to nine-tenths of a grain (0.045-0.058 Gm.) produced only temporary sleeplessness with sense of weariness. Pilcz (*W. K. W.*, ix, 1896) has used *pellotine* as a caluminate in fifty-eight cases of *insanity* in doses of from one-third to one grain (0.021-0.065 Gm.). About half the cases were markedly affected, sleep coming on in from half an hour to an hour and a half after the hypodermic injection and continuing through the night. No disagreeable results and no collapse occurred, although Langstein is said to have seen collapse following the dose of seven-tenths of a grain (0.045 Gm.).

The value of mescal buttons as a remedial agent is doubtful; it has been employed to a slight extent in various forms of *neurasthenia* and *hysteria*, and is asserted by S. F. Landry (*T. G.*, 1888) to be especially valuable in cases of *asthma*. It has also been alleged to be useful in *neuralgia* and *rheumatic affections*. It may prove of value as a nerve stimulant in cases of *hypochondriasis* and similar states where there is a tendency to failure of the heart. Prentiss and Morgan give the dose of the crude drug as from seven to fifteen grains (0.45-1.0 Gm.); of the fluidextract, from ten to fifteen minims (0.6-0.9 Cc.); of the 10 per cent. tincture, from one to two teaspoonfuls (3.75-7.7 Cc.).

Anilina. *Aniline.* *Amidobenzene.* *Phenylamine.* ($C_6H_5NH_2$).—This is an organic base obtained from coal tar or more immediately from nitrobenzene. It was first discovered by Unverdorben, in 1826, among the products of the dry distillation of indigo, and was named by him *crystalline*. Fritzsche, who obtained it afterwards from indigo by another process, seems to have been the first to give it the name of aniline, from the Portuguese word *anil* (indigo). In 1837, Runge obtained three volatile principles from coal tar, which he named *kyanol*, *leucol*, and *pyrrhol*. Of these, kyanol was afterwards found by Hofmann to be identical with aniline, and leucol has been ascertained to be the same as *quinoline* (*chinoline*). Nitrobenzene is now the source whence most of the aniline of commerce is derived. Nitrobenzene, hydrochloric acid, and iron turnings, in equal weights, are introduced into a cast iron vessel, care being taken that the heat does not rise too high, when the following reactions take place:

The semi-solid mass which soon forms consists principally of ferrous chloride and aniline hydrochloride. This is distilled, after the addition of milk of lime, in a large cast iron cylinder, and the

distillate redistilled, the portion coming over between 175° C. (347° F.) and 190° C. (374° F.) being collected, and considered sufficiently pure for manufacturing purposes.

Properties.—Pure aniline is a thin colorless fluid, of an oily appearance; but as found in commerce it is generally more or less colored, and sometimes of a deep reddish brown. It has a peculiar, not disagreeable odor, and a pungent, aromatic, burning taste; its sp. gr. is 1.020 (Hofmann), 1.028 (Fritzsche). It is not solidified at -20° C. (-4° F.), boils at 182° C. (360° F.), and its vapors are condensed unchanged. It is slightly soluble in water, but dissolves in all proportions in ether, alcohol, methyl alcohol, acetone, carbon disulphide, and the oils, fixed and volatile. Though possessed of strong basic powers, it does not restore the color of reddened litmus, nor does it change turmeric. It changes, however, the violet color of dahlias to green. With the acids it forms soluble and readily crystallizable salts. It is inflammable, and absorbs oxygen from the air, becoming at first yellowish, afterwards reddish, and ultimately brown. A characteristic property is that it produces instantly a deep blue or purple color when brought into contact with chlorinated lime or other hypochlorite. Letheby described a very delicate test for this base. If a drop of a very weak solution of aniline sulphate be placed on a piece of clean platinum foil and touched with the negative pole of a galvanic battery the solution acquires a bluish, then a violet, and ultimately a pink color. (*P. J.*, Sept. 1862, 128.) It is a derived ammonia, having the group C_6H_5 in place of a hydrogen atom of the NH_3 molecule. It is hence often called *phenylamine*. The chief value of aniline at present is for the coloring matters derived from it, or rather from its derivative, *rosaniline*, contained in commercial aniline oil. Beautiful reds, purples, yellows, blues, and various other tints are obtained from it. For the mode of making inks from these colors, see *Roscoe and Schorlemmer's Chemistry*, vol. iii., part 3, pp. 318, etc. The following table shows the solubilities of aniline colors in water and alcohol:

Aniline color.	Per cent. soluble in water.	Per cent. soluble in alcohol.
Aurin	nearly insoluble.	40.00
Bismarck-brown	3.00	0.35
Corallin	2.00	0.50
Dahlia-blue	4.00	1.00
Eosin	2.00	1.00
Ethyl-orange	0.02	nearly insoluble.
Fuchsin	0.30	10.00
Gentian-violet	1.50	3.00
Luteolin	0.25	0.60
Magenta-red	0.20	2.50
Malachite-green	4.00	5.00
Manchester-yellow	2.00	0.15
Methylene-blue	3.00	1.50
Methyl-green	7.00	0.25
Methyl-violet	2.00	1.50
Safranin	0.60	0.40
Tropæolin OO	0.05	0.10
Vesuvium	2.00	0.20

—*Ph. Centralh.*, 1887, 385.

Aniline-black or *nigrosin* was discovered by Wolf in 1863. As it occurs in commerce it is a salt having the composition $C_{36}H_{29}N_3HCl$; if prepared from pure aniline it is of a deep blue color; if toluidine is present, it approaches a black in direct proportion to the amount of toluidine in it; it is very soluble in water, and ten grains dissolved in one fluidounce of water makes a good

nigrosin ink, which, however, should not be exposed to too strong a light, as all aniline inks fade in time. *Böttger's test* for detecting cotton in linens consists in dipping a portion of the texture in an alcoholic solution of aniline-red, then washing it with water till the washings are colorless, and putting it into an aqueous solution of ammonia. If cotton be present, its threads will be deprived of color, while the linen will continue of a bright rose-color. (See *A. J. P.*, Jan. 1866, 86.) Under the name of *aniline oil* a liquid is to be found in commerce which consists of a mixture of aniline, toluidine, xylidine, cumidine, and varying quantities of by-products found in the "tailings;" the boiling point ranges between 180° C. (356° F.) and 210° C. (410° F.), and the sp. gr. is also variable; it is used as a solvent for rubber, copal, etc.

Aniline-blue, or *triphenyl-rosaniline*, according to Iwanoff, possesses antimalarial properties similar to those of methylene blue. Five grains (0.32 Gm.) may be given in capsules three times a day.

Methyl-violet or *pyoktanin*, according to Liebreich, is a mixture of aniline compounds. The *pyoktaninum cœruleum* is methyl-violet, a mixture of the hydrochlorides of *penta-* and *hexamethyl-para-rosaniline*, $C_{24}H_{28}N_3Cl$ and $C_{25}H_{30}N_3Cl$, while *pyoktaninum aureum* is *auramine*, $C_{17}H_{24}N_3OCl$, or *amido-tetramethyl-di-amido-diphenylmethane*, known commercially as *auramine O*. *Apyonin*, introduced as an antiseptic similar to pyoktanin, is a yellow crystalline powder slightly soluble in cold water, soluble in alcohol. *Methylene blue*, $C_{16}H_{18}N_3SCl$, official as *Methylthionine Hydrochloridum* [p. 779], or *tetra-methylthionine-chloride*, is a derivative of diphenylamine, occurring in dark blue or reddish-brown bronze-tinged crystals, slightly soluble in water and alcohol.

Medicinal Properties.—The symptoms which are produced by the inhalation or ingestion of aniline are great prostration, heaviness in the head, giddiness, vomiting, violent neuralgic pains, and, if the dose has been large enough, cyanosis, coma with dilatation of the pupils, excessive perspiration, loss of reflexes and of voluntary movement, hurried weak pulse, rapid or irregular respiration, hæmoglobinuria, a peculiar discoloration of the skin, and, if the patient survives sufficiently long, jaundice with great increase in the biliary pigment of the urine. At the autopsy reported by Müller (*A. J. P.*, 1887), in a woman killed by the swallowing of about a fluidounce (30 Cc.) of aniline, the blood was chocolate brown, and gave the spectrum of methæmoglobin; the urine was free from sugar, albumin, or blood, but contained paramidophenol, and its distillates gave aniline reactions. The hæmoglobinuria is evidently connected with an extraordinary destruction of the red blood corpuscles, for in the case reported by Dehio (*A. J. P.*, 1888), in a woman who had taken one hundred and fifty grains (9.8 Gm.) of aniline, the red blood corpuscles fell from normal 5,000,000 per Cc. to 2,700,000 on the seventh, and 1,400,000 on the eleventh day. The globules were replaced slowly; on the eighteenth day their number was about one-third of the normal quantity.

The violent local effects which have been noticed as produced by some aniline dyes have probably been due to the presence of arsenic, which is used in the production of aniline and may remain as a contamination. See and Morau (*Méd. Mod.*, 1890) believe that *safranin* and *methyl-violet* are

practically free from poisonous properties; and Penzoldt, in a series of experiments, found that methyl-violet (0.05 Gm. per kilo) caused only local alterations,—viz., extensive gangrene of the skin; malachite-green (0.1 Gm. per kilo) caused motor paralysis and cramps, fatal on the ninth day; trimethyl-rosaniline (0.02 Gm. per kilo) caused similar symptoms; Bengal-rose (0.25 Gm. per kilo), phenyl-blue (0.1 Gm. per kilo), and methylene-blue (0.075 Gm. per kilo) caused no special symptoms.

In an elaborate research (B. G. T., Avril, 1891) Combemale determined that in the guinea-pig the fatal dose of methyl-blue, hypodermically given, is three decigrammes per kilo in weight and that the symptoms produced are great prostration, loss of responding to external irritants, anuria, and chocolate discoloration of the blood. For a physiological study of fuchsine and of pararosaniline, see Lyons Thesis, 1892, L. Dupays.

According to J. Stilling, the aniline dyes are possessed of active germicidal properties, the most active of them being the methyl-blue or violet, to which he has given the name of *pyoktanin*, certain auramines being next in rank. In Stilling's experiments, two parts of methyl-violet per thousand indefinitely prevented flour paste, milk, butter, lard, etc., from turning sour or rancid; while the solution of the strength of one to four thousand was sufficient to prevent the development of bacteria of putrefaction; the staphylococcus pyogenes aureus was found to be very susceptible to the germicidal power of the methyl-violet. Penzoldt also found that contact for one month with a concentrated solution of methyl-violet, malachite-green, trimethyl-rosaniline, and phenyl-blue was sufficient to kill the anthrax bacilli. Sée and Morau found that one part to twenty-five hundred of safranin and cyanin would destroy the organisms of diphtheria and of pus. Janicke, experimenting with the pathognomonic organisms of pus, of anthrax, of cholera, of typhus, and of pneumonia, found the activity of pyoktanin even greater than asserted by Stilling, and noticed a very remarkable difference in the susceptibility of different species of bacteria, making the further important observation that those bacteria that were most readily stained by the methyl-violet were most readily influenced by it. On the other hand, Valude states (Intern. Med. Congress, 1890) that immersion for at least one hour in a 1 per cent. solution of pyoktanin was required to effect the same result on pathognomonic bacteria as was caused in ten minutes by 1 to 4000 corrosive sublimate. The practical value in surgery of pyoktanin has been asserted by Stilling, by Sée and Morau, by Patterson, and by numerous other surgeons, but the remedy has not come into general use. It has even been used with alleged success superficially and parenchymatously in epithelioma and cancer, but the majority of the reports are in these affections unfavorable. In gonorrhoea, the strength used has varied from 0.2 to 2 per cent.; in ulcers, carbuncles, and cancers it may be employed pure after free incision, or be parenchymatously injected. Stilling uses the following preparations, insisting at the same time on the great necessity of having the methyl-blue absolutely pure: 1. *Pure methyl-violet*.—To be used as powder for large wounds and ulcers. 2. *Large pencils*.—For small wounds, burns, etc. For purulent cases the blue pencil is better than the yellow, on account of its greater antiseptic property. 3. *Small pencils*.—For application to the

eye, in cases of corneal ulcer, etc. 4. *Powders*.—Of 1 in 1000 strength for mild cases of conjunctivitis, and for more severe cases (blepharorrhoea) of 2 per cent. strength. These can also be used as a snuff in affections of the nasal mucous membrane. 5. *Ointments*.—In strength varying from 2 to 10 per cent. 6. *Solutions*.—Used in strengths of 0.1 to 1 per cent. The 1 in 1000 solution is to be employed for ordinary cases of conjunctivitis, keratitis, etc. The solutions should be filtered and kept in dark glass bottles, and changed every eight days. E. Vonder Goltz has proposed to substitute for methyl-violet a 10 per cent. alcoholic solution of aniline-red to be diluted according to needs of surgeon. (M. M., July, 1890.)

Aniline sulphate was employed as a nerveine by Fraser and Davis many years ago (M. T. G., Aug. 1865) with success, especially in the treatment of chorea, the dose being five grains (0.32 Gm.) three times a day, and the immediate results some headache and giddiness and staining of the mouth and nails. The practice was followed to some extent, but never gained the confidence of the profession.

Aniline Camphorate.—This is a compound which has been used by Tomaselli in doses of from eight to twelve grains (0.5–0.78 Gm.) a day as an antispasmodic. (P. J., June, 1887.)

Anilipyrine.—Gilbert and Yvon have given this name to a substance obtained by the melting together of one part of acetanilide and two parts of antipyrine. Anilipyrine is stated by Gilbert and Yvon to be extremely soluble in water and to be toxically very feeble. The fatal dose for the guinea-pig is 1.8 Gm. per kilo. Anilipyrine has been used by its introducers as an antipyretic and analgesic in migraine, neuralgia, rheumatism, etc. The dose is eight grains (0.5 Gm.) from two to four times a day.

Animé. *Gum Animé.*—The substance known at present by the name of animé is a resin supposed to be derived from the *Hymenaea Courbaril*, L., a leguminous tree of South America, though this origin was denied by Hayne. According to W. Hamilton, the resin exudes from wounds in the bark, and is found also underneath the surface of the ground, between the principal roots. (P. J., vi. 522.) It is in small irregular pieces, of a pale lemon-yellow color, sometimes inclining to reddish, more or less transparent, covered with a whitish powder, brittle and pulverizable, with a shining fracture, a weak but agreeable odor, and a mild, resinous taste. It softens in the mouth, adheres to the fingers when in powder, and readily melts with heat, diffusing its agreeable odor in an increased degree. It consists of two resins, one soluble, the other insoluble in cold alcohol, and of a small proportion of volatile oil. There is a variety of a darker color, less transparent, and with small cavities in the interior, in other respects resembling the preceding. Another variety is the East Indian, supposed to be derived from *Vateria indica*, L. (Fam. Dipterocarpaceae), but this never reaches American commerce. According to W. C. Ondaatje, the bark of this plant is in daily use by the natives of Ceylon to arrest the alcoholic fermentation of the juice of the Jaggery palm, *Caryota urens*, L., a favorite beverage. (P. J., 1883, 818.) Animé formerly entered into the composition of various ointments and plasters; but it is now used only as incense, or in the preparation of varnishes. The Brazilians employ it internally in diseases of the lungs.

Anidol.—This commercial product is a clear fluid with a garlic-like odor, lost on dilution. It is said to be an aqueous 1 per cent. solution of *trioxy-methylene* (*paraformaldehyde*) to which is added a little glycerin and an allyl derivative, which is not specified. Anidol is stated to be an antiseptic which is especially valuable because the 1 per cent. solution may be employed to sterilize tuberculous sputa without interfering with the morphology or staining properties of the bacilli. For disinfecting instruments, 1 to 5000 solution; for the mucous membrane of the nose and mouth, 0.5 per cent. solution; for wounds 0.25 per cent., gradually intensified—are recommended by Sedán.

Anisodus. *Anisodus luridus*, Link and Otto. (*Scopola lurida*, Dun.)—This is a Himalayan solanaceous plant in which Siebert has found *atropine* and *hyoscyamine*. (*A. Pharm.*, Feb. 1890; *P. J.*, March, 1890.)

Annatto. *Orleana*. *Annotta*. *Arnotta*. *Terre de la Nouvelle-Orléans*, Fr. *Orellana*, *Orlean*, G.—The coloring substance called *annatto*, *arnatta*, or *roucou*, is the reddish pulp surrounding the seeds in the fruit of *Bixa Orellana*, L. (Fam. *Bixaceæ*), a middle-sized tree native to Northern South America, but widely cultivated in tropical Asia and Africa. The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to settle. The mass which remains is dried and formed into flat cakes or cylindrical rolls. Another mode is to bruise the seeds, mix them with water, and allow the mixture to ferment. The coloring matter is deposited during the fermentation, after which it is removed and dried. In commerce there are two kinds of annatto, the Spanish or Brazilian, and the French, the former coming in baskets from Brazil, the latter in casks from French Guiana. The French, which is also called *flag annatto*, has a disagreeable odor, probably from having been prepared by the fermenting process; but is superior, as a dye stuff, to the Spanish, which is without any disagreeable odor. Annatto is of a brownish-red color, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odor, and a rough, saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow color, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. The South American Indians are said to produce directly from the annatto seeds, without fermentation, a color similar to and almost as brilliant as carmine. (*P. J.*, April, 1903.) For a proximate analysis of the leaves, see *Ap. Ztg.*, 1899, p. 35. It contains a peculiar coloring principle, to which Preisser, its discoverer, gave the name of *bixin*. This has the formula $C_{28}H_{34}O_5$, and when pure is a dark red somewhat crystalline substance. It is accompanied by a yellow coloring matter, *orellin*, which has been but little studied. (Wynter Blyth, *Foods: Composition and Analysis*, 507, London, 1882.) The chief uses to which annatto is applied are for dyeing silk and cotton orange-yellow, and for coloring cheese and butter. The color, however, which it imparts to cloth is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is employed to color plasters, and has occasionally been substituted for saffron. It is frequently adulterated with red ochre, powdered bricks, colcothar, farinaceous sub-

stances, chalk, calcium sulphate, turmeric, etc. The mineral substances, if present, will be left behind when the annatto is burned. (See, in reference to its adulteration, *P. J.*, xv. 199, 299, and 323; also xvi. 646.) *Tincture of annatto* is made by extracting 100 parts of annatto with 100 parts of water containing $\frac{1}{2}$ per cent. of potassium carbonate, and evaporating to 60 parts, mixing with 12 parts of alcohol and filtering.

Anona.—The seeds of *A. squamosa*, L., *Sugar Apple* or *Sweet Sop* of the West and East Indies, are said to be poisonous and to be used to kill lice, while the bark is a drastic cathartic. The seeds of *A. muricata*, L., *A. palustris*, L., and *A. spinescens*, Mart., are employed to poison fish and to exterminate destructive insects. (*Ph. Rev.*, Oct. 1896.)

Anthrakokali.—For an account of this preparation, which was introduced by Polya, see 16th ed. *U. S. D.*, p. 1711.

Anthrarobin. *Anthro-arobin*. $C_6H_4 \begin{Bmatrix} C(OH) \\ CH \end{Bmatrix}$

$C_6H_2(OH)_2$.—This substance, which is produced from commercial alizarin by reduction, was first described by Liebermann (*Ber. d. Chem. Ges.*, 1888), and proposed as a substitute for chrysarobin. It is a yellowish-white granular powder, almost insoluble in water and acidulated solutions, sparingly soluble in chloroform and ether, and readily soluble in alcohol and weak alkaline solutions. It mixes readily with fats to form ointments. It is a powerful deoxidizing agent, which seems to be less toxic than chrysarobin, and probably equally effective in the treatment of *diseases of the skin*, it having been used by G. Behrend, E. B. Bronson, Köbner, and other clinicians, with asserted advantage in those diseases for which chrysarobin is employed. Behrend recommends the following. *Solution of anthrarobin*: anthrarobin, 10 parts; borax, 8 parts; water, 80 parts. *Glycerite of anthrarobin*: anthrarobin, 10 parts; glycerin, 80 parts. (*Th. M.*, 1888.) As a topical application, the ointment or the alcoholic solution (each 10 per cent.) may be used.

Anthriscus. *Anthriscus Cerefolium* (L.), Hoffm. *Chærophyllum sativum*, Lam. *Scandix Cerefolium*, L., *Chervil*.—An annual European plant of the Fam. *Umbelliferae*, cultivated in gardens as a pot-herb, and naturalized in Eastern and Southern Pennsylvania. It has a strong agreeable odor, and a pungent, slightly bitterish taste. It contains a volatile oil of very feeble medicinal power, but it has been used as an emmenagogue and diuretic.

Antiarin.—A glucoside obtained from the upas tree, *Antiaris toxicaria* (see *Arrow Poisons*, p. 1397). It forms small needle-shaped crystals and is soluble in alcohol. Antiarin causes the frog's heart to be arrested in systole. Its toxicity towards the frog's heart is greater than any known member of the digitalis group, surpassing both strophanthin and digitoxin. It shows a marked antagonism upon the heart to hydrocyanic acid, the latter being able to re-establish rhythmic contractions in the heart arrested by antiarin. Antiarin also causes strong pulsations in the heart paralyzed by hydrocyanic acid. It is a muscle poison, causing first strong fibrillary contractions in the voluntary muscles, followed by a rapid and marked decrease in the irritability, with final loss. This paralysis is directly upon the muscle substance rather than upon the motor nerve endings. There is no similarity be-

tween the antiarin muscle curve and that of veratrine. Experiments with the crude drug had exactly the same results as the glucoside.

Antiarigenin, a destructive product of antiarin, shows a similar but distinctly greater action than the glucoside itself.

Antihydropin. *Pulvis Taracanae*.—The powdered Russian cockroaches (*Blatta lapponica*, *Blatta orientalis*) are asserted, in the dose of from ten to fifteen grains (0.65–1.0 Gm.), to be actively diuretic and useful in *dropsy*. Bogomolow (*Ph. Cb.*, July, 1879) found in them a crystalline principle, *antihydropin*, or *taracanim*. L. Reuter (*A. Pharm.*, 1889, 868–873) affirms that the discredit into which cockroaches have fallen is due to the indifferent quality of the powdered insects in the market, and gives tests for their purity.

Antimony Arsenate.—This is a heavy snow-white powder, containing 56 per cent. antimonious oxide (or antimony trioxide) and 44 per cent. arsenic oxide (or pentoxide). It is stated that it is used in Russia as an alternative in doses of one-fiftieth of a grain (0.0013 Gm.) four times a day. (*A. J. P.*, xlv. 301.)

Antimony Crocus. *Crocus of Antimony*. *Saffron of Antimony*.—This compound is formed during the deflagration of a mixture of equal weights of antimony trisulphide and potassium nitrate, to which one-twelfth of hydrochloric acid has been added. Fused crocus of antimony is in masses of a liver-brown color; the unfused is a saffron-brown insoluble powder, containing about four-fifths of trioxide, and one-fifth of trisulphide. It was formerly used in making tartar emetic.

Antimony, Diaphoretic. *Antimonium Diaphoreticum*. *Potassii Biantimonias*. *Antimoine diaphorétique lavé*, Fr.—This compound is directed, in the French Codex, to be formed by deflagrating in a red hot crucible, and keeping red hot for half an hour, a mixture of pure antimony with twice its weight of potassium nitrate, both being in fine powder. The product, washed with water and dried, is *washed diaphoretic antimony*. For improved process, see 14th edition of U. S. D., p. 1640. *Dose*, from two to three drachms (7.7–11.6 Gm.). This form of antimony is weak, variable, and rarely used.

Antimony Glass. *Vitrum Antimonii*.—This is prepared from antimony trisulphide by a partial roasting and subsequent fusion. Glass of antimony is in thin irregular pieces, which have a vitreous fracture, and a metallic steel-gray lustre. When well prepared, it is transparent, and, upon being held between the eye and the light, appears of a rich orange-red or garnet color; but if of inferior quality it is black and opaque. It is hard and brittle, and rings when struck with a hard substance. It is insoluble in water, but it is readily rendered soluble by acids and strong solution of potassium bitartrate, with the exception of a few red flocculi. Its essential constituents are the trioxide and trisulphide, united in variable proportions. Sometimes glass of lead is sold for glass of antimony, a fraud readily detected by the difference between the two substances in specific gravity, glass of lead having a density of nearly seven, while that of glass of antimony is not quite five. Glass of antimony is an active antimonial; but, owing to its variable composition and unequal operation, it is very seldom used.

When the levigated powder is mixed with one-eighth of its weight of melted yellow wax, and the mixture roasted over a slow fire, with constant

stirring, until it ceases to exhale vapors, a coal-like pulverizable mass is formed, the *cerated glass of antimony* of the old Edinburgh Pharmacopœia.

Antimony Iodide. SbI_3 . *Antimonii Iodidum*. *Antimony Triiodide* or *Teriodide*.—According to W. Copney of London, this iodide may be conveniently prepared by gently heating, in a Florence flask, metallic antimony and iodine, in the proportion of one atom to three. The elements combine with sudden heat and liquefaction, and, upon the withdrawal of the heat, the iodide formed solidifies, and is removed by breaking the flask. Antimony iodide, as thus prepared, forms a somewhat crystalline, foliated mass, which, when pulverized, yields a deep orange-red powder. By the action of water it is decomposed. It has been tried as an alternative in doses varying from one-fourth of a grain to a grain (0.016–0.065 Gm.), given in pill.

Antimony Sulphide. *Antimonium Nigrum*, Br. 1864; *Black Antimony*. (*Prepared Sulphuret of Antimony*, Br.) *Stibium Sulfuratum Crudum et Lavigatum*, *Antimonium Crudum*, *Sulfuretum Stibicum*; *Artificial Sulphuret of Antimony*; *Sulfure d'Antimoine du commerce*, Fr. Cod.; *Antimoine sulfuré*, *Antimoine cru*, Fr.; *Stibium sulfuratum nigrum*, P. G.; *Schweiflantimon*, *Schweifelspiessglanz*, G.; *Antimonio crudo*, Sp.; *Antimonii Sulphidum*, U. S. 1890. *Antimony Trisulphide*. Sb_2S_3 ; 334.09.—“Native antimony sulphide, purified by fusion and as nearly free from arsenic as possible.” U. S. 1890.

Preparation.—The antimony sulphide which is found in commerce is obtained from the native sulphide, called *antimony ore*, by different processes of purification, the following being an outline of that generally pursued. The ore is placed in melting pots in a circular reverberatory furnace, and these are made to connect, by means of curved earthen tubes, with the receiving pots, situated outside the furnace. This arrangement affords facilities for removing the residue of the operation, and allows of the collection of the melted sulphide without disturbing the fire, and, consequently, without loss of time or fuel. In the U. S. Pharmacopœia 1890, it was directed to be melted in order to purify it from infusible substances; in the British, to be reduced to fine powder, to fit it for pharmaceutical use. In order to bring it to this state, it should be submitted to the process of levigation. (See *Antimonium Nigrum Purificatum*, p. 153.) Much of the “Black Antimony” of commerce has been shown by Warder to contain no antimony whatever, but to be simply powdered coal and marble, and such can be easily distinguished by a rough test, as follows: Fill a dry, tared one-ounce bottle with the powder; after shaking it down it will be found that it will hold two and a quarter ounces of powdered black antimony, but only one and a quarter ounces of powdered coal. (*Proc. A. Ph. A.*, 1885, 479; see also S. W. McKeown's paper, *Proc. Ohio State Pharm. Assoc.*, 1885.)

Properties.—Antimony sulphide is mostly prepared in France and Germany. It is called, in commerce, antimony, or *crude antimony*, and occurs in fused conical masses, denominated loaves. “Steel-gray masses of a metallic lustre and a striated crystalline fracture, forming a black or grayish-black, lustreless powder, without odor or taste, and permanent in the air. Insoluble in water or alcohol, but soluble in hydrochloric acid with the evolution of hydrogen sulphide. At

a temperature below a red heat, the Sulphide fuses to a dark brown liquid. If 1 Gm. of the powdered Sulphide be digested and finally boiled with 10 Cc. of hydrochloric acid, it should dissolve without leaving more than 1 per cent. of residue. This acid solution, completely deprived of hydrogen sulphide by boiling, yields, when added to water, a white precipitate, which is soluble in a solution of tartaric acid. After the separation of the precipitate by filtration, the filtrate yields an orange-red precipitate with hydrogen sulphide test-solution." U. S. 1890. The quality of the sulphide cannot well be judged of, except in mass; hence it ought never to be bought in powder. Arsenic, which is often present in considerable quantities, may be detected by the usual tests for that metal. (See *Arseni Trioxidum*, page 197.)

The official antimony sulphide is a trisulphide consisting of two atoms of antimony and three of sulphur. When prepared by pulverization and levigation, it is in the form of an insoluble powder, without taste or odor, usually of a dull blackish color, but reddish brown when perfectly pure. By exposure to the air, it absorbs, according to Buchner, a portion of oxygen, and becomes partially converted into trioxide.

Uses.—This preparation is very uncertain in its operation, and ought not to be used in practical medicine. It has, however, been employed as a diaphoretic and alterative in *scrofula*, *glandular obstructions*, *cutaneous diseases*, and *chronic rheumatism*. It is used in the United States solely in veterinary practice. The dose is from ten to thirty grains (0.65–2.0 Gm.), to be given in powder or bolus.

Antimony Trichloride. *Butter of Antimony.* $SbCl_3$.—Prepared by subliming antimony sulphide with mercuric chloride, by the action of dry chlorine on the sulphide or metal, or by dissolving the sulphide in hydrochloric acid and concentrating the solution of the chloride, which is usually colored by contamination with iron, but by distilling the product the pure chloride will finally pass over, the distillate solidifying in a mass of fine white crystals. It forms a deliquescent, soft mass, known as butter of antimony which melts at $72^\circ C$. and boils at $223^\circ C$. It is very hygroscopic and corrosive. The addition of water produces the oxychloride known, when dry, as *powder of Algaroth*. A solution was recognized in the Br. Ph. 1885, and is used in medicine as a caustic. It is extensively used to give a bronze surface to iron and steel ware.

Antinonnin.—According to Harz and von Miller, this yellowish pasty compound is *potassium ortho-di-nitro-cresolate*. It is said to be actively germicidal, odorless, and poisonous. On account of its being very effective, non-volatile, and inexpensive, it has been highly recommended for spraying plants, etc., when attacked with mildew or other vegetable parasites: 1 to 2000 in soap solution may be used. It stains bright yellow.

Antipyrine Benzoate.—*Benzopyrine*, $C_{11}H_{12}N_2O.HC_6H_5O_2$, made by adding antipyrine to a boiling solution of benzoic acid. It is in the form of a yellow liquid, practically insoluble in hot and cold water but soluble in alcohol and ether.

Antipyrine Tannate.—This is described as a yellow powder, insoluble in water, soluble in alcohol, and containing 37 per cent. of antipyrine. It is stated that it may be made by adding concentrated aqueous solutions of its constituents in the proportion of fifty parts of antipyrine to twenty-

eight and a half parts of tannic acid. It has been specially recommended on account of its tastelessness, but is probably not an eligible preparation.

Antiseptin. *Asepsin.* *Monobromacetanilide.* *Parabromacetanilide.* $C_6H_4Br.NH(C_2H_5O)$.—This substance has been used by Cattani as an antipyretic and analgesic (G. M. P., 1890), but as such seems to be dangerous. Cattani affirms it to be a valuable antiseptic. Dose, from six to seven grains (0.40–0.45 Gm.). Another compound, called antiseptin (or *antiseptin*), has been exploited as *iodo-boro-thymolate of zinc*, which, according to Squibb, is a mixture of zinc sulphate, boric acid, zinc iodide, and thymol. (Ph. Post, 1893, 106.)

Antiseptol.—Under this name Yvon has recommended *cinchonine iodosulphate* as a substitute for iodoform. It contains 50 per cent. of iodine. Yvon prepares it as follows. Twenty-five grammes of the cinchonine sulphate are dissolved in two thousand grammes of water; to this solution is added sufficient of a solution of iodine to cause a precipitate, avoiding an excess; this solution is made by dissolving ten grammes each of iodine and potassium iodide in one thousand grammes of water. The precipitate is placed on a filter and well washed with water until the washings are free from iodine, and it is then air-dried. (Nouv. Rem., July, 1890.)

Antispasmin. $C_{23}H_{26}NO_3Na + 3C_6H_4(OH)COONa$.—In this compound 1 molecule of *narcaine-sodium* is considered to have united with 3 molecules of sodium salicylate. This white, slightly hygroscopic powder contains about 50 per cent. of narcaine, and is said to have the advantage over the other narcaine preparations of readily forming with water a somewhat permanent solution. According to Demme, it is a valuable hypnotic and analgesic, especially advantageous in painful cramps. It has also been recommended for *whooping cough*. Dose, from one-half to one grain (0.032–0.065 Gm.).

Antithermin. *Phenylhydrazin-lävulinic acid.* $C_6H_5.N_2H = C(CH_3).C_3H_6O_2$.—This substance, which is obtained by the action of phenylhydrazin upon *acetopropionic acid*, occurs in colorless crystals, insoluble in cold water, soluble in ether and hot alcohol, melting point $108^\circ C$. ($226^\circ F$). It was first proposed in 1887 by Nicot as an antipyretic, and it has been especially experimented upon by Drobner (W. M. P., 1892, 540), who finds it very active in doses of from eight to ten grains (0.5–0.65 Gm.). It produces, however, pallor, cephalic distress, excessive sweating, and other evidences of vasomotor depression, which require great caution in its use, and not more than three grains (0.2 Gm.) should be given.

Antitussin.—*Di-fluor-di-phenyl*, $(C_6H_4F)_2$, occurs as colorless crystals melting at $87^\circ C$. ($189^\circ F$). It forms the active ingredient of antitussin, which has been strongly recommended by Max Heim (B. K. W., Dec. 1899) in the treatment of *whooping cough*. It is used as an ointment consisting of five parts of di-fluor-di-phenyl, ten parts of vaselin and eighty-five parts of lanolin. For a child a year old, about one-half drachm (2 Gm.) is slowly rubbed into the skin daily on the back, chest, and abdomen, about a drachm (3.9 Gm.) being used for a child five years old.

Anusol.—A proprietary suppository, alleged to contain a bismuth compound of *iodo-resorcin-sulphonic acid*, has been recommended for the treatment of *hemorrhoids*. Zinc oxide, resorcinol, bismuth oxyiodide, balsam of Peru, and cacao butter are the ingredients. (West. Drug., 1898, 75.)

Anytoles.—These are proprietary preparations in which substances like phenol, cresol, volatile oils, camphors, etc., are dissolved in water by means of *anytin*, a substance formed by the action of sulphuric acid on various mineral oils, resin oils, and hydrocarbons. The ammonia salt of the hydrocarbons, containing 10 per cent. of chemically combined sulphur, has been found the most useful solvent. The following are some of the anytoles which have been prepared: *Phenol-anytole*, *cresol-anytole*, *meta-cresol-anytole*, *creosote-anytole*, *guaiacol-anytole*, *benzene-anytole*, *eucalyptol-anytole*, *peppermint-anytole*, *wintergreen anytole*, *turpentine-anytole*, *camphor-anytole*, and *iodine-anytole*—all containing a good proportion of the active ingredient. It has been claimed for these anytoles that they are superior in bactericidal power to the disinfecting substances they contain. Wilhelm Koelzer has strongly commended meta-cresol-anytole in the treatment of *erysipelas*.

Apium. *Apium graveolens*, L. (Fam. Umbelliferae.) March, Céleri, Fr. Sellerie, Eppich, G. The ordinary *celery* of the gardens is believed by some persons to possess antispasmodic properties, and has been used as a nerve stimulant. It contains *apiol*, although in much less quantity than does parsley.

Apium nodiflorum (L.), B. & H. (*Sium nodiflorum*, L.) *Water parsnip*.—This is a perennial umbelliferous aquatic European plant, growing also in the southern section of the United States. It is commonly considered poisonous; but the fresh juice has been used by Withering and others, in the dose of three or four ounces every morning, for scrofulous *lymphadenitis* and obstinate skin diseases.

Apium petroselinum, L. *Petroselinum*, U. S. 1870. Ache, Persil, Fr. Petersilke, G. Prezzemolo, It. *Petroselinum sativum*, Hoffman, Umb., i. t. 1, f. 2.—Parsley is an umbelliferous plant having a biennial root, with an annual, round, furrowed, jointed, erect, branching stem, about two feet in height. *Parsley root* is spindle-shaped, about as thick as the finger, externally white, and marked with close annular wrinkles, internally fleshy and white, with a yellowish central portion. It has a pleasant odor and a sweetish, slightly aromatic taste, but loses these properties by long boiling and by time.

The plant is a native of Sardinia and other parts of Southern Europe, is naturalized in salt marshes on the coast of California, and is cultivated everywhere in gardens. All parts of it contain a volatile oil, to which it owes its odor and mainly its taste, as well as its use in seasoning. This oil consists of a hydrocarbon, $C_{10}H_{16}$, and *apiol*, $C_{12}H_{14}O_4$, crystallizing in white silky needles, which fuse at $30^{\circ} C.$ ($86^{\circ} F.$), and boil at about $300^{\circ} C.$ ($572^{\circ} F.$), subliming with partial decomposition. Braconnot obtained from the herb a peculiar substance, resembling pectic acid in appearance, which he named *apiin*. It is procured by boiling the herb in water, straining the liquor, and allowing it to cool. The *apiin* then forms a gelatinous mass, which requires only to be washed with cold water. Von Gerichten (*Ber. d. Chem. Ges.*, 1876, 1121) found that by repeated dissolving of this gelatinous mass in alcohol and precipitation by water it could be purified and then obtained from concentrated alcoholic solution in silky needles of the formula $C_{27}H_{32}O_{16}$. Joret and Homolle found the seeds to contain a volatile oil, a crystallizable fatty matter, pectin, what

they believe to be the *apiin* of Braconnot, chlorophyll, tannin, a coloring matter, extractive, lignin, various salts, and, in addition to these, a peculiar substance to which they gave the name of *apiol*. This is a yellowish oily liquid, not volatile, heavier than water, of a peculiar and tenacious odor distinct from that of the plant, and an acrid pungent taste. It is inflammable, insoluble in water hot or cold, very soluble in alcohol, and dissolved in all proportions by ether and chloroform. It is analogous to the fixed oils, but is not chemically modified by the alkalies. It contains no nitrogen.

According to L. Wolff (*A. J. P.*, 1877, 2), commercial *apiol* is merely the oleoresin; he proposes a very simple process for true *apiol*. Powdered parsley seed is exhausted with petroleum benzin, and the liquid is spontaneously evaporated; the residue is a mixture of fixed oil, wax, and *apiol*; the *apiol* alone being soluble in alcohol can easily be separated by repeated washings with strong alcohol; the washings evaporated over a water bath at a gentle heat leave as a residue "true *apiol*." L. Ough (*C. D.*, 1894, 17) obtains *apiol* by percolating freshly powdered parsley seeds with alcohol, recovering the alcohol from the percolate by distillation, and separating the oily residue from the deposited waxy solid.

Ciamician and Silber (*Ph. Post*, 1888, 391) have investigated *apiol*, and state that the pure substance occurs in white crystals having the composition $C_{12}H_{14}O_4$, melting at $30^{\circ} C.$ ($86^{\circ} F.$), and boiling at $294^{\circ} C.$ ($561^{\circ} F.$). *Isapiol*, *apiolic acid*, *apiolaldehyde*, and *apion* are decomposition products. They state that *isapiol* has physiological properties resembling those of pure *apiol*.

H. C. Whitney (*N. R.*, January, 1880) proposed to change the name of commercial *apiol*, and call it *oil of parsley seed*. He believed that the volatile oil of parsley seed is the active and emmenagogue principle, and obtained it by distilling the freshly powdered seed with salt water. The yield is 4.27 per cent. of an oil which corresponded closely with Joret and Homolle's *apiol*. Von Gerichten (*Ber. d. Chem. Ges.*, 16, 17) obtained besides the peculiar terpene, *parsley camphor*, which he thinks is alone entitled to the name of *apiol*. He gives its melting point as $30^{\circ} C.$ ($86^{\circ} F.$), boiling point $300^{\circ} C.$ ($572^{\circ} F.$), and sp. gr. 1.015.

Parsley root in the recent state is said to be aperient and diuretic, and is occasionally used in *nephritic* and *dropsical affections*. The juice of the fresh herb and the seeds have been employed in *intermittents*. According to Joret and Homolle, *apiol* produces, in the dose of about fifteen grains (1 Gm.), a slight cerebral excitation without unpleasant effects of any kind, and, in double or quadruple the quantity, a species of intoxication, with giddiness, morbid sights and sounds, and frontal headache. They found it to cure *intermittents*, but subsequent observations have shown that it has very little antiperiodic power. Joret and Baillet commend it in *amenorrhœa* and *dysmenorrhœa*, in the dose of about four grains (0.26 Gm.) morning and evening; in the former affection in anticipation of the menstrual period, in the latter during its continuance. Experience has confirmed its value as an emmenagogue, but it is best used in a single dose of fifteen grains (1 Gm.), given in capsules, at the time of the molimen. *Isapiol* is said to produce headache and temporary intoxication, and to have no practical advantages over *apiol*.

Aplopappus. *Aplopappus Baylahuen* (*Haplopappus Baylahuen*, Remy). *Hysterionica Baylahuen*.—This composite herb is a native of Chili, where it is said to be relied upon as a stimulant in *flatulent dyspepsia* and *chronic inflammation* with *hemorrhage* of the lower bowels. It has been analyzed by H. H. Rusby (*A. J. P.*, 1890, 488), and later by H. Kahn (*A. J. P.*, 1891, 377). The former found a volatile oil, a fatty oil which had the specific odor of the plant, a brown acid resin of sharp taste, and tannin. The latter determined the percentage of volatile oil as 6.65, and of resin as 21.15. He also considers that this resin is a mixture of four different resins. G. Baille asserts (*B. G. T.*, Feb. 1889) that the remedy is valuable not only in *dysentery*, but in genito-urinary catarrhs, and also as a stimulating expectorant. One-half to one tablespoonful (7.5–15 Cc.) of a strong decoction, one part to five, may be given every two hours; or the fluidextract, *dose*, from five to twenty minims (0.3–1.3 Cc.).

Apocodeine Hydrochloride.—Apocodeine has been investigated physiologically by W. E. Dixon (*B. M. J.*, 1902) who found that it lowered blood pressure by dilating the blood vessels and increased the intestinal peristalsis. Foy and Combe-male have both employed it hypodermically as a laxative with pleasing results. Thirty minims (1.8 Cc.) of a 1 per cent. solution may be injected deeply into the muscles.

Apolysin. *Monophenetidin Citrate*. $C_9H_9O_4$ (COOH) $_2$ CO.NH.C $_9$ H $_9$ OC $_2$ H $_5$.—A compound of citric acid and parphenetidin. It is a crystalline, yellowish-white powder of peculiar odor and taste, less acid than citric acid. Its melting point is 72° C. (161.6° F.). It is soluble in cold water (1 in 25), alcohol, and glycerin, and in concentrated sulphuric acid without change of color. The solution in nitric acid turns a pale orange color. The aqueous solution is not clouded by silver nitrate, nor the acid solution by hydrogen sulphide. R. Seifert (*D. M. W.*, xxi. 1895) asserts that in *doses* of from eight to twenty-four grains (0.5–1.6 Gm.), three or four times a day, it is a valuable remedy as an antipyretic in various febrile diseases, and possessed of great power as an analgesic, similar in range of usefulness to acetphenetidin, but free from poisonous properties or disagreeable after effects.

Aquilegia. *Aquilegia vulgaris*, L. *Columbine*. A perennial herbaceous plant of the Fam. Ranunculaceæ, indigenous to Europe, but cultivated in our gardens. All parts of it have been medicinally employed. The root, leaves, and flowers have a disagreeable odor, and a bitterish acid taste. From the small black shining seeds A. T. De Rochebrune (*Toxicol. Africaine*, i. 1897) has separated an alkaloid, *aquilegine*, in the form of long, prismatic, slightly iridescent crystals. The same investigator found that the extract of the plant produces in the lower animals symptoms very similar to those caused by aconite. At one time considered diuretic and diaphoretic, columbine is not at present used in practical medicine.

Aralia. *Aralia nudicaulis*, L. *False Sarsaparilla*. *Wild Sarsaparilla*. *Shotbush*. *Small Spikenard*. *Wild Licorice*. *Racine d'aralie nue*, *Petitnard*, Fr. *Nackte Araliencurszel*, G.—This plant is an indigenous perennial, belonging to the Fam. Araliaceæ. It grows from Canada to the Carolinas, inhabiting shady and rocky woods, and delighting in a rich soil. The root is horizontal, creeping, sometimes several feet in length, about as thick as the little finger, more or less twisted, of a

yellowish-brown color externally, of a fragrant odor, and a warm, aromatic, sweetish taste. Alpers and Murray (*Proc. A. Ph. A.*, 1897, 182) found in it 3.05 per cent. of resin, 0.33 per cent. of oil, tannin, an acid, albumen, mucilage, and cellulose.

W. C. Alpers (*A. J. P.*, Aug. 1899) states that the sesquiterpene of *Aralia nudicaulis* is distinct from isomeric compounds and proposes the name of *araleine* for it. He states that the volatile oil consists principally of this sesquiterpene, C $_{15}$ H $_{24}$, and an alcohol, C $_{15}$ H $_{25}$.OH with a small quantity of azulene. The sesquiterpene has a specific gravity of 0.9086 at 20° C. (68° F.), boiling point, 270° C. (518° F.); [a]_D equals –7 to –8; N_D equals 1.49936. It forms oily compounds with HCl and Br, and derivatives with nitrous acid. Treated with hydrochloric-acetic acid it forms a compound of a permanent blue color. Chloroform and sulphuric acid produce a purple-red color; acetic acid and sulphuric acid a wine-red color. *Aralia racemosa*, L. (*American spikenard*), is distinguished by its herbaceous widely branched stem, which is furnished with leaves whose leaflets are heart-ovate, pointed, doubly serrate, slightly downy, and also by its blackish or dark purple fruit being in very numerous umbels, and so clustered as to make a large compound panicle. Its rhizome is short, two or more inches thick, furnished with closely placed, large, nodose stem-scars, and numerous roots from one to two feet long, which are much branched below. In odor and taste it resembles *A. nudicaulis*, but is more spicy. *Aralia hispida*, Vent. (*Bristly Sarsaparilla*, *Dwarf Elder*), closely resembles *A. nudicaulis*, but is distinguished by its larger stem, which is also bristly and leafy. Its root has been used as a diuretic in *dropsy*. (*A. J. M. S.*, xix. 117.) For microscopic description with illustrations of the root of *A. nudicaulis*, by E. S. Bastin, see *West. Drug.*, 1885, 314; also Burt E. Nelson in *M. R.*, 1899, p. 441.

The roots of *Aralia racemosa* and *A. nudicaulis* have been used especially in domestic practice for their gently stimulant diaphoretic and alterative action, chiefly in *rheumatic*, *syphilitic*, and *cutaneous affections*, in the same manner and dose as genuine sarsaparilla. W. R. Monroe (*A. J. P.*, Oct. 1898) found in the rhizome of the *Aralia californica*, S. Wats., a small amount of a pale yellow, very aromatic, volatile oil, but failed to detect saponin.

Aralia spinosa, L. *Angelica-tree*. *Hercules club*. *Toothache-tree*. *Prickly Elder*. *Prickly Ash*.—The name "*prickly ash*" should be dropped, as it belongs properly to a species of *Xanthoxylum*. *Angelica tree* is an arborescent shrub which grows in Southeastern North America. The bark, root, and berries are medicinal.

The bark (*Ecorce d'aralie épineuse*, Fr.; *Dornige Aralienrinde*, G.), as in the shops, is usually in small quills or half quills, from two or three lines to half an inch in diameter, thin, fibrous, grayish externally, and armed with prickles or the remains of them, yellowish within, of an odor somewhat aromatic, and a bitterish taste, which becomes slightly acid on chewing, and leaves a lasting sense of pungency upon the tongue. It yields its virtues to boiling water. C. W. Elkins found in the bark starch, glucose, gum, pectin, two acid resins, volatile oil in small quantity, and what he believed to be an uncrystallizable alkaloid. (*A. J. P.*, Aug. 1880.) L. H. Holden (*A. J. P.*, 1880, 390) found along with tannin and other ingredients a glucoside, *aralim*. J. K.

Lilly (A. J. P., 1882, 433) obtained the glucoside by adding ether to the alcoholic extract. The glucoside is thrown out, then dissolved in water, precipitated first with neutral lead acetate and then the filtrate with basic acetate. This precipitate decomposed with hydrogen sulphide yields the glucoside, which is recrystallized out of alcohol. Decomposed by boiling with diluted hydrochloric acid, it yields sugar and *araliretin*. The virtues of *Aralia spinosa* are those of a stimulant diaphoretic. According to Elliot, an infusion of the recent bark of the root is emetic and cathartic. The remedy is used in *chronic rheumatism* and *cutaneous eruptions*, and in some parts of the South has been employed in *syphilis*. Pursh states that a vinous or spirituous infusion of the berries is remarkable for relieving rheumatic pains, and a similar tincture is said to be employed in Virginia with advantage in violent *colic*. The pungency of this tincture has also been found useful in relieving *toothache*. The bark is best administered in decoction.

Archidendron. *Archidendron Vaillantii*.—The bark and black beans of this leguminous plant of New South Wales are said to be an active paralyzant to the motor side of the spinal cord. (Bancroft, *Proc. Roy. Soc. N. S. W.*, 1886.)

Areca Nut. *Semen Arecae. Betel Nut. Noix d'Arece, Fr. Arekanüsse, Betelnüsse, G.*—The *Areca Catechu*, L., is an East India palm. The fruit, which is about the size and shape of a small egg, and of an orange-yellow color, contains the nut embedded in a fibrous, fleshy envelope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, the betel nut of commerce, is of a roundish-conical shape, rather larger than a chestnut, externally of a deep brown, diversified with a fawn color, so as to present a reticular appearance, internally brownish red with whitish veins, very hard, of a feeble odor when broken, and of an astringent, somewhat acrid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin, and various saline substances. Flückiger found that the tannic acid gives a green color turning to brown with ferric salts. (*Pharmacographia*, 671.) It yields its astringency to water, and in some parts of Hindostan an extract is prepared from it having the appearance and properties of catechu. A red coloring matter known as *Areca red* is extracted, probably resulting from the decomposition of a tannin. It is insoluble in cold water and ether, soluble in boiling water and alkaline liquids, out of which it is precipitated by acids. E. Jahns (*Ber. d. Chem. Ges.*, 1888, 3404) has found three alkaloids in areca nut: 1. *Arecoline*, $C_8H_{13}NO_2$, identical with the *arekane* of Bombalon. 2. *Arecaidine*, $C_7H_{11}NO_2 + H_2O$, which occurs in permanent, colorless crystals, soluble in water, insoluble in absolute alcohol, ether, chloroform, and benzene. 3. An alkaloid which exists in such small quantities that sufficient was not obtainable for close examination. On heating arecoline with strong hydrochloric acid to $150^{\circ} C.$ ($302^{\circ} F.$) it is decomposed into methyl chloride, CH_3Cl , and *arecaidine*, $C_7H_{11}NO_2$. This latter base forms colorless plates, stable in the air, fusing at from 223° to $224^{\circ} C.$ (433.4° – $435.2^{\circ} F.$), easily soluble in water, difficultly soluble in strong alcohol, and insoluble in ether and chloroform. *Arecaidine* has been shown to be *methyltetrahydronicotinic acid*, and has been made synthetically from nicotinic acid. The third alkaloid of Jahns is probably *guvacine*, $C_8H_9NO_2$, of which

the methyl derivative is the base *arecaidine* before mentioned. Immense quantities of areca nut are consumed in the East, mixed with the leaves of the betel pepper (*Piper Betle*, L., *Chavica Betle* (L.), Mig.) and with lime, forming the masticatory so well known by the name of *Betel*. The red color which this mixture imparts to the saliva and the excrements is owing to the areca nut, which is also powerfully astringent, and, by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. (See *N. R.*, 1876, 71.) Marmé affirms that arecoline resembles muscarine in its action upon the heart, and is a respiratory depressant. According to Jahns (*B. G. T.*, 1889), *arecaidine* is the active principle of the areca nut, and a powerful *tonicide*, resembling in its action pelletierine. It is an active poison, half a grain (0.032 Gm.) sufficing to kill a rabbit in a few moments. Its general action seems to be like that of muscarine, but it influences the respiration as well as the heart, causes tetanic convulsions, and has an extraordinary influence in increasing intestinal peristalsis. Locally applied, or when given internally, it contracts the pupils. (*Ph. Ztg.*, Feb. 1889.) *Arecaidine* is said to resemble in its physiological action methyl-nicotinic acid.

Arecoline hydrobromide, a commercial salt, according to the experiments of Fröhner, is more powerful as a stimulant to the salivary glands than pilocarpine, and more active as a laxative than eserine. It is especially commended by veterinarians in the *colic* of horses, given subcutaneously in the dose of from five to ten grains (0.32–0.65 Gm.). In human medicine it has been used in the dose of from one-fiftieth to one-tenth grain (0.004–0.006 Gm.) against the *tape worm* and as a myotic. As pointed out by Lavagna in 1895, arecoline is a very active myotic, and the hydrobromide has been considerably used. A one-half to one per cent. solution produces a violent myosis, which reaches its maximum in about ten minutes and begins to subside in half an hour. It is affirmed that the action of arecoline in intensity is superior to that of pilocarpine and inferior to that of eserine. It is especially claimed by various ophthalmologists that though in *glaucoma* its action is very transient, it produces a more considerable reduction of the intraocular pressure than can be obtained either with pilocarpine or eserine. It may cause considerable irritation but does not injure the continuity of the epithelium.

In India the areca nut has long been used as a vermifuge, the dose being a teaspoonful of the freshly grated nut, and its value against the *tape worm* has been confirmed by various European and American practitioners. The usual dose is from one to two drachms (3.9–7.7 Gm.). In this country the nut has also been used for the making of a hard charcoal, employed as a basis of tooth-powder.

Argemone. *Argemone mexicana*, L. *Prickly Poppy. Argémone*, Fr. *Stachelmohn*, G.—An annual plant, belonging to the Papaveraceæ, growing in our Southern and Western States, Mexico, the West Indies, Brazil and in many parts of Africa and Southern Asia. The whole plant abounds in a milky, acrid juice, which becomes yellow on exposure, and has been used as a local application in obstinate *cutaneous diseases*, especially that affection known in Upper India as *dhad*, and also in cases of *warts* and even *chancres*. The small,

round, black, and roughish seeds are emetic in two drachms (7.7 Gm.), or in smaller dose purgative. They contain a light yellow, transparent, fixed, drying oil which, according to Charbonnier, retains its fluidity at 5° C. (41° F.), and is entirely soluble in five to six measures of alcohol at 32.2° C. (90° F.). Flückiger assigns to the oil a sp. gr. of 0.919, and finds that it is not soluble in six parts of alcohol. According to Charbonnier it is gently cathartic in doses of from fifteen to twenty-five drops (0.75–1.25 Cc.); in larger doses emetic. (*J. P. C.*, May, 1868.) The alleged presence of morphine in *Argemone mexicana* has been disproven by J. O. Schlotterbeck (*Proc. A. Ph. A.*, 1901, p. 247), who finds that the plant contains *berberine*, besides an alkaloid, *protopine* (*argemone* of Peckoldt). The seeds of the plant have been used in *colic*, 8 grains (0.5 Gm.), given in emulsion, and repeated if necessary every half hour until three doses have been taken. (*P. J.*, xiii. 642.)

Argentamin.—Argentamin is a solution of silver phosphate in ethylene diamine. It is a clear, strongly alkaline liquid, sp. gr. 0.97, which does not precipitate albumin. It is said to contain 10 per cent. of the silver salt. Its use in medicine was proposed in 1894 by Jean Schaeffer (*Zeitsch. f. Hyg. u. Infektions*, 1894, xvi. Bd. ii.). Hoor used it in a large number of eye cases; he asserts that it causes less pain and irritation than the silver nitrate, and penetrates deeper. He used a 5 per cent. solution in the eye from one to four times a day in the same cases as those in which silver nitrate is useful. According to Aschner (*Orr. hetil.*, 1895), it is well borne by the posterior urethra in a strong solution, as 1 to 250; but the anterior urethra will not bear more than 1 to 2000.

Argonin. Argentum Casein.—This is a white powder, of neutral reaction, prepared by mixing a solution of a sodium compound of casein with silver nitrate and precipitating with alcohol. It is readily soluble in warm or albuminous water, with difficulty in cold water. A 10 per cent. solution in warm water is said to be permanent in the dark. (*A. Leibrecht, Th. M.*, vii. 1895.) Fifteen grains (1 Gm.) of this substance contain as much silver as does one grain (0.065 Gm.) of the silver nitrate. It makes a neutral solution in water, and has been very highly recommended by both German and American clinicians in the treatment of acute and chronic cases of *gonorrhœa*. Its 10 per cent. solution causes no pain in acute *gonorrhœa*. According, however, to the elaborate study of H. M. Christian, it is not of much service in the treatment of *posterior urethritis*. One hundred and sixty minims (10 Cc.) of a 2½ to 3 per cent. solution may in the acute stages of the disease be injected into the urethra and allowed to remain there for five minutes. A solution—0.3 ammonia water, 0.6 argonin, 100 of water—is said by R. Mayer to be much more powerful than argonin itself.

Argyrol.—A proteid salt of silver, *silver vitelin*, in the form of black, hygroscopic scales representing about 30 per cent. of metallic silver. The aqueous solution, it being soluble in all proportions in water, is not readily decomposed and will not precipitate chlorides or coagulate albumin. Alkalies do not precipitate it from solution, but it is precipitated by zinc sulphate, lead acetate, fluid hydrastis and acids. It is used locally, in solutions as strong as 50 per cent., without irritation.

Arheol.—Arheol is an alcohol of the formula $C_{15}H_{26}O$, obtained from oil of sandal wood and constituting from 60 to 90 per cent. of the latter. It is an oily liquid, and is marketed in three grain (0.2 Gm.) capsules, six to twelve of which are given per day. It is affirmed to have the same remedial action as oil of sandal wood, but to be free from the tendency to cause gastric disturbance. *Dose*, 5 to 10 minims (0.3–0.6 Cc.).

Aristochin. Aristokin. Aristokinine. Di-quinine carbonic ether. ($C_{20}H_{23}N_2O$) $_2$ CO $_3$.—A white or pinkish-white amorphous powder, soluble in alcohol, ether, chloroform, glycerin, and dilute acids, but insoluble in water. It is said to contain 96 per cent. of quinine, and probably is an effective antiperiodic, but has been chiefly used in *whooping cough*, given in doses of 1 to 5 grains (0.065–0.32 Gm.), three times a day.

Aristolochia. Br. Add.—There are several species of the genus *Aristolochia* which are found in the herbalists' stores of India but do not enter commerce. Of these *A. bracteata*, Retz, is employed as an emmenagogue. *Aristolochia* of the Br. Add. is the dried stem and root of *Aristolochia indica*, L. As sold in commerce this drug consists chiefly of stems with attached roots and is employed for the cure of snake bite and to produce abortion. The possession by it of any distinct medicinal properties is very doubtful. The Br. Add. recognizes the *concentrated liquor* (1 in 2 of 20 per cent. alcohol) (*Liquor Aristolochie Concentratus*, Br. Add.), *dose*, one-half to two fluidrachms (1.8–7.5 Cc.); the *tincture* (1 in 5 of 70 per cent. alcohol) (*Tinctura Aristolochie*, Br. Add.), *dose*, one-half to one fluidrachm (1.8–3.75 Cc.).

Armeria. Armeria vulgaris, Willd. (*Statice Armeria*, L.) *Maiden Pink*. (Fam. Plumbaginaceæ).—This plant, found in Europe, Asia, and Western North America, is said to be an active diuretic. (*Ph. Post*, May, 1890.)

Aromatic Wine. Vinum Aromaticum. Vin aromatique, Fr. *Aromatischwine*, G.—“Lavender, one part [or seventy-two grains]; Origanum, one part [or seventy-two grains]; Peppermint, one part [or seventy-two grains]; Rosemary, one part [or seventy-two grains]; Sage, one part [or seventy-two grains]; Wormwood, one part [or seventy-two grains]; Stronger White Wine, a sufficient quantity, to make one hundred parts [or one pint]. Mix the solid ingredients, and reduce them to a coarse (No. 20) powder. Moisten the powder with four parts [or six fluidrachms] of Stronger White Wine, pack it moderately in a conical glass percolator, and gradually pour enough Stronger White Wine upon it to make the filtered liquid weigh one hundred parts [or measure one pint].” *U. S.* 1880.

This preparation of the U. S. Pharmacopœia of 1880 is practically identical with the *Vin aromatique* of the French Codex, which is made by macerating one hundred parts of aromatic species (a mixture of equal parts of the herbs used in our official aromatic wine, and in addition wild thyme and hyssop) with one hundred parts of *Teinture vulnéraire* (a tincture containing the same herbs, and ten more of similar properties) and one thousand parts of red wine. This wine is principally used as an astringent and stimulating lotion to *chancres*, *open buboes*, and other *indolent ulcers*. In many cases it should be diluted, but on occasion it may be employed of full strength. It is never given internally, and is rarely used in this country.

Arrow Poisons.—Up to the seventh century poisoned arrows were used in Europe in warfare, and they seem not to have disappeared from Spain until the sixteenth century, while poisoned daggers and poisoned swords were used even later for assassinations. The nature of the poisons employed is obscure, though it is stated that *Vera-trium album*, L., and snake venom were used. The peregrinations of English and American travellers in Africa, and the various political changes and fomentations which have been the fruit of their discoveries,—the war with Spain and the consequent bringing of attention to the Philippine Islands,—have developed so much general interest in the wild natives of these various remote regions that we have thought it proper to prepare for our readers a general summary of what is known in regard to the poisons used by these various natives for the killing of game and the destruction of their enemies. In doing this we have thought that a geographical arrangement might well suffice. We shall omit strophanthus and the wooraris, which have become commercial products.

So far as our knowledge goes no poisonous arrows have ever been used in North America or in Northern Asia, unless, indeed, the statements made by Kracheninikow be correct. In the second volume of his *Voyage en Sibérie*, French edition, 1768, this traveller states that the roots of the plant known as *Zgate* are employed by several tribes living in the far north of Asia as an arrow poison, and it has been suggested, probably with insufficient reason, that the plant is an anemone. We have met with no recent author who has seen this poison.

Of the *Asiatic arrow poisons* the most important are those which have long been used by the natives of Java and other East India islands under the names of *Upas antiar* and *Upas tieute*. The *Upas antiar* is a gum-resinous exudation obtained from the *Antiaris toxicaria*, Lesch., a large tree belonging to the Artocarpaceæ, growing in Java, Celebes, and the neighboring islands. Like certain species of *Rhus*, this plant exhales an æriform matter which very unpleasantly affects some of those who approach it, causing eruptions upon the skin attended with much swelling; hence the fable of the *deadly upas tree*. The juice is mixed with various substances to give it due consistency. Whether taken internally or introduced into the system through a wound, upas acts with extreme violence, producing vomiting, great prostration, a feeble, irregular pulse, involuntary evacuations, and convulsive movements, which are soon followed by death. Pelletier and Caventou obtained from it a glucoside, *antiarin*, crystallizable, soluble in water and alcohol, but scarcely so in ether, and of the formula $C_{14}H_{20}O_5$. *Upas antiar* depends for its activity upon *antiarin*, the crude drug and its active principles causing similar symptoms. *Antiarin* is a muscle poison, producing first strong fibrillary contractions of the voluntary muscles, followed by rapid decrease in irritability and finally paralysis, the sarcolemma of the muscles and not the motor nerve endings being the part attacked. It also belongs to the digitalis group of cardiac stimulants, raising the blood pressure at first, but finally arresting the heart in systole and being capable of re-establishing rhythmic contractions in the heart paralyzed by hydrocyanic acid. It appears to be the most active of known cardiac poisons. According to Stockman, *antiarin* diminishes the irritability of the peripheral vagi and

stimulates the vasomotor centres. The relative powers of *strophanthin*, *urechitin*, and *antiarin* are such that $\frac{1}{1000}$ gr. *strophanthin*, $\frac{1}{1000}$ gr. *urechitin*, $\frac{1}{1000}$ gr. *antiarin* are equivalents. (See Maurice Doyen, *A. de P.*, 1892; Kiliani, *P. J.*, lvii.; Headborn, *A. E. P. P.*, xlv.; W. Straub, *A. E. P. P.*, xlv. 1901.) H. W. Bettink claims (*Ned. Tijdschr. v. Pharm.*) that besides *antiarin* there are present in *Upas antiar* two other active principles, *cepain* and *toxicarine*. Headborn states that *antiarigenin*, a derivative of *antiarin*, is more powerful than *antiarin* itself.

The *Upas tieute* is said to be obtained from a climbing woody plant growing exclusively in Java, the *Strychnos Tieute* of Leschenault. This author states that a decoction of the bark of the root is concentrated to the consistence of a thin syrup, then mixed with onions, garlic, pepper, etc., and allowed to stand until it becomes clear. This poison produces death in violent convulsions, and strychnine is said to have been found in it. (*Am. J. M. S.*, 1860; *C. D.*, 1863.)

It is very probable that different extracts are employed by different tribes in the islands of the Malay Archipelago. Braidwood (*Ed. M. J.*, 1864) found the arrow poison known as *Dajaksh* to be a cardiac paralyzant. It is not clear whether this is the same as a Borneo arrow poison examined by Leubuscher. (*Cb. I. M.*, Bd. xvii. 1896.) This is a blackish-brown, structureless extract, with yellowish streaks through it; it is believed by Leubuscher to contain an alkaloid which he failed to isolate. This poison produced in the lower animals great muscular relaxation, with convulsive movements and direct cardiac arrest in systole, but had no direct effect on the respiration, the peripheral nerves, or the muscles. In the higher animals the blood pressure was reduced even by minute doses.

The arrow poisons used by the natives of the Philippine Islands are, according to the researches of P. C. Plugge (*A. J. P.*, ii. 1896), obtained from the *Rabelaisia philippinensis*. Plugge has found in it a non-nitrogenous glucoside, *rabelaisin*. This given in very large doses produced in animals some convulsive movements, followed by profound muscular relaxation, loss of reflexes, and general paralysis, ending in death from asphyxia. On the heart it acted as an energetic stimulant, belonging to the digitalin group. In the frog one-ninth grain (0.007 Gm.) produced great cardiac excitement. (See also I. Rosenthal, *Sitzungsber. f. Physik. u. Med. Soc.*, Erlangen, 1894.)

An arrow poison is used by the Malays, under the name of *Iphoh*; it is said to be obtained from *Derris* (*Pterocarpus elliptica* (Fam. Leguminosæ), or the *tuba root*, which is much used in Java as a fish poison. It contains an active acid resin, to which the name of *derrid* has been given. *Derrid* appears to be one of the most powerful fish poisons known, as one-five-millionth part stupefied gold fish in a few moments, and killed them within half an hour. (*P. J.*, vol. xxi. 1890.) Later researches seem to throw doubt upon the distinctness of *iphoh* poison from *Upas antiar*. (See *P. J.*, 1892.)

The natives of Perak, in the Straits Settlements, use an arrow poison stated to be a combination of aqueous extracts from the root bark of three trees, the individual extracts being known as *iphoh alker*, *aker lampong*, and *prual*. *Iphoh alker* and *aker lampong* are believed to be obtained from undescribed species of *Strychnos*; extracts were prepared from the root bark of these trees by Ralph

Stockman (*Lab. Rep. Roy. Soc. Edinburgh*, vol. vi. 1897), and found to be of similar physiological power, each of them having a digitalis-like action and also a well marked curare-like action, causing arrest of the heart in systole and loss of power in the motor nerve endings. *Pruai* is said to be made from the root bark of *Coptosapella flavescens* (Fam. Apocynaceæ); in the experiments of Stockman it was found to be a violent poison, very rapidly killing the muscle at the point of inoculation, and soon involving in a fatal influence the whole muscular system, so that the animal after a large dose collapsed almost at once with diastolic cardiac arrest.

The African arrow poisons are quite numerous. *Eauja* or *Echugin* is a blackish-brown, crumbly, odorless, and intensely bitter arrow poison, used by the Ovambos of Southwest Africa. It is said to be yielded by an apocynaceous shrub, *Idaneum* (*Adenium*) *boehmianum*. From it R. Böhm (Cb. M. W., 1889) isolated the crystalline glucoside ($C_5H_9O_2$), *echugin*, and a resinous body, *echugon*. The glucoside crystallizes in small, colorless, satiny, rhombic plates, easily soluble in water and alcohol, and insoluble in ether. It is present to about 10 per cent. in the crude substance, and is said to very closely resemble strophanthin in its physiological properties.

The arrow poison used by the pygmies of Central Africa has been obtained by Surgeon Parke, and is described in the *P. J.*, April, 1891. It has been found to contain two active alkaloids, *erythrophloxine* and *strychnine*.

The Sakayes, the Somangs, and the Wa Kamba tribes in Eastern Africa produce arrow poisons whose relations with one another are still obscure. *Hippo*, according to Laborde, causes in the lower animals vomiting, followed by tetanic convulsions and an almost simultaneous arrest of the respiration and cardiac action. (*P. J.*, July, 1887.) *Vakamba* of Laborde (*Ibid.*) is probably the same as the *ukambin* which has been studied by H. Paschki, who found its active principle to be a crystalline body belonging to the digitalis group, and causing in the lower animals elevated blood pressure, fibrillary contractions of the muscles, and systolic arrest of the heart. (Cb. M. W., 1862.)

An exceedingly bitter arrow poison, used by the tribes who inhabit the country of Segon in the French Soudan, has been examined by Ferré and Busquet (*A. de P.*, vii. 1895), who find that its active principle is a crystalline glucoside which is a very powerful muscle poison, affecting directly the heart, and producing very rapidly general paralysis, with salivation, exophthalmia, disturbance of respiration and of circulation. The first influence is to increase greatly the arterial pressure. The whole action of the poison is very similar to that of strophanthin.

The botanical sources of the rare African arrow poisons just mentioned are unknown, and it is uncertain whether these poisons are or are not distinct from better known African poisons. It is certain that several species of the apocynaceous genus *Acocanthera* afford several arrow poisons to the natives of Africa. Of the four principal species, *A. Schimper*, B. and H., is found abundantly in the highlands of Abyssinia and through a great portion of Eastern Africa; *A. deflersii*, Schwf., which resembles the last-named species closely but, according to Schweinfurth, differs in that its flowers are larger, sweet-smelling and pure white, has been found in the neighborhood of

Yemen; *A. Ouabaio*, Arnaud, is a native of Somaliland, and *A. venenata*, Don, of South Africa. For details, see Engler, *Botanische Jahrbücher*, Bd. xvii.

The Wa Nyika, the Wa Gyriama, and the Wa Kamba tribes of Eastern Africa, and the natives of Obok on the Gulf of Aden, prepare vegetable arrow poisons probably from different species of plants, although the names *ouabain*, *wabayo*, and *ouabaio* seem to have been used as synonyms by missionaries and others sending the extract to Europe. Varigny and Langlois found that of *ouabaio*, coming from Obok, one-twelfth of a grain (0.006 Gm.) was sufficient to kill rabbits quickly, the heart and respiration being fatally poisoned. (*B. M. J.*, 1888.) One of these *ouabaio* extracts is certainly made from the root of *Acocanthera Schimper*, Benth. and Hook. (See *P. J.*, July, 1895.)

In 1882 Arnaud obtained from an unidentified species of the genus *Acocanthera* (which he named provisionally *A. Ouabaio*), a crystalline glucoside, and in 1893 Lewin separated from the *Acocanthera deflersii* an amorphous glucoside.

The French investigator, Arnaud, assigned to *ouabain* the formula $C_{30}H_{48}O_{12}$, and says that when injected into the stomach it is not poisonous, but when taken directly into the blood is most deadly, the one-sixty-fourth of a grain (0.001 Gm.) being sufficient to kill a man, and acting both upon the heart and the respiratory centres. Gley states that this *ouabain* is a local anæsthetic, having ten times the power of cocaine, and in this he has been largely corroborated by Sailer, Lewin, and others. (*C. R. S. B.*, ii. 1895.)

From the arrow poison of the Wa Kamba, von Brieger has separated a crystalline principle of extraordinary activity, assigning the formula $C_{29}H_{46}O_{19}$. It is a question whether this is or is not *ouabain*. The substance extracted by E. Baroni (*Annali di Medicina navale*, 1900) from the Somali poison appears to have been *ouabain*.

For the glucoside produced by the *Acocanthera Schimper*, Fraser proposes the name of *acocantherin*. In his experiments it crystallized from water in the form of colorless, transparent, quadrangular plates; from alcohol in needle-shaped crystals, often grouped in tufts and rosettes; had a melting point of about $186^{\circ} C.$ ($366.8^{\circ} F.$); was slowly soluble in water, more so in alcohol; and yielded to Dobbin the formula $C_{30}H_{48}O_{13}$. (See *P. J.*, lx. 1895.) Physiologically Fraser found this glucoside to act very much like strophanthin; it is a muscle poison, which affects directly the heart muscle and thereby causes rise of the arterial pressure. Its influence upon the blood vessels appears to be very much less than is that of digitalin. The fatal dose of *acocantherin* for frogs is 0.0000049 per gramme; for the rabbit, 0.00028 per kilogramme.

From *Acocanthera abyssinica* is prepared *Shashi-poison* of German Eastern Africa; from it E. S. Faust (*A. E. P. P.*, 48, 272, and 49, 446) separated a glucoside which he believes to be distinct from *acocantherin* in being amorphous and optically inactive.

The researches of Lewin in 1893 (*V. A. P. A.*, Bd. cxxiv.) strongly indicate that the glucosides of the North African species—that is, of *A. deflersii*, *A. Ouabaio*, and *A. Schimper*—are identical; but that the glucoside of *A. venenata* is diverse, it differing from the others chemically in not being precipitated by tannic acid, and in not producing with concentrated sulphuric

acid a typical green fluorescence. It was found by Lewin when injected hypodermically to act with great rapidity in the production of violent dyspnea and great weakness. It is from that species, *A. venenata*, Don, that the Bushmen of South Africa make an arrow poison by pounding the bark between stones, boiling it with water, then straining and boiling the water again until a jelly is formed, into which the point of the arrow is dipped. It is said that no snake poison is added; but it is further affirmed that under the name of *Incwadi* the Bushmen also use the bulbous amaryllidaceous plant, *Buphane disticha*, in poisoning their arrows.

Animal Poisons.—The use of animal arrow poisons is very uncommon, though the Choco Indians, in Colombia, South America, are said to prepare a very deadly extract by holding a tree-frog, the *Phyllobates chocensis*, on a stick near a fire, and scraping off the subsequent exudate from the skin. As it is asserted that an exudate can be obtained from the skin of the ordinary European toad which is a violent heart poison, the extract employed by the Choco Indians is probably a cardiac paralyzant. Again, according to Livingstone, confirmed by Baines, some of the Bushmen prepare a poison from a cream-colored grub or caterpillar, which they term 'Nga, said to be the first stage of the beetle *Diamphidia locusta*. The grub is gradually squeezed between the forefinger and thumb, and the colorless exudate smeared over the arrow-head. Boehm and his pupil Starcke have found this poison to be similar in its action to the snake poisons, to be dependent for its activity upon a toxic albumose, and to be non-toxic when given by the mouth. As previously stated, it is also probable that snake venom is sometimes mixed with the various vegetable poisons used by barbarians.

Artabotrys. *Artabotrys odoratissimus*, R. Br. *A. hamatus*, Bl. *Uvaria sinensis* (Fam. Anonaciæ) and *Unona uncinata*, Blanco. *Ilag-ilag de China*, Sp.-Fil. *Ilag-ilag Sonson*, Tag.—A decoction of the leaves of this plant is used in the Philippine Islands in the treatment of *cholera*; the overdose is said to be capable of producing abortion.

Artar Root.—This is a drug coming from the west coast of Africa, possibly the product of *Xanthoxylum senegalense*, DC. (Fam. Rutaceæ), the leaves of which have been found in commercial specimens. Two alkaloids have been discovered in it by Giacosa and Nionari, one of which is said to resemble somewhat in its action veratrine, and to be a stimulant to the heart. (*Ph. Centralh.*, No. xxv. 1887.)

Artemisia Frigida, Willd. *Sierra Salvia*. *Colorado Mountain Sage*. (Fam. Compositæ.) This Rocky Mountain plant, which is found growing in immense quantities in Western America, is said to be much used in that region as a diaphoretic, antiperiodic, and mild cathartic. F. A. Weiss (*A. J. P.*, 1890) found indications of a glucoside. The dose of cold infusion (2 oz. in pint) is a wineglassful three times a day. One or two drachms (3.9 or 7.7 Gm.) of the powdered leaves, or one or two fluidrachms (3.75 or 7.5 Gm.) of the fluidextract, may be administered in hot infusion every half hour until perspiration has set in.

Arum.—The root or corm of *Arum maculatum*, L., is occasionally used as a medicine in Europe. Its properties closely resemble those of *Arisæma triphyllum*. Its constituents, according to Enz, are a neutral acrid volatile principle soluble in ether, starch, gum, mucilage, sugar, lignin, albumen, saponin, fixed oil, resin, and

phosphate of calcium, the fresh corm containing 58.4 per cent. of water, 5.2 of lignin, and 27.2 of starch. (*A. J. P.*, xxxi.)

Arisæma triphyllum (L.), Torr. *Arum triphyllum* (L.). *Gouet à trois feuilles*, Fr. *Dreiblattiger Aron*, G. (Fam. Araceæ.) *Dragon-root*, *Indian Turnip*, *Jack-in-the-pulpit*, or *Wake-robin*. This plant is a native of North and South America, and is common in all parts of the United States, growing in moist shady places. The corm was formerly official. It is roundish, flattened, an inch or two in diameter, covered with a brown, loose, wrinkled epidermis, and internally white, fleshy, and solid. In the recent state it has a peculiar odor, and is violently acrid. It was found by D. S. Jones, besides the acrid principle and from 10 to 17 per cent. of starch, to contain albumen, gum, sugar, extractive, lignin, and salts of potassium and calcium. (*A. J. P.*, xv. 83.) The acridity has been ascribed to the raphides of calcium oxalate by R. A. Weber (*J. Am. C. S.*, 1891, p. 215). This has been denied, Schneegans proving that *A. maculatum* contains saponin and Spica and Biscaro ascribe the acridity to saponin (*Ph. Centralh.*, 1895, p. 731). The Indian turnip may be preserved fresh for a year, if buried in sand.

From both *Arum maculatum* and *Arum italicum*, Herbert and Heim (*P. J.*, July 31, 1897) separated a saponin, also a brownish, oily, liquid alkaloid closely resembling conine in its properties, but less active. They also found a saponin in the arum tubers.

Both the European and American arum are, in their fresh state, violent irritants to the mucous membranes, producing when chewed insupportable burning in the mouth and throat. Taken internally, this plant causes violent gastro-enteritis, which may end in death. (See *Ann. Thér.*, 1862.) The fresh, partially dried root has been used internally as a stimulant to the secretions, especially in *asthma*, *whooping cough*, *chronic catarrh*, and *rheumatism*. Dose, ten grains (0.65 Gm.), two or three times a day, increased to half a drachm (2 Gm.). The perfectly fresh root should not be used, and the fully dried root is inactive.

The corm of the European arum contains much starch, and a farina is prepared from it, in small quantities, in the Isle of Portland, on the south coast of England, and called *Portland arrow root*, or *Portland sago*. The root of *A. esculentum*, L. (more correctly *Colocasia esculenta* (L.), Schott.), which abounds in starch, is much used by the natives of the Hawaiian and other islands of the Pacific as an article of food, having been previously deprived of its acrimony by heat.

Asarabacca.—*Asarum europæum*, L., is an acrid, herbaceous perennial plant, of the Fam. Aristolochiaceæ, growing in Europe, between 37° and 60° north latitude, in woods and shady places. The root is about as thick as a goose-quill, of a grayish color, quadrangular, knotted and twisted, and sometimes furnished with radicles at each joint. It has an odor analogous to that of pepper, an acrid taste, and affords a grayish powder. The leaves, which have long footstalks, are kidney-shaped, entire, somewhat hairy, of a shining deep green color when fresh, nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. According to Feneulle and Lassaigue, the root contains a concrete volatile oil, a very acrid fixed oil, a yellow substance analogous to *cystin*, starch, albumen, mucilage, citric acid, and

saline matters. Gräger found in the root a liquid volatile oil, two concrete volatile substances called respectively *asarum-camphor* or *asaron*, and *asarite*, a peculiar bitter principle called *asarin*, tannin, extractive, resin, starch, gluten, albumen, lignin, citric acid, and various salts; in the *leaves* asarin, tannin, extractive, chlorophyll, albumen, citric acid, and lignin. Rizza and Butlerow give to *asaron* the formula $C_{12}H_{16}O_8$, and state that it melts at $59^{\circ} C.$ ($138.2^{\circ} F.$), boils at $296^{\circ} C.$ ($564.8^{\circ} F.$), has the sp. gr. 1.165 at $18^{\circ} C.$ ($64.4^{\circ} F.$), is inodorous, has a faintly pungent taste, is somewhat soluble in boiling water, and crystallizes on cooling in delicate needles and scales. Gräger's *asarite* is merely asaron crystallized in fine needles. (*Ber. d. Chem. Ges.*, 1884, 1159.) Poleck (*Ibid.*, 1415) gives the fusing point of asaron as $61^{\circ} C.$ ($141.8^{\circ} F.$), and its formula as $C_8H_{10}O_2$. The active principles appear to be the volatile oil, which is lighter than water, glutinous, yellow, of an acrid and burning taste, and an odor like that of valerian, and the *asarin*, which is soluble in alcohol and very bitter, and is probably the same as the *oystin* of Feneulle and Lassaigne. (See *Cytisus*.) The volatile oil of the plant has been examined by Petersen: it consists of an oil which has the composition $C_{11}H_{14}O_2$, and is identical with the *methyl ether of eugenol*, and a terpene, $C_{10}H_{18}$, boiling between $162^{\circ} C.$ ($323.6^{\circ} F.$) and $165^{\circ} C.$ ($329^{\circ} F.$). (*A. Pharm.*, 1888-89, 123.) The root and leaves of *asarabacca* are powerfully emetic and cathartic, in doses of from thirty grains to a drachm (2.0-3.9 Gm.), but are used almost exclusively as an emetine in headache, and rheumatic affections of the face, mouth, and throat. One or two grains (0.065-0.13 Gm.), snuffed up the nostrils, produce much irritation, and a copious, persistent flow of mucus.

Asarum. *Wild Ginger*, or *Canada Snake-root*. *Asaret du Canada*, Fr. *Canadische Haselwurzel*, G.—Under this name the U. S. Pharmacopœia formerly recognized the rhizome of the indigenous *A. canadense*, L. (Fam. Aristolochiaceæ.) The plant has in all its parts an aromatic odor and an aromatic slightly bitter taste, which it imparts to alcohol and hot water. The rhizome occurs in long, more or less contorted pieces, from the thickness of a straw to that of a goose-quill, brownish and wrinkled externally, whitish within, hard and brittle, and frequently furnished with short fibres. The chief constituent is the volatile oil, now largely used in perfumery. According to Petersen, the oils of *Asarum europæum* and *Asarum canadense* are composed in the main of one compound, which is identical with the *methyl ether of eugenol*, $C_8H_5(OCH_3)_2.C_3H_5$, a compound which had been made synthetically but not previously found in nature. According to the latest researches of Power and Lees (*Trans. Chem. Soc.*, 1902) the oil of *Asarum canadense* contains the following substances: a phenol, $C_8H_{10}O_2$; pinene, apparently a mixture of the d- and l- forms; d-linalool, l-borneol, l-terpineol, geraniol, eugenol-methyl-ether, a blue oil, of undetermined composition, consisting of oxygenated substances of alcoholic nature; a lactone, $C_{14}H_{20}O_2$, palmitic acid, acetic acid, and a mixture of fatty acids intermediate between acetic and palmitic acids. For formulas for fluidextract, syrup, and oleo-resin, see *A. J. P.*, 1876, 155. F. P. Streepier (*A. J. P.*, 1888, 6) proved that strong alcohol was the proper menstruum for the fluidextract. The medicinal properties of this drug are those of a feeble aromatic. From a half to one drachm (2-3.9

Gm.) may be used. It is employed as an aromatic adjuvant to tonic mixtures and infusions. From *Asarum arifolium*, Michx., E. R. Miller obtained from 7 to 10 per cent. of volatile oil having a sassafras odor, sp. gr. 1.0585 (*P. J.*, lxi.); see also *Schim. Rep.*, 1902, p. 12.

Asbestos.—This term is applied to several mineral substances which occur in long capillary crystals placed side by side, the whole producing a fibrous mass which possesses qualities that render asbestos very valuable in the arts. Asbestos is incombustible, insoluble, and a poor conductor of heat. It is usually hydrated *magnesium silicate*, or a compound of silicon, lime, and magnesium (for analysis see *P. J.*, 1901, p. 575), and is found in Italy, in the Tyrol, Corsica, Savoy, in the Pyrenees, in Cornwall, Scotland, and elsewhere in Europe. It is largely mined in Canada and the United States, the production of the latter, in 1904, having been 1,480 tons, valued at \$25,740. For its general properties and uses, see *Ph. Rec.*, 1885, 232. In the laboratory it is used for filters, for which it is admirably adapted. (See *Talcum*, page 1238; and *A. J. P.*, 1883, 37; *Ph. Rund.*, 1885, 252.)

Asbolin.—Under this name Braconnot has introduced a brownish-yellow syrupy liquid, prepared from an aqueous infusion of lamp black. Béhal and Desvignes state that it consists mainly of pyrocatechin and homopyrocatechin. It has been used in the treatment of tuberculosis.

Asclepias. U. S. 1890.—Besides the American species *Asclepias tuberosa*, *A. syriaca*, and *A. incarnata*, which were formerly recognized by the U. S. Pharmacopœia, various other species of the genus have been used medicinally. Gram has found in the *Asclepias Curassavica*, *A. incarnata*, *A. Vincetoxicum*, and *A. officinale*, a glucoside, *asclepiadin*, which he believes to be a pure form of the asclepiadin of Harnack and the *asclepin* of Feneulle, and closely to resemble emetine in its physiological action, but to be so unstable as to be of no practical value. From *A. Vincetoxicum*, L. (*Cyananchem Vincetoxicum* (L.), Pers.), Tanret (*C. R. A. S.*, c. 277) has isolated two glucosides, soluble and insoluble *vincetoxin*, with the formula $C_{16}H_{12}O_6$. The soluble vincetoxin is a clear yellow amorphous powder, easily soluble in water, alcohol, and chloroform, insoluble in ether. It begins to decompose at $130^{\circ} C.$ ($266^{\circ} F.$). The insoluble vincetoxin dissolves readily in alcohol, chloroform, and ether, but in water only in the presence of the soluble vincetoxin. It fuses at $59^{\circ} C.$ ($138.2^{\circ} F.$). Decomposed by dilute acids, they each yield an uncrystallizable, inactive, unfermentable sugar. An indigenous species, *A. verticillata*, L., is used in the Southern States as a remedy in *snake bites* and the *bites of venomous insects*. Twelve fluidounces (360 Cc.) of a saturated decoction are said to cause an anodyne and sudorific effect, followed by a gentle sleep. (*Va. Med. Journ.*, Dec. 1858.)

A. syriaca, Willd. *A. Cornuti*, Decaisne.—*Common silk weed*, or *common milk weed*, is very abundant in the Middle United States, flowering in July and August. Its milky juice has a faint odor, a sub-acrid taste, and an acid reaction. According to Schultz, 80 parts of it contain 69 of water, 3.5 of a wax-like fatty matter, 5 of caoutchouc, 0.5 of gum, 1 of sugar, with salts of acetic acid, and 1 of other salts. (*Ph. Cb.*, 1844, p. 302.) C. List found the chief solid ingredient of the juice to be a peculiar resinous crystalline substance (*asclepin*,

$C_{26}H_{34}O_3$) allied to lactucon. To obtain it, the juice is coagulated by heat, filtered, and the filtrate digested with ether, which dissolves the asclepien, and yields it by evaporation. To purify it, the residue must be treated repeatedly with anhydrous ether, which leaves another substance undissolved. It is white, crystalline, tasteless, inodorous, fusible, insoluble in water and alcohol, soluble in ether, oil of turpentine, and concentrated acetic acid. A hot solution of potassium hydroxide does not affect it. (*Ann. Ch. Ph.*, Jan. 1849. See also *A. J. P.*, liii.) Anodyne, cathartic, and alterative properties have been claimed for the root of this plant, and it has been especially commended in *asthma* and in *scrofula*, but probably is of very little medicinal value. A fluidrachm (3.75 Cc.) of it in decoction may be given two or three times a day.

Asclepias tuberosa, L.—*Butterfly weed*, or *pleurisy root*, grows throughout the Eastern United States, most abundantly southward. The roots, which alone are used in medicine, were officially described as "large and fusiform, dried in longitudinal or transverse sections, from 2 to 15 Cm. long, and about 2 Cm. or more in thickness; the head knotty, and slightly but distinctly annulate, the remainder longitudinally wrinkled, externally orange-brown, internally whitish; tough, and having an uneven fracture; bark thin, and in two distinct layers, the inner one whitish; wood yellowish, with large, white, medullary rays. It is inodorous, and has a bitterish, somewhat acrid taste. When long kept it acquires a gray color." *U. S.* 1890.

When dried, it is easily pulverized, and its taste is bitter, but not otherwise unpleasant. E. Rhoads discovered in it a peculiar principle, which he obtained by treating the cold infusion with tannic acid, mixing the precipitate, previously washed and expressed, with litharge, drying the mixture and exhausting it with hot alcohol, and finally decolorizing and evaporating the alcoholic liquor. The product was a yellowish-white powder, having the taste of the root, soluble in ether, and much less readily so in water, from which it was precipitated by tannic acid. Rhoads also found evidence of the existence in the root of tannic and gallic acids, albumen, pectin, gum, starch, a resin soluble and another insoluble in ether, fixed oil, a volatile odorous fatty matter, and various salts, besides from 30 to 35 per cent. of lignin. (*A. J. P.*, xxxiii.) Quackenbush (*A. J. P.*, 1889) found in it and also in *A. Cornuti* a crystalline glucoside.

To the root of the *A. tuberosa* have been ascribed diaphoretic, expectorant, and cathartic properties. In the Southern United States the drug has been given in *pulmonio catarrhs* in doses of from twenty grains to a drachm (1.3–3.9 Gm.) in a powder or in the form of a decoction; as a diaphoretic, a teaspoonful of the decoction (1 in 30) every hour until some effect is produced.

The formula for *fluidextract of asclepias official* in the *U. S. P.* 1890 is as follows: *Extractum Asclepiadis Fluidum*. *U. S.* 1890. *Fluid Extract of Asclepias*.—"Asclepias, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted

Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Asclepias is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.* 1890.

This fluidextract has a deep brownish-red color. The dose is from twenty minims to a fluidrachm (1.3–3.75 Cc.).

Asclepias Curassavica, L. *Bastard Ipecacuanha*. *Redhead*. *Blood Weed*. (Fam. Asclepiadaceæ.) This is a native of the West Indies, abounding especially in Nevis and St. Kitts. Both the root and expressed juice are emetic, the former in the dose of twenty to forty grains (1.3–2.6 Gm.), the latter in that of a fluidounce (30 Cc.) or more. They are also cathartic and vernifuge in somewhat smaller doses. (*A. J. P.*, xix. 19.) For analysis, see *A. J. P.*, 1887, 347. According to the *Kew Bulletin*, 1897, this plant has insecticidal properties, being especially obnoxious to fleas. The rooms are thoroughly swept with rough brooms made from the weed and the pests are said to disappear. D. St. Cyr commends it in *phthisis* (*P. J.*, 1903, 714).

Asimina. *Asimina triloba* (L.), Dunal. (Fam. Anonaceæ).—J. U. and C. G. Lloyd have found in the common pawpaw an alkaloid, *asiminine*, besides a volatile oil. (*A. J. P.*, 1886.) T. M. Fletcher failed to find an alkaloid, but gives the principal constituents as fixed oil, 3.53 per cent.; resin, 3.43 per cent.; resin insoluble in ether, 9.5 per cent.; glucose and extractive, 8 per cent. (*A. J. P.*, 1891, 476.)

Asparagus. *Asparagus officinalis*, L. *Asperge*, Fr. *Spargel*, G. *Esparaguera*, Sp. (Fam. Convalariaceæ).—This well-known garden vegetable is a native of Europe. It is perennial and herbaceous. The root, which is inodorous, and of a weak, sweetish taste, is used in France as a diuretic, aperient, and purifier, in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts that, in the dried state, it is wholly inert. In the *berries* H. Reinsch has found a large proportion of glucose and a yellowish-red coloring matter, *sparagin*. (*A. J. P.*, xlii. 371.) From the juice of the young shoots Robiquet and Vauquelin obtained a peculiar crystallizable principle, called *asparagin*, $C_4H_5N_2O_8$, which has since been found in a number of plants. (See *Althæa*.) Asparagin is said to be obtained with facility by the process of dialysis. If the thick viscid mucilage of the marshmallow (*Althæa officinalis*) be put into a dialyzer, with distilled water outside, the asparagin passes into the water, and may be obtained in crystals by evaporating the solution. (See *P. J.*, May, 1862, 572.) It might probably be obtained in the same way from an infusion of asparagus. The seeds are said to be used as a substitute for coffee. They are black in color, measuring about 4 millimeters in length and 3 in width, rounded on one side, squared on the other, with wrinkled seed capsule. W. W. Peters found in them a fixed, quickly drying oil of reddish-yellow color. Its sp. gr. at 15° C. (59° F.)

is 0.928, and the Zeiss refractometer at 25° C. (77° F.) shows 75° (1.75). The saponification figure is 194.1, the iodine figure after eighteen hours is 137.1. The acetyl-acid figure is 179.2, the acetyl-saponification figure 204.4, and the acetyl figure therefore 25.2. The oil in question was found to consist of the glycerides of palmitic, stearic, oleic, linoleic, linolenic, and isolinolenic acids. The average amount of water in the seeds was 11.52 per cent., the cellulose 8.25 per cent., the proteins 18.99 per cent. No starch was found, but 37.53 per cent. of mannose.

There is at present no sufficient reason for believing that asparagus is of value in practical medicine. The peculiar heavy odor which it imparts to the urine has been the chief foundation for the belief in its diuretic properties; but Nencki (*Provincial Med. Journ.*, March, 1891) appears to have demonstrated that this odor is due to the presence in the urine of *methyl-mercaptan*, a gas which is frequently produced in minute quantities in the intestines by the decomposition of proteids. A. Dedrick affirms that eight grains of asparagin caused marked reduction and irregularity of the pulse, frontal headache, and muscular weakness, lasting less than two hours. (*V. A. P. A.*, Bd. xciv. and xcvi.) According to Justin D. Lyle (*N. Y. M. J.*, July, 1892), eating asparagus causes the urine to answer Trommer's, Fehling's, and Böttger's glycosuria tests, although sugar is not present. The effect of asparagin upon tissue change has been studied by several physiologists, with somewhat diverse results. Weiske and his students are in accord with Zuntz in the conclusion that in herbivorous animals it reduces the destruction of albuminous material, while Munk, Politis, and Mauthner, experimenting upon dogs and rats, have reached the conclusion that asparagin has no influence, at least in carnivora, upon tissue change. (*Z. B.*, x. 1892.) Asparagus may be administered internally in the form of the syrup produced from the fresh juice or from the tincture.

Asphodelus. *Asphodelus bulbosus*. (Fam. Liliaceae.)—Under the name of *Tsinisse*, the corm of this plant is used in the East for mucilage and the adulteration of salep powder.

Aspidosperma. *U. S.* 1890. *Aspidosperma Quebracho Bark. Quebracho Blanco*. "The bark of *Aspidosperma Quebracho-blanco* Schlechtendal (nat. ord. *Apocynaceae*)."
U. S. 1890. *Quebracho* is an evergreen tree which sometimes reaches the height of one hundred feet, and is remarkable for its erect stem and its wide-spreading crown reaching out over the cacti and lower bushes among which it grows. The wood of the quebracho tree is not met with in commerce, but is said to be very hard, distinctly marked with rings of growth, and of a bright chocolate-brown color, except the very young wood, which is yellowish or reddish. According to Hesse and Penzoldt, the wood contains no alkaloids; it is used for tanning purposes in some parts of South America.

Quebracho bark is remarkable for the extreme thickness of the corky layer which often constitutes more than half of its entire substance, and is separated from the lower layer by a more or less sharply defined outline. The corky layer is usually externally dirty gray, or where it has been rubbed appears yellowish red. As seen with the magnifying glass it is traversed by nearly parallel yellowish lines having numerous whitish points

between them. The inner portion of the bark is uniform, except for whitish points. These characteristics of the bark are more plainly observed after moistening the surface. In different specimens the color of the inner bark varies up to light yellow. When examined with high powers the outer layer is seen to be composed of superimposed parenchymatous cells, traversed by bands of small, thick-walled cork cells, constituting the parallel lines before mentioned. The whitish points spoken of are groups of sclerenchymatous cells whose membrane has been so thickened by secondary deposits that the cavity is nearly obliterated. The inner portion of the bark is composed of parenchymatous cells, usually of a cinnamon brown color, rich in starch, and containing a light brown granular substance, with groups of sclerenchymatous cells similar to those already mentioned, but containing a dark yellow substance, which seems to be in drops. These sclerenchymatous cells are more abundant in the inner part of the bark, and are arranged in spindle-shaped fibres, which can be readily separated by scraping the inner surface of the bast. The fibres are surrounded by angular bodies, composed of numerous small cells, each containing a crystal of calcium oxalate. The *U. S. P.* 1890 description of *aspidosperma* is as follows: "In nearly flat pieces, about 1 to 3 Cm. thick; the outer surface yellowish-gray or brownish, deeply fissured; inner surface yellowish-brown or reddish-brown, distinctly striate; fracture displaying two sharply defined strata, of about equal thickness, and both marked with numerous whitish dots and striae arranged in tangential lines; the fracture of the outer, lighter colored layer rather coarsely granular, and that of the darker colored, inner layer short-splintery; inodorous; taste very bitter and slightly aromatic."
U. S., 1890.

In 1878, Fraude (*Ber. d. Chem. Ges.*, 1878, p. 2189; 1879, p. 1560) discovered in the quebrachoblanco an alkaloid, *aspidospermine*, $C_{22}H_{30}N_2O_2$; but a series of experiments have led F. Penzoldt to the conclusion that it does not represent the whole medicinal activity of the bark, and O. Hesse has found five other alkaloids, *aspidospermatine*, $C_{22}H_{28}N_2O_2$, and isomeric with it *aspidosamine*, $C_{22}H_{28}N_2O_2$, *quebrachine*, $C_{21}H_{26}N_2O_2$, and isomeric with this *hypoquebrachine*, $C_{21}H_{26}N_2O_2$, and *quebrachamine*. (*Ber. d. Chem. Ges.*, xiii. 2308.) *Aspidospermine* fuses at 205°–206° C. (401°–403° F.), is soluble in about 6000 parts of water at 15° C. (59° F.), the solution having a decidedly bitter taste, soluble in about 48 parts of absolute alcohol, in 106 parts of ether, insoluble in glycerin; it dissolves readily in fats and fixed oils, cod liver oil dissolving a larger proportion than it does of quinine. Its *sulphate* and *hydrochloride* are very soluble. The *citrate* is crystallizable, and very soluble. The yield of *aspidospermine* is small, 0.33 per cent. of the bark. *Aspidospermatine* is crystalline, and fuses at 162° C. (323.6° F.); *aspidosamine* is amorphous, and fuses at 100° C. (212° F.); *quebrachine* in colorless crystals fuses at 214°–216° C. (417.2°–420.8° F.); *hypoquebrachine* is a yellowish mass resembling albumin, and fuses at 80° C. (176° F.); *quebrachamine* forms colorless silky needles, only slightly soluble in alcohol, ether, chloroform, and benzoin, and fuses at 142° C. (287.6° F.). Two new sugars have also been extracted by Tanret, *quebrachite* and *lavograte inosite*. Tannin and starch have also been found in the bark.

The formula for the *fluidextract of aspidosperma*, official in the U. S. P. 1890, is as follows: *Extractum Aspidospermatis Fluidum*. U. S. 1890. *Fluid Extract of Aspidosperma*.—"Aspidosperma, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Glycerin, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol and three hundred cubic centimeters [or 10 fluidounces, 70 minims] of Water, and, having moistened the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of two hundred cubic centimeters [or 6 fluidounces, 366 minims] of Alcohol to one hundred cubic centimeters [or 3 fluidounces, 183 minims] of Water, until the Aspidosperma is exhausted. Reserve the first eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890.

This preparation, which has been largely used under the name of *fluidextract of quebracho*, now represents the drug. The dose is fifteen minims to a fluidrachm (0.9-3.75 Cc.).

Medicinal Properties and Uses.—Quebracho bark, originally suggested as an antiperiodic, has been frequently used as a remedy in cardiac and asthmatic dyspnea. Our knowledge of the physiological action of its various alkaloids is not sufficient for definite conclusions; it would even appear that some of its alkaloids are reported to be antagonistic to each other. As was first stated by Penzoldt, and subsequently proven by H. C. Wood, Jr., and Hoyt, the commercial aspidospermine produces a great increase both in the rate and depth of the respirations, this increase being followed by depression if the dose has been large enough to kill. The blood in the veins becomes of a bright red hue, a color which was attributed by Penzoldt to a loss of power in the corpuscles to yield up their oxygen. It has been shown, however, by Wood, Jr., and Hoyt, that its color is simply due to an excessive aeration of the blood produced by the violent breathing, the blood rapidly assuming a venous hue all over the body if the supply of air be mechanically interfered with. According to Wood and Hoyt, commercial aspidospermine produces a marked fall of the blood pressure, which appears to be due to a depressing action of the alkaloids upon the cardiac muscles.

Quebracho has been used to some extent in *emphysema*, *bronchitis*, *chronic pneumonia*, *uræmic dyspnea*, etc. The aspidospermine of commerce is a more or less impure mixture of all the alkaloids, and may be considered to represent the activity of the drug. Dose, from one-fourth to one-half a grain (0.016-0.032 Gm.). The fluidextract

may be given in doses of from fifteen minims to one fluidrachm (0.9-3.75 Cc.); the solid extract is said to be ten times the strength of the crude bark, and may be given in doses of from one to three grains (0.065-0.2 Gm.).

Aspirin. *Acetyl-salicylic Acid*. $C_6H_4 \begin{cases} OC_2H_3O \\ COOH \end{cases}$

It forms white crystalline needles, melting at 135° C., only slightly soluble in water; soluble in alkaline fluids with decomposition. Aspirin is probably decomposed by the alkaline juices of the intestines with the liberation of salicylic acid, which is then absorbed. The presence of salicylic acid in the urine can be recognized in twenty minutes to half an hour after the ingestion of the drug, but, according to Filippi and Bufalini, excretion takes place much more slowly than after sodium salicylate; so that it is probable that the intestinal decomposition of aspirin takes place slowly and that the drug exerts a more continuing influence upon the system than do the alkaline salicylates.

Aspirin is entirely capable of producing cinchonism and all the other disagreeable symptoms sometimes caused by the salicylates, but is certainly less prone to interfere with digestion than are the older preparations of the acid, and is a valuable, effective remedy in the subacute forms of *rheumatism*. The powder should not be given in capsules if there be any irritability of the stomach; but diffused in milk or in water. Dose, ten to fifteen grains (0.65-1.0 Gm.) three or four times a day.

Asplenium. *Asplenium Filix-femina* (L.), Bern. Female Fern. *Polypodium Filix-femina*, L. *Athyrium Filix-femina*, Roth.—The rhizome of the female fern has been supposed to possess similar vermifuge properties to that of the male fern. At present, however, it is not used. The vulgar name of female fern is also given to the *Pteris aquilina*, or common brake, which is further said by some authors to have the property of destroying the tape worm. The leaves of two species of Asplenium, *A. Trichomanes*, L., or common spleenwort, and *A. Adiantum-nigrum*, L., or black spleenwort, are mucilaginous, and have been used as substitutes for the maidenhairs (*Adiantum Capillus-venenis*, L., and *A. pedatum*, L.) as pectorals, though destitute of their aromatic flavor.

Aster. *Aster puniceus*, L. (Fam. Compositæ.) The aromatic astringent rootlets of this indigenous plant have been employed as a stimulating diaphoretic in rheumatic and catarrhal affections.

Asteracantha. *Asteracantha longifolia*, Nees. (Also known as *Hygrophila spinosa*, T. Anders.) *Ik Kirit*. (Fam. Acanthaceæ.)—This Indian plant is said by A. Jayesingha to be an energetic hydragogue diuretic. (Ph. Z. R., Sept. 1887.)

Asterol. *Mercury paraphenolsulphonate with ammonium tartrate*. $C_{12}H_{10}O_8S_2Hg.4C_4H_4O_6(NH_4)_2 + 8H_2O$.—A micro-crystalline reddish-white powder freely soluble in warm water. This substance was brought forward by Steinmann (B. K. W., 1899, No. 11, p. 229) as being almost as active as corrosive sublimate in its antiseptic powers without having local corrosive properties, and also not losing its bactericidal action in albuminous media. Vertun (B. K. W., 1899, No. 20), however, finds that these assertions are not warranted.

Atherosperma. *Atherosperma moschatum*, Labill. *Australian Sassafras*. (Fam. Monimiaceæ.) The bark of this tree, a native of Southern Australia, is said to have been long used by the aborig-

ines, and later by the settlers, in *rheumatism* and in secondary *syphilis*, and has been highly commended by Greeves (*L. L.*, 1862) in acute *bronchitis*. It has been stated that both the bark and the volatile oil are powerful poisons, and Zeyer (*Vierteljahrsschr. f. Pract. Pharm.*, x, 504) obtained from the drug an alkaloid, *atherspermine* ($C_{20}H_{20}NO_5$); see also Wittstein's *Organic Constituents of Plants*, 20. The abundant volatile oil is light yellow, and has a pleasant aromatic odor and taste, resembling those of oil of sassafras. Ralph Stockman (*Lab. Rep. Royal Coll. Phys.*, vi, 1897) found it to resemble in its physiological action oil of sassafras and other allied volatile oils. He took repeatedly ten minims (0.6 Cc.) without any pronounced effect, and one fluidrachm (3.75 Cc.) given to a rabbit caused only temporary stupor, with slowing of the respiration, but not of the pulse. Three fluidrachms (11.25 Cc.) caused in the rabbit marked depression of the heart and of the respiration, coma, and death in twelve hours by asphyxia.

Atoxyl. *Meta-arsenous-acid anilid*.—This is a white, odorless powder having a slightly saline taste, which is soluble up to 20 per cent. in hot water, 2 per cent. crystallizing out on cooling. If left standing the aqueous solution becomes of a yellowish color. Atoxyl contains 37.6 per cent. of metallic arsenic. According to F. Blumenthal, it is forty times less poisonous than is arsenic acid, although it contains about one-half as much metallic arsenic as does the acid. In sufficient doses Blumenthal found that it is capable of producing fatal gastric enteritis and hemorrhagic nephritis, and its physiological, toxic, and remedial properties are probably in direct proportion to its power of setting arsenic free in the system; so that there is no reason for supposing it superior to the older arsenical preparations, unless, as claimed by Schild, it is especially adapted for hypodermic use. Schild gives from three to fifteen minims (0.2–0.9 Cc.) of the twenty per cent. solution, hypodermically, for five days, subsequently on alternate days. He believes that it is a cardiac depressant, which is contra-indicated by weakness of the heart.

Azadirachta. *Neem. Margosa Bark, Br. Add. Azedarach, U. S. 1880. Pride of India. Pride of China. Ecorce d'Azedarach, Ecorce de Margousier, Fr. Zedrachrinde, G.*—While the U. S. P. formerly recognized the bark of the root, the Br. Add. directs the bark of the stem of *Melia Azadirachta*, L. (nat. ord. *Meliaceae*), a beautiful tree, thirty or forty feet high, with a trunk fifteen or twenty inches in diameter. This species of *Melia* is a native of Syria, Persia, and the north of India, and is widely cultivated. It is abundant in our Southern States. North of Virginia it does not flourish. "The bark [root] is in curved pieces or quills of variable size and thickness; outer surface red-brown, with irregular, blackish longitudinal ridges; inner surface whitish or brownish, longitudinally striate; fracture more or less fibrous; upon transverse section tangentially striate, with yellowish bast-fibres; inodorous, sweetish, afterwards bitter and nauseous. If collected from old roots, the bark should be freed from the thick, rust-brown, nearly tasteless, corky layer." *U. S. 1880.* The bark of the tree is "externally of a rusty-gray color, internally yellowish, and much foliated; coarsely fibrous; inodorous, bitter and slightly astringent; structure and thickness varying according to age." *Br. Add.* (For a description of the leaves and root

bark, see *Ph. Rev.*, 1896, p. 231.) Jacobs (*A. J. P.*, 1879, 444) believes that the active principle is a yellowish-white resin, and that the activity of the bark resides in the liber. Hanausek (1878) states that two kinds of oil of *azedarach* are used in Eastern Asia,—one from the fruit and the other from the seeds; the former is used medicinally, the latter only for burning. For characters of oil, see *P. J.*, Oct. 1888.

Azadirachta indica, A. Juss. (*Melia Azadirachta*, L.), or *Melia bark*, according to Broughton (*P. J.*, 1873, 992) contains a bitter amorphous resin, $C_{32}H_{50}O_{11}$, which fuses at 92° C. (197.6° F.), and a crystallizable principle, melting at 175° C. (347° F.). (See also *Ph. Rev.*, 1896, 231.) Cornish (*Ind. Ann. Med. Sci.*, 4, 104) had previously announced the presence of a bitter alkaloid, to which he gave the name *margosine*, from the Portuguese name for the tree, *margosa*.

The decoction of *azedarach* is affirmed to be cathartic and emetic, and in large doses narcotic; but in a number of experiments made by H. C. Wood with extracts from the dried bark and fruit, it was found impossible to poison frogs or rabbits. Robins eating of the sweetish fruit, of which they are very fond, are often rendered so far insensible as to be picked up under the tree; though they usually recover in a few hours. It has been suggested that sufficient alcohol is produced by the spontaneous fermentation of the berries to cause intoxication, but this is highly improbable. Children are said to eat the fruit without inconvenience, and possibly the robins simply choke themselves with the large berries. The bark is considered in the Southern States an efficient anthelmintic. The form of decoction is usually preferred. A quart of water is boiled with four ounces of the fresh bark to a pint, of which the dose for a child is a tablespoonful every two or three hours, until it affects the stomach or bowels. Another plan is to give a dose morning and evening for several successive days, and then to administer an active cathartic. The fresh bark and the fruit are said to be superior as vermifuges. The Br. Add. recognizes an *infusion* (*Infusum Azadirachtæ Indicæ*, Br. Add.), eighty-eight grains in a pint of cold water, dose, one-half to one fluidounce (15–30 Cc.); also a *tincture* (*Tinctura Azadirachtæ Indicæ*, Br. Add.), two ounces in a pint of 45 per cent. alcohol, dose, one-half to one fluidrachm (1.8–3.75 Cc.).

Azoles.—The chemical substances which were gathered together by Hantzsch under the name of azoles have been the subject of considerable physiological study. As, however, so far, these subjects, with the exception of antipyrine, have yielded no practical result, it is sufficient here to point out the article of Tappeiner (*A. E. P. P.*, xxvii, 1896), which contains references to the previous articles upon the subject.

Baccharis. *Baccharis cordifolia*, DC. *Mio Mio*.—This composite plant of Southeastern South America is notorious from its deadly effect upon sheep and cattle. Pedro N. Arata has isolated from it an alkaloid *baccharine*. (*P. J.*, x, 6.)

Bacillol.—This is an oily fluid of faint alkaline reaction, dark brown color, and specific gravity of 1.100, which forms clear solutions with water, and even when concentrated is only slightly irritating. It is asserted to be a preparation of cresol. Solutions of the strength of 0.5 per cent. markedly affect the action of pancreatin, while 0.2 per cent. prevent the growth of micro-organisms in agar

tubes. It is alleged that it does not attack instruments, is inexpensive compared with phenol, and relatively free from toxicity. According to Franz Werner, a 1½ per cent. solution kills the anthrax bacilli in from one to five minutes. (See W. K. R., vol. xv. p. 73, and Th. M., vol. xv. 1901.)

Bael Fruit. *Belæ Fructus*. Br. Add.—“The fresh halfripe fruit of *Ægle Marmelos*, Correa.” Br. Add. The so-called Bengal quince is a rather large aurantiaceous tree, growing in India, with an erect stem, few and irregular branches, an ash-colored bark, strong, very sharp, axillary thorns, single or in pairs, leaves and large white flowers, ternate. The fruit is a berry of delicious flavor, of about the size of a large orange, with a hard smooth shell, and from ten to fifteen cells containing besides the compressed, woolly seeds a large quantity of exceedingly tenacious mucilage, which when dried is hard and transparent. “Rind about one-eighth of an inch (3 Mm.) thick, firm, and covered with a nearly smooth pale brown or grayish firmly adherent epicarp. The pulp is juicy, becoming hard and brittle on drying and acquiring an orange-brown or cherry-red color externally; it has a faint aromatic odor, and its taste is mucilaginous, slightly acid, and faintly astringent.” Br. Add. The mucilage about the seeds is applied to various purposes in the arts, on account of its viscid properties. The rind is used in dyeing. The flowers are deemed refrigerant by the native physicians. The fresh leaves yield by expression a bitterish and somewhat pungent juice, which, diluted with water, is occasionally used in the early stage of catarrhal and other fevers. The bark of the stem and root is thought to possess febrifuge properties.

The dried fruit is imported into England in vertical slices, or in broken pieces consisting of a part of the rind with the adherent pulp and seeds. The rind is about one-eighth of an inch thick, covered with a smooth pale brown or grayish epidermis, and internally, as well as the dried pulp, pale brownish-orange, or cherry-red. When moistened the pulp becomes mucilaginous. The fruit is astringent to the taste, and yields its virtues to water by maceration or decoction. Pollock found in it tannic acid, a concrete essential oil, and a vegetable acid (M. T. G., Feb. 1864), but Flückiger states that the drug does not contain any appreciable quantity of tannin.

The difficulty of obtaining bael in England is said to have led to the substitution for it of *man-gosteen*, the fruit of *Garcinia Mangostana*, L. This is in irregular fragments of the rind, without adhering pulp. The pieces are convex, three or four lines or more in thickness, externally covered with a smooth, deep reddish-brown, easily separable coating, and internally pale reddish-brown or reddish-yellow, smooth, with projecting vertical lines. (P. J., May, 1867.)

Bael is employed in *diarrhœa*, *dysentery* with debility of the mucous membrane, and other diseases of the bowels with relaxation. The *dose*, two ounces of dried fruit in a pint of water boiled down to four fluidounces, is used in doses of one to two fluidounces (30–60 Cc.) every two to six hours; or the *Liquid Extract* of Bael,¹ Br. Add., may be given in doses of 1 to 2 fluidrachms (3.75–7.5 Cc.).

Balanites. *Balanites Roemerhii*. *Agialida*. (Fam. Zygophyllaceæ.)—The fruit of this plant is used medicinally in India. It contains a principle closely resembling *saponin*. The ripe seed yield about 50 per cent. of a fixed oil (*sachun oil*), which is used for burning. The unripe fruit is anthelmintic and purgative.

Balata. *Gum Chicla*. *Chicle*. *Tuno Gum*. *Leche de Popa*, Fr. *Zapota Gum*.—This is the dried milky juice of the *Bully Tree*, *Mimusops Kanki*, L. (*Mimusops Balata*, Crueg.; *Achras Balata*, Aub.; *Sapota Muelleri*, Blume), of the Fam. Sapotaceæ, a native of Northern South America from Mexico to Guiana. It is an oxidized hydrocarbon, both physically and chemically closely related to caoutchouc and gutta-percha, of a grayish-white color, with dark spots and veins; specific gravity 1.05; tasteless, but emitting an agreeable odor when warmed. It has the general properties of gutta-percha, differing, however, in being but slightly elastic, a property which specially fits it for the manufacture of transmission belts. Solid and somewhat crumbling at ordinary temperature, it softens at 49° C. (120.2° F.), and can be moulded like gutta-percha. It is used as a substitute for gutta-percha, but more especially in the manufacture of chewing gum, for which purpose it is imported in large amounts from Mexico. It is not used in medicine.

Balm of Gilead. *Balsam of Gilead*. *Mecca Balsam*. *Balsamum Meccæ v. Judiacum*. *Balsamum Gileadense*. *Baume de la Mecque*, Fr.—The genuine balm of Gilead is the resinous juice of *Commiphora Opobalsamum* (Forst.), Engl. (*Amyris gileadensis*, Linn., *Balsamodendron gileadense*, Kunth) (Fam. Burseraceæ), a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and is still esteemed by the Eastern nations as a medicine and cosmetic. In Western Europe and in this country it is seldom found in a state of purity, and its use has been entirely abandoned. It is described as a turbid, whitish, thick, gray, odorous liquid, becoming solid by exposure. It possesses no medicinal properties not existing in other balsamic or terebinthinate juices. It was formerly known as *opobalsamum*, while the dried twigs of the tree were called *cylobalsamum*, and the dried fruit, *carpobalsamum*.

Balsam of Cativo. *Cativo Balsam*.—This substance appeared in the London market in 1902 as a substitute for copaiba. It is a balsamic resin, opaque, of a dirty light brown color and slightly bitter taste, and having an extremely adhesive quality. According to Umney it is not soluble in 90 per cent. alcohol, but is soluble in ether and consists chiefly of acid resins with the addition of an oily substance. According to Weigel's analysis it consists of 80 per cent. of resin acids and 2 per cent. of volatile oil. It is said to be used by the natives as a drug, but more probably will be employed to manufacture fly paper and similar substances on account of its viscosity. It is supposed to be a product of *Prioria copaifera* (Fam. Leguminosæ). (See P. J., vol. lxix.; and Ph. Centralh., March, 1903.)

of the distilled water; pour off and reserve the clear liquor; repeat the maceration a second and third time for one hour, using for each maceration five pints (or five litres) of the distilled water; press the marc, and filter the mixed liquids through flannel. Evaporate to fifteen fluidounces (or 750 Cc.), and, when cold, add enough of the alcohol to produce one pint (or 1000 Cc.) of the liquid extract. Filter or otherwise clarify if necessary. Br. Add.

¹ Bael Fruit, bruised, 20 ounces (or 1000 grammes); Distilled Water, 15 pints (or 15 litres); Alcohol (90 per cent.), a sufficient quantity. Macerate the bruised bael fruit for twelve hours in five pints (or five litres)

Balsam of Cebur or Tagulaway.—Cebur or Tagulaway Balsam is prepared in the Philippine Islands by boiling the root and twigs of *Parameria vulneraria*, Radl. (Fam. Apocynaceæ), in coconut oil, so as to form a yellowish-white, oily liquid, which is used with asserted excellent results for skin diseases and wounds. (A. Pharm., Nov. 1885.)

Balsam of Lagam. *Lagam Balsam.*—A thick, yellowish, fluorescent liquid, of a peculiar aromatic odor, and bitterish, acrid taste, resembling copaiba. (A. J. P., 1883.)

Balsam of Riga. *Riga Balsam.* *Balsamum Carpathicum.* *Balsamum Libani.*—This is usually stated to be a product of *Pinus Cembra*, L. (Fam. Coniferae), a large tree growing in the mountainous regions and northern latitudes of Europe and Asia. The juice exudes from the extremities of the young twigs, and is collected in flasks suspended from them. It is a thin, white fluid, having an odor analogous to that of the juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Cronstadt in bottles. Keller of Darmstadt, affirms that Riga Balsam is nothing but the product of the ordinary *Pinus palustris*, Mill. A similar product, called *Hungarian balsam*, is obtained in the same manner from *Pinus Pumilio*, Haenke, growing on the mountains of Switzerland, Austria, and Hungary. The oil derived from the young branches of the *Pinus Pumilio* (*Oleum pini pumilionis*, *Oleum templinum*, *Krummholzzöl*, *Pumiline*) is the most potent agent in the so-called *pine-cure* in the German spas. Schimmel & Co. (Schim. Rep., April, 1897) find it to contain *lævo-pinene*, *lævo-phellandrene*, and other terpenes, and from 4 to 7 per cent. of *bornyl acetate*, boiling above 185° C. (365° F.). When pure, it is said to be a very fragrant volatile oil, especially adapted for the purposes of inhalation. Internally it may be given in doses of from five to ten minims (0.3–0.6 Cc.), in capsules, as a stimulant expectorant.

Balsam of St. Thome. *Pan Olæo*, *Belam Pu*. A balsam obtained from *Santiriopsis balsamifera* (Fam. Burseraceæ). It is a resinous juice obtained by incisions in the trunk of the tree. It is used as a vulnerary and in diseases of the bladder and respiratory organs. (Ap. Ztg., 1898.)

Balsam of Sulphur. *Oleum lini sulfuratum.* *Oleum Sulphuratum.*—The old Edinburgh Pharmacopœia directed to boil eight parts of olive oil and one part of sublimed sulphur together, over a gentle fire, in a large iron pot, stirring them constantly until they united. As the vapors which rose were apt to take fire, a lid was to be at hand to cover the pot, and thus extinguish the flame if necessary. In this way the oil was partly decomposed, and the resulting preparation was an extremely fetid, acrid, viscid, reddish-brown fluid, which was formerly thought useful in chronic catarrh, consumption, and other pectoral complaints; but inconvenience arose from its acrid properties, and its internal use was abandoned. It is sometimes applied as a stimulant to foul ulcers. The dose is from five to thirty minims (0.3–1.8 Cc.).

Balsam Wood. *Palo Balsamo.*—This is a South American wood, derived from an unknown tree, which is believed to contain *guaiacin*, and which yields to distillation nearly six parts of a thick viscous aromatic oil. This contains as its chief constituent a crystalline solid of alcoholic char-

acter melting at 91° C. (195.8° F.) and corresponding closely to the formula $C_{14}H_{24}O$. It has found employment in perfumery. (Schim. Rep., April and Oct. 1892.)

Balsamorhiza. *Balsamorhiza terebinthinacea* (Hook.), Nutt. (Fam. Compositæ).—The root of this plant, obtained from Idaho and Oregon, has a strong terebinthinate odor, and is used medicinally in the Western States. It contains volatile oil, fixed oil, resin, organic acid, and sugar (Herman T. Kelly, D. C., 1897, 32).

Baptisia. *Baptisia tinctoria* (L.), R. Br. *Sophora tinctoria*, L. *Podalyria tinctoria*, Michx. Wild Indigo. *Indigo sauvage*, Fr. *Baptisie*, G. (Fam. Leguminosæ).—This is an indigenous perennial plant, abundant throughout the Eastern United States, in woods and dry barren uplands. The root, which is used medicinally, is of a dark brown color, of a slight peculiar odor in the dried state, and of a nauseous, bitter, somewhat acrid taste. Its virtues appear to reside chiefly in the cortical portion. B. L. Smedley thought that he had found in it a peculiar alkaloid. (A. J. P., July, 1862, 311.) Jno. A. Weaver has shown this to be a salt of lime. (A. J. P., xlii, 251.) F. V. Greene, U. S. N., obtained in a crystalline condition the hydrochloride of an alkaloid. (A. J. P., 1879, 577.) Von Schroeder (Ph. Post, Oct. 1885) affirms that there are in baptisia root three active principles: a glucoside, *baptisin*, insoluble in water; a glucoside, *baptin*, soluble in water, and an alkaloid, *baptitoxine*. Of these baptisin is an indifferent, bitter substance, baptin a feeble laxative, and baptitoxine an active poison, causing at first acceleration of respiration and increase of reflex activity, and afterwards death from central paralytic asphyxia. Plugge (A. Pharm., 233, 4te Heft, 1895) finds the alkaloid of *Baptisia tinctoria* to be *cytisine*. K. Gorter (A. Pharm., No. 5, p. 235, 1897, p. 321) investigated baptisin and by hydrolyzation produced *baptigenin*. By boiling this with solution of sodium hydroxide he obtained *baptigenetin*. He believes baptitoxine to be identical with cytisine. He examined Merck's baptisin and obtained crystalline needles of *pseudobaptisin*, $C_{27}H_{30}O_4$. Both the seeds and root contain the alkaloid. For a process for preparing baptisin, see Ouch's method (C. D., 1897, p. 524). In large doses wild indigo is said to operate violently as an emetic and cathartic; in smaller, to produce only a mild laxative effect. Stevens has employed a decoction of the root advantageously in epidemic dysentery. (N. Y. M. J., iv, 358.) A pale blue coloring substance has been prepared from the plant as a substitute for indigo, but is greatly inferior. Another species, *B. alba* (L.), R. Br., or *prairie indigo*, which is abundant on our northwestern prairies, is said to have similar properties, and to be sometimes used as a substitute for *B. tinctoria*.

Barbados Nuts. *Purging Nuts.* *Physio Nuts.* *Semen Ricini Majoris.* *Pignon d'Inde* (des Barbades), *Semences du Médecinier*, Fr. *Purgirnuss*, *Schwarze Brechnuss*, G.—These are the seeds of the *Curcas purgans*, Adanson (*Jatropha Curcas*, L.) (Fam. Euphorbiaceæ), growing in Brazil, the West Indies, and on the western coast of Africa. The fruit is a three-celled capsule, containing one seed in each cell, and is about the size of a walnut. The seeds are blackish, oval, about eight lines long, flat on one side, convex on the other, and the two sides present a slight longitudinal prominence. They yielded to Soubeiran fixed

oil, an acrid resin, sugar, gum, a fatty acid, glutin, a free acid, and salts. A. Siegel (*Bot. Centralbl.*, xlvii, 120) found in the seeds a poisonous principle, *curcin*, which he states is analogous to *ricin*, and places in the class of toxalbumins. The oil may be separated by hot expression. When fresh it is without odor or color, but becomes yellowish and slightly odorous by time. When cold it deposits a white substance, which is probably *palmitin*. Alcohol does not readily dissolve it. It is sometimes called *jatropha oil*. It is colorless, odorless, of sp. gr. 0.91 at 19° C. (66.2° F.), solidifies to buttery consistence at -8° C. (17.6° F.). Bouis believed it to be the glyceride of a peculiar acid, *isocetic acid*, but it is now considered to be a mixture of *palmitin* and *myristin*. Its purging quality is, however, undoubtedly due to the presence of *ricinoleic acid*. From three to five of the seeds, slightly roasted and deprived of their envelopes, operate actively as a cathartic, and not infrequently produce nausea and vomiting, with a sense of burning in the stomach. The oil purges in the dose of twelve or fifteen drops (0.6-0.75 Cc.), and is analogous in its action to croton oil, though less powerful. The cake left after the expression of the oil is an acrid emeto-cathartic, operating in the dose of a few grains. Either of these substances may produce serious consequences in overdoses. The leaves of the plants are rubefacient, and the juice is said to have been usefully employed as a local remedy in piles. (*A. J. P.*, 1893, 335.) The seeds of *Curcas multifidus* (L.), Endl. (*Jatropha multifida*, Linn.), have similar properties, and yield a similar oil. This species also grows in Brazil and the West Indies. (See Peckoldt, *A. Pharm.*, 1887, 415.)

Jatropha gossypifolia, Linn., of South America, is used as a local application in *leprosy* and to indolent ulcers, and probably has similar physiological influence to curcas. *Jatropha urens*, L., must be excessively poisonous, as accidental contact of the wrist of a gardener in Kew with a young plant produced such symptoms that for five minutes the man was thought to be dead. (*P. J.*, April, 1872, 863.)

The roots of the *Jatropha cardiophylla*, Muell. Arg., are largely employed in Southern Arizona and Mexico for tanning purposes. According to the analysis of Josiah C. Peacock they contain, when thoroughly dried, over 5 per cent. of tannic acid. (*A. J. P.*, 1900, 432.)

Barium Chloride. *Barii Chloridum. U. S.* 1870. *Chlorure de Baryum*, Fr. *Chlorbarium, Chlorbaryum*, G. $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$.—Take of Carbonate of Barium, in small pieces, Muriatic Acid, each, *four troyounces*; Water *a pint*. Mix the Acid with the Water, and gradually add the Carbonate of Barium. Towards the close of the effervescence apply a gentle heat, and when chemical action has ceased, filter the liquor, and evaporate so that crystals may form when it cools." *U. S.* 1870. Another plan is that which procures it from the sulphate, as directed in the old Edinburgh Pharmacopœia. In this the sulphate, previously ignited and powdered, is mixed with charcoal and exposed to a low white heat, by which its constituents are deoxidized, and barium sulphide produced, the oxygen escaping in combination with the carbon as carbon dioxide. The barium sulphide, after having been dissolved in water, is decomposed by the addition of hydrochloric acid, hydrogen sulphide being evolved, and barium chloride formed in solution, from

which, in the usual manner, the solid salt is obtained. The reactions for these two processes are:

Of these processes, that in which the native carbonate is used is the simplest and most convenient; but the carbonate is comparatively a rare mineral, and, as the sulphate in fine powder is a cheap article of commerce under the name of *blanc fixe*, or *permanent white*, and the most abundant ore is also the native sulphate (barytes), this compound is almost always used for obtaining barium chloride and the other barium salts.

Barium chloride is a permanent white salt, possessing a bitter and disagreeable taste. It crystallizes in rhombic tables with beveled edges. It dissolves in about two and a half times its weight of cold water, and in a little more than its own weight at 106° C. (222.8° F.), the boiling point of a saturated solution. It is scarcely soluble in absolute alcohol, but dissolves in rectified spirit. Alcohol impregnated with it burns with a greenish flame. When exposed to heat, it decrepitates and loses its water of crystallization, and at a red heat fuses. It is decomposed by the sulphates, oxalates and tartrates, and the alkaline phosphates, borates, and carbonates; also by silver nitrate, mercurous salts, and lead acetate. When pure it does not deliquesce. Its solution is not affected by ammonia, which proves the absence of aluminum and ferric oxide, or by hydrogen sulphide, which shows that neither copper nor lead is present.

After the whole of the barium has been precipitated by an excess of sulphuric acid, the supernatant liquid is shown to be free from lime by the non-action of sodium carbonate. If strontium be present, an alcoholic solution of the salt will burn with a red flame.

Medicinal Properties.—Rabuteau found that the intravenous injection of barium chloride produced in the dog a sudden cry, convulsions, and death, with remarkable fibrillary muscular contractions, continuing after death. Laborde (*B. A. M.*, July, 1891) has shown that when the chloride is very slowly injected, the heart beats become slower, the pupils dilate, the animal shrieks, and death occurs from centric arrest of the respiration, the blood and the muscles, after death, remaining of a bright red color. Given by the mouth, it produced in the dog vomiting, choleraic diarrhœa, paresis, collapse, and death. After small doses, barium has been found by Krahmer and by J. Neumann in the liver, kidney, spleen, lungs, and nerve centres, and especially abundant in the bones. (*A. G. P.*, Bd. xxxvi.) In a case reported by Ogier and Socquet (*Annales d'Hygiène Publ.*, May, 1891) death followed in five hours the ingestion of three hundred grains (19.4 Gm.). Bardet (*S. M.*, Dec. 1891) reports recovery after sixty grains (3.9 Gm.). Barium chloride has been employed in *sclerostis* of the nerve centres, but is of no value. It may prove to be a useful heart stimulant, since it is asserted by Lauder Brunton, confirmed by H. A. Hare, that in small doses it is a rapidly acting stimulant to the heart, steadying its rhythm and increasing the volume and force of the blood thrown out by the systole. (*Pract.*, June, 1889.) *Liquor Barii Chloridi, U. S.* 1870 (a troyounce of barium chloride in three fluidounces of water) is given in five minim (0.3 Cc.) doses.

Barium Dioxide. *Barii Dioxidum.* U. S. 1890. *Barium Peroxide.* $\text{BaO}_2 = 168.16$.—"Commercial, anhydrous Barium Dioxide. It should be kept in well-closed vessels." U. S. 1890.

It is used solely for making hydrogen dioxide. Barium forms two oxides, BaO and BaO_2 ; the former is produced by the action of oxygen or dry air on barium. Barium dioxide, BaO_2 , is made by heating barium oxide to about 450°C ., when it takes up another atom of oxygen. It is "a heavy, grayish-white, or pale yellowish-white, amorphous, coarse powder, odorless and tasteless. When exposed to the air, it slowly attracts moisture and carbon dioxide, and is gradually decomposed. Almost insoluble in cold water, with which, however, it forms a definite hydrate, and to which it imparts a decidedly alkaline reaction. Hydrochloric, phosphoric, and most other mineral acids decompose it, producing the corresponding barium salts, and hydrogen dioxide, which remains in solution for a considerable time, if the reaction has taken place in the cold, and an excess of the acid is present. When heated to a bright red heat, Barium Dioxide fuses, loses oxygen, and is reduced to barium oxide. Barium Dioxide should be dissolved by diluted hydrochloric or phosphoric acid without leaving more than a trace of residue. If 2.11 Gm. of Barium Dioxide be dissolved, as completely as possible, in ice-cold water to the volume of 25 Cc., with the aid of 7.5 Cc. of phosphoric acid, and 5 Cc. of this solution (corresponding to 0.422 Gm. of the Dioxide) be measured off for assay, it should require not less than 40 Cc. of decinormal potassium permanganate volumetric solution to impart to the liquid a permanent pink tint, corresponding to not less than 80 per cent. of pure Barium Dioxide (each Cc. of the volumetric solution indicating 2 per cent. of the latter)." U. S. 1890.

Barium dioxide is not used medicinally.

Barium Iodide. *Barii Iodidum.* *Iodure de Barium*, Fr. *Jodbarium*, G. BaI_2 .—This compound may be formed by double decomposition, by adding native barium carbonate in powder to a boiling solution of ferrous iodide. M. Henry, Jr., obtained it by decomposing a solution of barium sulphide by a concentrated alcoholic solution of iodine. Sulphur is precipitated, which is separated by filtration, and barium iodide formed in solution, from which it is obtained in the solid state by rapid evaporation to dryness. Barium iodide crystallizes in small, colorless needles, which deliquesce slightly, and are very soluble in water. The solution promptly undergoes decomposition on exposure to the air, barium carbonate being precipitated, and iodine set free, which colors the solution. It has been used with advantage by Jahn and Lugol, as an alternative, in *scrofulous affections* and morbid growths. The dose is an eighth of a grain (0.008 Gm.) three times a day, gradually increased to three grains (0.2 Gm.).

Barium Sulphate. *Barii Sulphas.* BaSO_4 . (See *Barium Chloride*.)—Barium sulphate is a heavy, lamellar, brittle mineral, varying in sp. gr. from 4.4 to 4.6. It is generally translucent, but sometimes transparent or opaque, and its usual color is white or flesh-red. When crystallized, it is usually in very flat rhombic prisms. Before the blowpipe it strongly decrepitates, and melts into a white enamel, which, in the course of ten or twelve hours, falls to powder. It is thus partially converted into barium sulphide, and, if applied to the tongue, will give a taste like that of putrid

eggs, from the formation of hydrogen sulphide. This salt, on account of its great insolubility, is not poisonous. It is, however, soluble in a great excess of diluted hydrochloric acid. (*Chem. News*, 1871, 69.) Ground to fine powder it is often mixed with white lead, but impairs the quality of that pigment. The artificial barium sulphate, under the name of *permanent white* or *blanc fixe*, is much used in the arts as a water-color. It is made from both the native sulphate and carbonate. It forms a dazzling white color, unalterable by light, heat, air, or hydrogen sulphide.

Barringtonia. *Barringtonia speciosa*.—The large Indo-Malayan tree, *Barringtonia speciosa*, Forst., contains, according to Maresuw, 3.3 per cent. of *barringtonin*, a colorless, amorphous glucoside, having the formula $\text{C}_{12}\text{H}_{22}\text{O}_{10}$, and belonging to the saponin group. It is said to be an active cardiac poison. (*S. W. P.*, xli. 1903, pp. 423, 435.)

Bassora Galls are cultivated in Persia and Asia Minor, and are exported by way of Smyrna for tanning purposes. They come into commerce ground and pressed into the form of bricks. They contain, on an average, 27 per cent. of tannin.

Bassora Gum. *Caramania Gum.* *Hog Gum.* *False Tragacanth.* *Kutera Gum*.—This substance came into commerce originally from the neighborhood of Bassora, on the Gulf of Persia; but is often found mixed with gum brought from other countries, and is said to be the product of the almond and plum trees. It is in irregular pieces, of various sizes, never very large, brown or yellow, intermediate in the degree of its transparency between gum arabic and tragacanth, inodorous, tasteless, and possessed of the property of yielding a slight sound when broken under the teeth. But a small portion of it is soluble in water, whether hot or cold. The remainder swells up considerably, though less than tragacanth, and does not, like that substance, form a gelatinous mass, as it consists of independent granules which have little cohesion. The soluble portion is pure gum or *arabin*, and, according to Guérin, constitutes 11.2 per cent. The insoluble portion consists of *bassorin*, associated with a small proportion of saline substances, which yield, when the gum is burnt, 5.6 per cent. of ash. The gum is employed only to adulterate tragacanth, and for this purpose is sometimes whitened by means of white lead.

Batiator Root.—The root of the *Vernonia nigritiana*, Oliver and Hiern. (Fam. Compositæ), a widely distributed plant of West Africa, is said to be largely used in Senegal as a febrifuge, emetic, and anti-dysenteric, resembling ipecac somewhat in its therapeutic application. The plant is a composite which climbs to the height of a foot and a half, and yields a root composed of numerous fibres from twenty to thirty centimeters long, slender and grayish yellow externally, a number of which are united to form an irregular knotty rhizome, unequally spherical at the neck or crown, and covered at this point with silky hairs. The active constituent is a glucoside, *vernoinin*, $\text{C}_{10}\text{H}_{24}\text{O}_7$. (Heckel and Schlagdenhaufen, *A. de P.*, Aug. 1888. See also *Zeit. An. Chem.*, 1893, p. 364.) This is a hygroscopic whitish powder, forming a pale yellow solution with water, and only slightly soluble in ether and in chloroform. By the absorption of 2 molecules of water it is split into a resinous body and glucose. Physiological experiments made upon frogs show vernoinin to be a cardiac poison

comparable to digitalin, but about twenty-four times less active; it is also said to act as a paralyzant to the motor nerve trunks. (P. J., June 30, 1888.)

Baume Tranquille. *Balsamum Tranquillans.* This is a preparation of some note, directed by the French Codex, and consisting essentially of olive oil holding in solution the active matters of certain narcotic and aromatic plants. According to the Codex the fresh plants (belladonna, henbane, etc.) are boiled with the oil in a copper kettle until all their water is driven off, and a gentle heat maintained until the oil acquires a fine green color; the oil is then expressed and the essential oils of thyme, rosemary, peppermint, and other plants are added. The preparation is used externally by friction as an anodyne in local pains, but especially to relieve *earache*, a few drops being placed in the ear on a pledget of cotton. For old formula see J. P. C., August, 1862, 121. An improved process was proposed by W. C. Bakes. (A. J. P., 1862, 22.) We have still further modified this, and the formula is as follows. Take of Alcoholic Extracts of Belladonna, Conium, Hyoscyamus, and Stramonium, each 30 grains; Aqueous Extract of Opium, 12 grains. Soften the extracts with one fluidounce of Boiling Water, and add four fluidounces of Olive Oil. Digest this mixture with a gentle heat until the water has been evaporated, and then strain or filter. To this add one minim of each of the following volatile oils: Sage, Wormwood, Lavender, Thyme, Peppermint, Rue. It should be used with care.

Baycuru Root.—This is the root of a Brazilian plant, probably the *Statice brasiliensis*, Boiss. (Fam. Plumbaginæ), which is used by the natives as a discutient in glandular swellings and as an astringent gargle. F. A. Dalpe (A. J. P., xiv. 361) believes that he has found in it an alkaloid, *baycurine*, besides volatile oil, gum, glucose, etc. C. Symes found in it 12.5 per cent. of tannic acid. (Newer Mat. Med., 51.)

Bdellium.—Under this name have been included various gum resins having little or nothing in common. The commercial Bdelliums are naturally divided into the Indian and the African, but E. M. Holmes, in an elaborate study (P. J., lxi.), recognizes five commercial varieties of African Bdellium,—namely, 1. Perfumed Bdellium, which is believed to be collected in Northeastern Africa; 2. African Bdellium; 3. Opaque Bdellium; 4. Hotai Bdellium from the Somaliland, and 5. Non-aromatic acrid gum resin. *Perfumed Bdellium*, or *Habaghadi*, closely resembles in appearance *Somali myrrh*, but has a less bitter, more acrid and peculiar taste which distinguishes it at once from *myrrh*. *African Bdellium*, proper, occurs in hard, roundish pieces, of a pale to dark grayish-brown color with a resinous unstreaked fracture, dotted with glistening points. The odor is said to recall that of cedar pencils; the taste is slightly acrid but not bitter. *Opaque Bdellium* is of a pale brown color and has a bitter, slightly acrid taste and cedar-like odor; it occurs in tough, roundish pieces about an inch to an inch and a half in diameter. *Hotai Resin* resembles opaque bdellium, but is distinguished by its lack of odor, its slightly soapy taste, and its brittleness. These four bdelliums of Holmes are for the most part collected in Somaliland. They are the product of different species of *Commiphora*, small trees or large shrubs which suggest in appearance the English hawthorn. The species are by Holmes

divided into four groups. (See P. J., lxxii.) According to A. Engler, the resin of *Commiphora roxburghiana* (Stocks), Engl., is the commercial *Gugul*, or *India Bdellium*, which is employed in the East Indies as a remedy for *leprosy*, *rheumatism*, and *syphilis*. Bdellium sometimes comes mixed with gum arabic and gum senegal. It is either in small roundish pieces, of a reddish color, semi-transparent, and brittle, with a wax-like fracture, or in large irregular lumps, of a dark brownish-red color, less transparent, somewhat tenacious, and adhering to the teeth when chewed. It has an odor and taste like that of *myrrh*, but weaker. It is infusible and inflammable, diffusing while it burns a balsamic odor. According to Pelletier, it consists of 59 per cent. of resin, 9.2 of gum, 30.6 of bassorin, and 1.2 of volatile oil, including loss. In medicinal properties it is analogous to *myrrh*, and was formerly used for the same purposes. In Europe it is still occasionally employed in plasters. The dose is from ten to forty grains (0.65–2.6 Gm.).

Bebeeru Bark.—*Nectandra Cortex*, Br. 1885, is the dried bark of *Nectandra Rodiei*, Hook. (*N. Rodiei*, Schomb.) (Fam. Lauracæ). The *bebeeru*, *bibiru* or *sipiri*, as it has been indifferently named, is a tree sixty feet or more in height, growing in Guiana and the neighboring regions of South America, and yielding the wood known as *greenheart*.

The bark occurs in large, flat, heavy pieces, from one to two feet long, from two to six inches broad, and three or four lines thick, with a rough and somewhat fibrous fracture, of a grayish-brown color on its outer surface and a dark cinnamon color on the inner. It has an intensely bitter, somewhat astringent taste. On microscopical examination it is seen to be composed chiefly of very thick-walled parenchymatous cells. The inner liber contains peculiar short, sharp-pointed, saw-shaped liber cells. Within the cells dark brown masses (colored greenish black by ferrous sulphate) may be seen. Analyzed by MacLagan of Edinburgh, it was found to contain tannic acid of the kind that precipitates the salts of iron green, resin, gum, sugar, albumen, fibrin, various salts, and two peculiar alkaloids, named respectively *bebeerine*, $C_{13}H_{21}NO_3$, and *sipirine*, the former soluble and the latter insoluble in ether. In the seeds, besides the foregoing principles, MacLagan found 53 per cent. of starch, and a peculiar white, crystalline, volatile acid, which he named *bebeeric acid*. The alkaloids are extracted together from the bark, in the form of impure sulphates, by a process similar to that for preparing quinine sulphate. This preparation is known as the *commercial bebeerine sulphate*. The official process of the Br. Pharmacopœia of 1885 also yielded an impure alkaloid. The alkaloid was obtained pure by MacLagan and Tilley by the following process: The impure sulphate is dissolved in water and precipitated by ammonia. The precipitate, mixed with an equal weight of recently precipitated lead oxide, and dried, is treated with absolute alcohol, which, being evaporated, leaves the two alkaloids in the form of a translucent resinoid mass. The *bebeerine* is separated by means of ether, which yields it by evaporation. Another process is to dissolve the precipitate obtained by ammonia, previously washed, in diluted acetic acid, add lead acetate, precipitate by *potassium hydroxide*, exhaust the precipitate by strong ether, evaporate the solution until syrupy, dissolve the residue in abso-

lute alcohol, and pour the solution gradually into water. A flocculent deposit is formed, which when washed and dried, is the alkaloid in question. Flückiger found the commercial article to yield a very trifling amount, less than 25 per cent. of the pure alkaloid. It is in dark brown translucent scales, yellow when reduced to powder, of a strongly bitter taste, and soluble in water and alcohol. According to Flückiger (*P. J.*, xi. 193, 1869), pure bebeerine is a white, amorphous powder, whose concentrated aqueous solution is not precipitated by tartar emetic, but affords abundant white precipitates with sodium phosphate, potassium nitrate, iodide, or iodohydrargyrate, mercuric chloride, potassium platino-cyanide, and nitric or iodic acid. Its acetate yields yellow amorphous precipitates with potassium ferrocyanide, or potassium ferricyanide, potassium chromate, potassium dichromate, and platinum dichloride. D. B. Dott has confirmed the results of Flückiger's examination, although he found a larger percentage of alkaloids than the latter did. Owing to the difficulty of obtaining the alkaloids in crystals, it was almost impossible to ascertain the quantity present. (*Y. B. P.*, 1881, 442; 1885, 420.) Bebeerine was asserted by Walz in 1860 to be identical with *buzine*, obtained from *Buzus sempervirens*. This statement was confirmed by Flückiger, who proved that *pelosine* was identical with both of the above principles. (*P. J.*, xi. 1870, 192.) The alkaloid dried at 100° C. (212° F.) has the formula $C_{18}H_{21}NO_3$. (Palen gives $C_{19}H_{21}NO_3$ as the formula.)

By treating the mixed alkaloids obtained from the wood with chloroform, Douglas MacLagan and Arthur Gamgee have separated an alkaloid, *nectandrine*. It is a white powder, amorphous, and intensely bitter. It differs from bebeerine in being much less soluble in ether, and, when treated with strong sulphuric acid and manganese dioxide, in giving rise to a magnificent green, slowly passing into a beautiful violet, and, lastly, in having a higher molecular weight, its formula being $C_{20}H_{23}NO_4$. After separating nectandrine from the mixed bases, the authors succeeded in extracting another alkaloid, different from bebeerine, much more soluble in water than nectandrine, but insoluble in chloroform. (*A. J. P.*, 1869, 453.)

Nectandra is tonic, somewhat astringent, and febrifuge, resembling cinchona in its virtues, though much inferior, at least in antiperiodic power. It has generally been employed in the form of the impure bebeerine sulphate, and sometimes with great asserted success, in the treatment of *intermittent and remittent fevers*. Rodie recommended it as early as 1834; but later experience shows that, though frequently successful, it often fails, and cannot be relied on as a substitute for quinine. From twenty grains to a drachm (1.3–3.9 Gm.) may be given between the paroxysms, in doses of two grains (0.13 Gm.). Bebeerine sulphate has been given in *dysmenorrhœa*, *menorrhagia*, and *leucorrhœa*, and in *blemnorrhœal discharges*. The dose is from two to five grains (0.13–0.32 Gm.).

Bedeguar. *Fungus Rosarum*.—An excrescence upon the sweetbrier or *eglantine*, and other species of *Rosa*, produced by the puncture of insects, especially by one or more species of *Cynips*. It is of irregular shape, usually roundish, about an inch in diameter, with numerous cells containing larvæ. It is nearly odorless, of slightly astringent taste,

and was formerly considered a diuretic and anthelmintic. *Dose*, from ten to forty grains (0.65–2.6 Gm.).

Benzaceticin. *Acet-amido-ethyl Salicylic Acid*.
 $C_6H_5 \left\{ \begin{array}{l} OC_2H_5 \\ NH.COCH_3 \\ COOH \end{array} \right.$ —This occurs in colorless crystals, melting at 205° C. (401° F.), sparingly soluble in water. It has been recommended by Frank as an analgesic in *migraine* and other forms of *neuralgia*, and as a sedative in nervous excitement. It has been used with alleged excellent results in conjunction with caffeine, ten parts to one. *Dose*, from eight to fifteen grains (0.5–1.0 Gm.) two or three times a day, or repeated in an hour for relief.

Benzanilide.—*Phenylbenzamide*, $C_6H_5NH(C_7H_5O)$, is closely related to acetanilide, containing the benzoyl radical C_7H_5O instead of the acetyl radical C_2H_3O . White, crystalline, odorless powder melting at 163° C. (325.4° F.), practically insoluble in water but soluble in alcohol. This substance has been recommended by Cahn as an antipyretic in diseases of children in doses of from one and a half to three grains (0.096 to 0.2 Gm.) for children one to three years of age, and three to six grains (0.2 to 0.4 Gm.) when from four to eight years old. Forty-five grains (3 Gm.) can be given to the adult without injury. It has been little used.

Benzo-Iodo-Hydrine.—Prepared by mixing *benzoyl iodide* and *epichlorhydrin*. It forms a brown, fatty mass, soluble in ether, alcohol, and petroleum oils, insoluble in glycerin. It is decomposed at 100° C. (212° F.), with separation of iodine. For dispensing, it is usually mixed with powdered sugar, so that the mixture contains 3½ per cent. of benzo-iodo-hydrine, and a teaspoonful is about the equivalent of sixteen grains of potassium iodide. It is used as a substitute for potassium iodide, because of its freedom from irritating properties and from tendency to produce iodic poisoning.

Benzo-Naphthol. *Benzoyl-Naphthol*. β -*Naphthyl Benzoate*, $C_{10}H_7O(C_7H_5O)$.—A compound of β -naphthol and benzoic acid, made by the action of benzoyl chloride upon β -naphthol. It is a whitish crystalline powder, without taste or odor, melting at 110° C. (230° F.). It occurs in microscopical crystals, almost odorless and tasteless, nearly insoluble in water at ordinary temperatures, more soluble in alcohol, with solubility rising rapidly with the temperature, but most soluble in chloroform. "A hot alcoholic solution should not give any cherry-red coloration when an equal volume of nitric acid and a few drops of mercuric nitrate solution are added, which would indicate the presence of free β -naphthol." This substance, which was proposed by Yvon and Berlioz (*Praet.*, Dec. 1891) as especially efficacious as an intestinal antiseptic, has been reported upon by Gilbert (*S. M.*, May, 1892), who affirms that it is of little value in *gastric fermentation*, but very valuable in *intestinal fermentation*. It is probably slowly broken up in the intestines into benzoic acid and naphthol, and the experiments made by Ewald (*B. Z. W.*, 1892) indicate that it has a positive influence upon intestinal fermentation, a conclusion confirmed by various French clinicians. It appears to be free from irritant properties, and to be a very useful remedy in chronic *diarrhœa*; also in *senile pruritus* dependent upon intestinal indigestion. It is best administered in small doses of from four to eight grains (0.26–0.5 Gm.), re-

peated frequently, in capsule; as much as seventy-five grains (5 Gm.) daily may be given to an adult.

Benzo-Phenoneid. *Tetra-methyl-diapsido-benzo-phenoid*.—This substance, which is soluble in 100 parts of water, has been proposed by Galezowski as a non-irritant and efficient germicide, and as a local application in ulcerative diseases of mucous membranes or skin. (*L. L.*, Jan. 1891.)

Benzoin. *Benzoin Benzoin* (*L.*), *Coulter*, *Lindera Benzoin*, *Blume*, *Laurus Benzoin*, *L.* (*Fam. Lauraceae*.) *Spicewood*, *Spice-bush*, *Fever-bush*, *Wild Allspice*, *Laurier Benzoin*, *Fr. Benzoclorbeer*, *G.*—An indigenous shrub, all parts of which have a spicy, agreeable flavor, strongest in the bark and berries. By warming and expression A. W. Miller obtained from the berries 50 per cent. of oily material, which, on distillation, yielded about 2 per cent. of volatile oil. The latter had a sp. gr. of 0.850, was thin, bright green, of a warm aromatic taste, and a fragrant odor. J. M. Jones found it to be of the cinnamyl series. (*Proc. A. Ph. A.*, xxvi. 772; also *A. J. P.*, xlv. 300; xlvii. 246.) The small branches are said to be employed in the form of infusion or decoction, by the country people, as a vermifuge, and an agreeable drink in low fevers, and the bark has been used in intermittents. The berries, dried and powdered, were sometimes substituted, during the Revolutionary War, for allspice. The oil is feebly aromatic. (*A. J. P.*, xlv. 300; *Ibid.*, xlvii. 246.)

Benzosol. *Benzoyl Guaiacol*, *Guaiacol Benzoate*.—A colorless crystalline powder, almost free from odor and taste. It melts at 59°C . (138.2°F .) It is prepared from guaiacol, $\text{C}_6\text{H}_4\left\{\begin{smallmatrix} \text{OCH}_3 \\ \text{OH} \end{smallmatrix}\right.$

and benzoyl chloride, or benzoic acid, and has the formula $\text{C}_6\text{H}_4\left\{\begin{smallmatrix} \text{OCH}_3(1) \\ \text{OCO.C}_6\text{H}_5(2) \end{smallmatrix}\right.$ The compound is insoluble in water, soluble with difficulty in hot glacial acetic acid, readily so in chloroform, ether, and hot alcohol. In the digestive tract, it soon splits up into guaiacol and benzoic acid; this decomposition occurs partially in the stomach, but chiefly in the small intestine. It is said to appear in the urine as guaiacol and benzoic acid, and their derivatives.

Benzosol was first made by Bougartz, and highly commended by Walzer and Hughes (*D. M. W.*, 1891) as a substitute for creosote in *phthisis*, and has been used to a considerable extent by clinicians as an intestinal antiseptic in *intestinal indigestion*, *diarrhœa*, *typhoid fever*, and other conditions. It has also been used successfully in *cystitis*, and is affirmed by Piatkowski, J. Blake White, and others to be valuable in the treatment of *diabetes*. Summerbrodt has given it continuously in *phthisis* with excellent results in doses of twenty-four grains (1.6 Gm.) a day, and it is probable that larger amounts may be safely administered.

Benzoyl-acetyl-peroxide. *Benzozone*, *Acetozone*, $\text{C}_6\text{H}_5\text{CO.O.O.CH}_3\text{CO}$.—The pure peroxide forms a white crystalline mass melting at 36.6°C . (98°F .) When gradually heated it slowly decomposes and evaporates; if suddenly heated it almost instantly decomposes and in a tightly-stoppered bottle an explosion will follow. Grinding, compressing, or pounding the undiluted substance will often bring about the same result. In crystalline form, the substance is soluble in oils to the extent of about 5 per cent., slightly soluble in alcohol, moderately soluble in ether, chloroform,

and carbon tetrachloride, although gradually decomposed by all the solvents with the exception of neutral petroleum oils. It is decomposed by contact with alkaloids and organic matter of all kinds. It is slowly hydrolyzed and decomposed by water. Acetozone of the markets is benzoyl-acetyl-peroxide diluted with a neutral drying powder so that 50 per cent. of the pure article is represented. Benzoyl-acetyl-peroxide is moderately soluble in water so that fifteen grains of it may be dissolved in one-half gallon of boiled or distilled water, and the solution should be used within thirty-six hours after it is made. If the commercial drug be employed thirty grains may be used in the half gallon; the solution should be allowed to settle and be decanted without filtration.

Benzoyl-acetyl-peroxide is a very active germicide. Experiments in the laboratories of the United States government in the Philippines show that 1 part of the hydrolyzed substance to 177 of water, and containing only 0.05 per cent. of active oxygen, destroys all germs, including spores, almost instantly, and even at a dilution of 1 in 3000, vegetating germs, as a rule, are killed within one minute, but the spores require an appreciable time. On comparing these results with similar ones with hydrogen dioxide, 1 in 1000, and phenol 5 per cent., it was shown that hydrogen dioxide, although it contained ten times as much active oxygen as the solution of benzoyl-acetyl-dioxide, was by no means as effective, and the same may be said of phenol.

It was further shown that 1 part in 1000 absolutely destroys and that 1 in 30,000 distinctly inhibits the growth of the comma bacillus. In the experiments of Ferer and Novy (*Am. Chem. J.*, vol. xxvii., No. 3, March, 1902), one drachm (3.9 Gm.) of it a day, for weeks, given a dog weighing eight kilos, produced no sensible effect. Charles L. Bliss has shown that the peroxide is eliminated in the form of hippuric acid. In internal medicine benzoyl-acetyl-peroxide has been used in the United States hospitals with most excellent results in the treatment of *cholera*, given in double capsules in doses of from three to five grains (0.2–0.32 Gm.) every two to four hours. It was found that when the stomach was full at the time of administration vomiting frequently occurred, probably being due to the decomposition of the peroxide by the organic matter present, since no irritation was produced when the stomach was empty. Benzoyl-acetyl-peroxide has been employed primarily by Wasdin, and subsequently by Harris and others (*T. G.*, 1902–1903), in *typhoid fever* with alleged most extraordinary results in the reduction of the local and general symptoms,—one hundred and thirty to two hundred and ten grains (8.3–13.6 Gm.) being administered in the twenty-four hours. Acetozone has also been employed locally as a germicide with excellent results in *gonorrhœa*, *malignant œdema*, *tinea tonsurans*, *infected ulcers*, and similar affections. In surgical cases acetozone may be applied directly to the wound. When used as an intestinal antiseptic in typhoid fever or in conditions similar to those resulting from this disease, a 1 in 1000 solution should be freshly prepared each day, and administered almost *ad libitum*.

Benzoyl Ecgonine.—This substance is made by heating cocaine in aqueous solution to decomposition. For details, see Paul, *P. J.*, Oct. 17, 1885, March 27, 1886; also, Skrapu, *Sitzungsber. Wiener Akad.*, 1885. The reaction consists in the substitution in cocaine [$\text{C}_{16}(\text{CH}_3)\text{H}_{18}\text{NO}_4$] of an

atom of hydrogen (H) for the methyl group (CH_3). There results $\text{C}_{18}(\text{H})_2\text{H}_{18}\text{NO}_4$ or $\text{C}_9\text{H}_{14}(\text{C}_7\text{H}_5\text{O})\text{NO}_3$ = benzoyl eugonine; while CH_3OH (methyl alcohol) is formed at the same time. M. R. Stockman (*J. A. P.*, vol. xxi.) finds that it acts like caffeine, but less powerfully. It does not paralyze the sensory nerves.

Benzoyl-Eugenol.—*Benzoeugenol*, $\text{C}_{10}\text{H}_{11}(\text{C}_7\text{H}_5\text{O})\text{O}_2$, occurs in colorless prisms or crystals, melting at 70.5°C . (158.9°F .), soluble in alcohol, ether, and chloroform, insoluble in water. It is similar in its properties and medicinal uses to *cinnamyl-eugenol*, $\text{C}_{19}\text{H}_{18}\text{O}_3$. Both are used as antiseptics and in the treatment of *tuberculosis*.

Benzoyl Tropeine, $\text{C}_{15}\text{H}_{19}\text{NO}_2 + 2\text{H}_2\text{O}$, is formed by heating tropine with benzoic and dilute hydrochloric acids to 100°C . (212°F .), when the benzoyl radical, $\text{C}_7\text{H}_5\text{O}$, derived from benzoic acid, $\text{C}_6\text{H}_5\text{COOH}$, replaces a hydrogen atom of the tropine, $\text{C}_8\text{H}_{15}\text{NO}$, and $\text{C}_8\text{H}_{14}(\text{C}_7\text{H}_5\text{O})\text{NO}$ is produced. It forms silky needles, fusing at 58°C . (136.4°F .). When deprived of water, the anhydrous base fuses at from 41° to 42°C . (105.8° to 107.6°F .), and can be sublimed without decomposition. It has a strong basic reaction, and its salts are not very soluble.

Filehne (*B. K. W.*, vii. 1887) has found that benzoyl tropeine is a powerful local anæsthetic, also affecting the pupil and accommodation like other tropeines. He also found other benzoyl compounds to be local anæsthetics, *benzoyl methyl-triacetonalkamine* being the most powerful, *benzoyl quinine* next, *benzoyl morphine* the least.

Berberis.—This genus belonging to the natural order *Berberidaceæ* comprises various shrubs having a yellow inner bark and wood, probably most of which are more or less medicinal. The bark of the root of *B. vulgaris*, L., was formerly included in the secondary list of the U. S. Pharmacopœia, under the name of *Berberis*. *Berberis aquifolium* is official in U. S. P. 8th Revision (see page 236). *Berberis*, Br. Add., is the stem of *Berberis aristata*, DC., a plant of Northern India.

Lycium, or *Lycium* of the ancients, highly valued as a local application in affections of the eye and eyelids, and used for various other purposes, is supposed to be the medicine still used in India for the same affections, under the name of *rusot* or *ruscut*. According to Royle, extracts from various species of berberis enter into this substance, which, combined with opium and alum, is much used in *ophthalmia*; also in the treatment of *intermittent*, *remittent*, and *typhoid fevers*, *diarrhœa*, and *dyspepsia*. (*P. J.*, Dec. 1865.) Concentrated solution of berberis (*Liquor Berberidis Concentratus*, Br. Add.) may be given in doses of one-half to one fluidrachm (1.8–3.75 Cc.); the *tincture* (*Tinctura Berberidis*, Br. Add., 120 gr. in a pint of 60 per cent. alcohol), in doses of half to one fluidrachm (1.8–3.75 Cc.). *Fluid-extractum Berberidis* is official (see page 529).

Barberry. *Berberis vulgaris*. *Epinevinette*, *Vinetier*, *Ecorce de Racine de Berberides*, Fr. *Fauerach*, *Gemeiner Sauerdorn*, *Berberitze*, *Berberitzen-* (*Saurach*.) *Wurzelrinde*, G. *Berbero*, It., Sp.—This is a native of Europe, but grows wild in waste grounds in the eastern parts of New England, and is sometimes cultivated in gardens on account of its berries. It is a spreading shrub, from four to six feet or more in height, with thorny branches, a light gray bark, and a fine yellow wood. Under the name of *Berberis canadensis*, Pursh described an American plant, which grows in hilly districts, from the borders of

Canada to the Carolinas, and which is characterized, according to Gray, by its repandly-toothed leaves, with the teeth less bristly-pointed, by its few-flowered racemes, its petals notched at the apex, and its oval berries. By Hooker, however, it is considered a variety of *B. vulgaris*, from which it differs only in the points mentioned. By Regel it is referred to *B. sinensis*, Desf., of China. It is from one to three feet high.

The berries of *B. vulgaris*, which grow in loose bunches, are oblong and of a red color, have a grateful, sour, astringent taste, and contain malic and citric acids. They are refrigerant, astringent, and antiscorbutic, and are used in Europe, in the form of drink, in *febrile diseases* and *diarrhœas*. An agreeable syrup is prepared from the juice, and the berries are sometimes preserved for the table. Graeger found in the ripe fruit, freed from stalks, 15.58 per cent. of integuments and seeds, 17.20 of soluble solid constituents, and 67.22 of water. The constituents of the juice in 100 parts of fresh berries were 5.92 parts of malic acid, 4.67 of sugar, 6.61 of gum, 67.16 of water, and 0.06 of salts of potassium and calcium. (*A. J. P.*, Jan. 1, 1873, 14.) The root and inner bark have been used for dyeing yellow. The bark of the root is grayish on the outside, yellow within, very bitter, and stains the saliva when chewed. Brandes found in 100 parts of the root 6.63 of bitter, yellow extractive (impure berberine), 1.55 of brown coloring matter, 0.35 of gum, 0.20 of starch, 0.10 of cerin, 0.07 of stearin, 0.03 of chlorophyll, 0.55 of a sub-resin, 55.40 of lignin, and 35.00 of water.

Hesse found in berberis root four alkaloids besides *berberine*; the mother liquor from berberine hydrochloride when precipitated with sodium hydroxide yielded to ether three alkaloids, a fourth, which is amorphous, remaining undissolved. One of the alkaloids in the ethereal solution crystallized from alcohol in small tabular crystals, and is named by the author *berbamine*. It has the composition $\text{C}_{18}\text{H}_{19}\text{NO}_3 + 2\text{H}_2\text{O}$. (*Ber. d. Chem. Ges.*, 19, 3190.) To a second alkaloid the name of *oxyacanthine* has been applied. It can be obtained from the mother liquor from which the berberine hydrochloride has been separated. The liquid is treated with sodium hydroxide, when a dark colored precipitate is thrown down, from which ether dissolves oxyacanthine, berbamine, and an unnamed alkaloid, while another brown colored amorphous base remains undissolved. The ethereal solution is treated with acetic acid, and the resultant acetate decomposed by sodium sulphate, when oxyacanthine sulphate is precipitated, berbamine remaining in solution. On decomposing the solution of oxyacanthine sulphate with ammonia the free alkaloid is precipitated in flocks, which, after drying at 100°C . (212°F .), melt at from 138° to 150°C . (280.4° to 302°F .), but when crystallized from alcohol or ether it forms anhydrous needles, melting at from 208° to 210°C . (406.4° to 410°F .). Its formula is given as $\text{C}_{19}\text{H}_{21}\text{NO}_3$. It is readily soluble in chloroform and benzene, but only sparingly in petroleum spirit. (*Allen, Com. Org. Anal.*, 2d ed., vol. iii., part 2, 466.) Schmidt and Schilbach have made some interesting studies upon the salts and decomposition products of berberine. (*See A. Pharm.*, 1887, 141; *J. Chem. S.*, 1892, 641.)

Barberry is in small doses tonic, in larger ones cathartic, and was formerly given in *jaundice*. It is a gentle tonic and laxative. It may be used in the form of decoction. For uses of *B. aquifolium*, see *Berberis*, page 236.

The alkaloid berberine is probably a simple bitter tonic, although antiperiodic properties have been attributed to it, and T. Lascarato (*La Grèce médicale*, 1899, No. 2) affirms that it has a specific action upon the spleen which renders it very valuable in the treatment of malarial splenic enlargement, and that it is so powerful in producing contraction that when the spleen is softened large doses may produce splenic rupture, with fatal hemorrhage. Dose, three to five grains (0.2-0.3 Gm.).

Beta-Naphtholsulphonic Acid. *Acidum Betanaphtholinsulphonicum*. $C_{10}H_6(OH).SO_3H$.—*Betanaphtholinsulphonic acid* occurs in white pearly scales, tinged with red. It is readily soluble in water and alcohol, and appears to be interesting to the physician only as a test for albumin in the urine. According to E. Riegler, the reaction is so delicate that it will make plainly visible the presence of one part of albumin in forty thousand of water. Albumoses and peptones are also thrown down, but such precipitates disappear on the application of heat, which does not occur with albumin. Riegler's test is best performed by adding to five or six cubic centimeters of the urine from twenty to thirty drops of a 5 per cent. aqueous solution of the reagent.

Betaine.—This is an alkaloid of weak basic properties which Scheibler discovered in the juice of the sugar beet. (*A. J. P.*, xli. 559.) Husemann showed it to be identical with *lycine*, and to have the composition $C_5H_{11}NO_2$. (*A. J. P.*, 1875, 209.) Liebreich also obtained it by the oxidation of choline, and called it *oxyneurine*. (*Ber. d. Chem. Ges.*, iv. 735.) It has been made synthetically, and its relation to choline and similar compounds established. It is now known to be tri-

Waller and Plimmer (*P. J.*, lxxi. 517) find that betaine is feebly but distinctly toxic. In dose of 0.1 Gm. per kilo it produced in rabbits fall of blood pressure with final paralysis of the heart. They assert that pure betaine is less poisonous than the commercial. They obtained 4.4 Gm. from 1000 Gm. of beet sugar.

Betel. *Br. Add.*—"The leaves of *Piper Betle*, L." *Betle*. (*Chavica Betle* (L.), Miq.)—The betel pepper is largely cultivated in the hotter parts of India, Ceylon, and the Malay Islands, with irrigation and training of the vine upon trees in a manner similar to the Italian cultivation of the grape. The leaves, which are about five inches long, are sometimes gathered green and ripened artificially, those which die upon the vines being of less value. They are described as broadly ovate, acuminate, obliquely cordate at the base, five- or seven-nerved; coriaceous and glossy on the upper surface; they have a warm aromatic bitter taste. As found in commerce they are frequently tied up or stitched together into packets. The warm aromatic taste of the betel leaves is due to an essential oil known as *betel oil*. This is of a color varying from clear yellow to dark brown and of aromatic, somewhat creosote-like, odor and burning sharp taste. The specific gravity ranges from 0.958 to 1.044, the lighter oil being that obtained from the fresh leaves. The alcoholic solution of the oil gives a greenish to bluish-green color with ferric chloride.

The betel oil from Siam contains *cadinene* and a characteristic phenol named *betelphenol*, iso-

meric with eugenol; the oil from Java contains in addition to the betelphenol, *chavicol* and a *sesquiterpene*; while the Manila oil contains betelphenol as the sole phenolic constituent (Gildemeister and Hoffmann, *Die Ätherische Öle*, Berlin, 1899).

The essential oil of betel is an active local stimulant and has been used in doses of one to two minims (0.06 to 0.12 Cc.) in the treatment of various respiratory catarrhs, and as a local application, either by gargle or inhalation, in *diphtheria*. It is said that the juice of four leaves is equivalent in power to one drop of the oil. In India betel leaves are used locally to a considerable extent for the purpose of counter-irritation and applied to the mammary glands for the suppression of the milk.

Betol. *Naphthol. Naphthosolol. Salinaphthol. Salicylic-naphthyl ester. Salicylate of β-naphthol.* $C_6H_4OH.COOC_{10}H_7$.—Betol occurs in white, shining crystals, is odorless and tasteless, melts at 95° C. (203° F.), and is insoluble in cold or hot water, soluble in cold alcohol with difficulty, but readily dissolves in hot alcohol (1 in 3), in ether, and in benzene. It is not decomposed by acids or alkalis in the cold, but the alkaline pancreatic fluid has the power to decompose it into β-naphthol and salicylic acid.

Betol was proposed by Sahli as a substitute for salol, on the ground of its being less disagreeable and yielding in the intestines naphthol instead of the more poisonous phenol. It contains, however, 10 per cent. less salicylic acid than does salol, and, having a much higher melting point, splits up much less readily in the intestines; a fact which gains importance from the observation that frequently salicylic acid cannot be found in the urine after its ingestion. Sahli has given as much as one hundred and eighty grains (11.6 Gm.) in twenty-four hours. Betol may be used in *rheumatism*, and is especially commended by Kobert in *ammoniacal cystitis*. Butter of cacao will dissolve one-fourth of its weight of betol, so that suppositories or bougies are readily made. Dose, ten to twenty grains (0.65-1.3 Gm.).

The *salicylic ester of α-naphthol*, an isomer of betol, is known as *alphanol*. It is said to resemble salol in therapeutic effect. The dose is from eight to thirty grains (0.5-2 Gm.).

Betonica. *Betonica officinalis*, L. *Wood Betony*.—A perennial European labiate herb, feebly aromatic and astringent. Its root has been considered emetic and purgative.

Betula. *Betula alba*, L. *Common European Birch. Bouleau*, Fr. *Birke*, G. (Fam. Cupuliferæ or Betulacæ).—Various parts of this tree have been applied to medicinal uses. The young shoots and leaves secrete a resinous substance, having acid properties, which, combined with alkalis, is said to produce the effects of a tonic laxative. (*J. P. C.*, xxvi. 208.) The *inner bark*, which is bitterish and astringent, has been employed in *intermittent fever*. The epidermis is separable into thin layers, which may be employed as a substitute for oiled paper, and applied to various economical uses. The bark contains *betulin*, or *betula camphor*, which Hausemann (*Ann. Ch. Ph.*, 182, 368) has shown to be a diatomic alcohol, as it forms a diacetate. Its formula is $C_{30}H_{60}O_9$, fusing point 258° C. (496.4° F.). When oxidized it yields *betulinic acid*, $C_{30}H_{54}O_8$, and *betulinamaric acid*, $C_{30}H_{52}O_{10}$. Submitted to dry distillation it yields an oily body of characteristic Russia leather odor. When the bark is distilled, it yields an

emphyreumatic oil, called *Daggett, oleum Rusci, betulinum, or muscoviticum*, it is a thick, brownish-black liquid, sp. gr. 0.955, having the odor of Russia leather, in the preparation of which it is employed. This oil has been found very useful as a local application in *chronic eczema* and other *skin diseases*. Its medicinal properties closely resemble, if they be not identical with, those of oil of cade. Dutch and German oil of birch are quite different from the Russian oil. (See *P. J.*, xv. 769.) The leaves of birch, which have a peculiar aromatic, agreeable odor, and a bitter taste, have been employed, in the form of infusion, in *gout, rheumatism, and dropsy*. Active diuretic properties are claimed for birch leaves and attributed to the *betulorentinic acid* in them. An alcoholic extract has been used in daily doses of from twenty-five to fifty grains (1.6-3.2 Gm.). When the stem of the tree is wounded a saccharine juice flows out which is considered useful in complaints of the kidneys and bladder, and is susceptible, with yeast, of the vinous fermentation. A beer, wine, spirit, and vinegar are prepared from it in some parts of Europe. *Tinctura Rusci* is made, according to Hager, as follows: Ol. Rusci 10, Alcohol, Æther, of each 15, Ol. Lavandule, Ol. Rosmarini, Ol. Rutæ, of each 0.4 parts; filter. (*A. J. P.*, 1881.)

Bezoar.—This name has been given to concretions formed in the stomach or intestines of animals, which were formerly thought to possess extraordinary medicinal virtues. Many varieties have been noticed; but they were all arranged in two classes, the *oriental bezoar (lapis bezoar orientalis)*, and the *western bezoar (lapis bezoar occidentalis)*; the former was most esteemed.

Bichetia. *Bichetia officinalis*. *Murèrè Juice* is extracted in Brazil from the incised bark of this plant; it is a thick reddish liquid, sp. gr. 1.100, and is said to contain an alkaloid and to be useful in *rheumatism and syphilis*. The dose of the juice is one fluidrachm (3.75 Cc.) in water; in large doses it is drastic.

Bicuculla. *Bicuculla canadensis* (Goldie), Millsp. *Corydalis formosa*, Pursh. (*Dicentra canadensis*, Walt.) *Turkey Corn*. *Turkey Pea*. *Squirrel Corn*. (Fam. Papaveraceæ.)—The tubers of this indigenous plant have a slight peculiar odor, and a bitterish somewhat pungent and persistent taste. It is said to yield its active properties to water and alcohol.

According to Merck (*Berichte über das Jahr*, 1892), there are in *Capnoides tuberosum* (DC.), Lyons (*Corydalis cava*, Schweig.), four alkaloids, two of which (*corydaline* and *corycavine*) are weak bases, and two (*bulbocapnine* and *corydine*) strong bases. *Corydaline*, $C_{22}H_{27}NO_4$, is a tertiary base and was obtained crystallized in large prisms, fusing at 135° C. (275° F.), and easily soluble in alcohol and ether. *Corycavine*, $C_{23}H_{23}NO_6$, is difficultly soluble in all solvents, crystallizes in small matted needles, and fuses at 218° C. (424.4° F.), with partial decomposition. *Bulbocapnine*, $C_{15}H_{13}NO_4$, is a crystallizable base, melting at 199° C. (390.2° F.), and soluble in excess of potassium hydroxide. This alkaloid is the one present in largest amount, and was first called *corydaline*; but Merck accepts the name *bulbocapnine*, proposed for it by Freund and Josephy. (*Ber. d. Chem. Ges.*, 25, 2411.) *Corydine* is obtained from the mother liquors of the *bulbocapnine*, and is also a strong base. It is insoluble in water, very readily soluble in alcohol and ether, but cannot be

obtained in crystallized form. J. Gadamer made careful extractions from *bicuculla* bulbs and found about five per cent. of alkaloids. He found the following composition: 1. Crystalline bases: 1, *corydaline*, 2, *bulbocapnine*, 3, *corycavine*, and 4, *corybulbine*. 11. Amorphous mixture of bases consisting of the following, after fractional salt formation: a, crystallizable substances: 1, *corydaline*, 2, *corybulbine*, 3, *isocorybulbine*, 4, *corycavamine*, 5, *corycavine*, 6, *corydine*, 7, *bulbocapnine*, 8, a base melting at 135° C. (275° F.), not identical with *corydaline*; b, two amorphous bases, and *corytuberine*, an alkaloid not extracted by ether, but obtained from the syrupy extract by the addition of a little chloroform. *Capnoides tuberosum*, with its eleven distinct alkaloids, therefore may be compared to *Papaver somniferum* (L.). It is to be noted, however, that *protopine*, which is one of the principal alkaloids in the *Papaveraceæ*, has as yet not been found in *Corydalis cava*. It is possible, however, that *corycavamine*, which has a very similar constitution, takes the place of *protopine* in *corydalis*. The alkaloids of *Corydalis nobilis*, Pers., have been studied by Birsmann. (*A. J. P.*, 1893, 135.) Benzene extracts an amorphous white base of the composition $C_{21}H_{21}NO_6$, resembling the amorphous base (*corydine*?) of *C. tuberosum*. On making the mother liquor alkaline, a brown resinous mass is thrown down, from which benzene separates a base crystallizing from boiling water, with the formula $C_{23}H_{25}NO_5$, to which he gives the name *corydalmobiline*. Several other alkaloids were obtained, and indications of *hydroberberine* and *berberine*.

The tubers of *Bicuculla canadensis* (turkey corn) are asserted to be tonic, diuretic, and alterative, and are given in *syphilitic, scrofulous, and cutaneous affections*, in the dose of from ten to thirty grains (0.65-2.0 Gm.). They are also used in the form of tincture and decoction. *Corydalin* or *corydalia*, of the *eclectics*, is an impure resinous mixture. Fischer and Svell have found that the *Bicuculla cucularia* (L.), Millsp. (*Dicentra cucularia*, Torr.), a plant closely resembling *B. canadensis*, but producing no tubers, contains three alkaloids, one of which is *protopine*. (*Ph. Archiv*, No. 7, 1903.)

Bidens. *Bidens bipinnata*, L. *Spanish Needles*. An indigenous composite plant, of which the root and seeds are popularly used as *emmenagogues*, and by the *eclectics* in *laryngeal and bronchial diseases* as expectorants.

Bignonia.—From the various species of South American bignonias are produced coloring matters which are much used for various purposes by the South American Indians. The most important of these are *carajura*, *chica*, and *ula*. (See *P. J.*, xlv.)

Biodal. *Monoiodo-dibismuthi-methylene-dicresotinate*.—A pink, odorless, insoluble powder, suggested as a substitute for iodoform.

Bird-Lime. *Bird-glue*. *Vogelleim*, G.—A viscid substance, existing in various plants, particularly in the bark of *Viscum album*, L., and *Ilex aquifolium*, L., or *European holly*, from the latter of which it is usually procured. The process for preparing it consists in boiling the middle bark for some hours in water, then separating it from the liquid, and placing it in proper vessels in a cool situation, where it is allowed to remain till it thickens, when it is washed to separate impurities. Bird-lime thus prepared is greenish, tenacious, glutinous, bitterish, and of an odor analogous to that of flaxseed oil. Ex-

posed to the air in thin layers it becomes dry, brown, and pulverizable, but re-acquires its viscosity upon the addition of water. It is a complex body, but is thought to owe its characteristic properties to a proximate principle, which is called *gla* by the French chemists. This principle is without odor or taste, extremely adhesive, fusible by heat, inflammable, insoluble in water, nearly insoluble in alcohol, but dissolved freely by ether and oil of turpentine. According to Macaire, it is insoluble in the fixed oils, either hot or cold, a property which distinguishes it from the resins. Macaire proposed for it the name of *viscin*. (*J. P. C.*, xx. 18.) Its analysis corresponds to the formula $C_{20}H_{48}O_8$ (or possibly $C_{20}H_{32} + 8H_2O$). After the extraction of the viscin by ether, Reinsch found a substance soluble in oil of turpentine which he called *viscouthin*, because of its elastic caoutchouc-like character. He gives it the formula $C_8H_{16}O$. Bird-lime is so tenacious that it may be employed to catch small birds, which, when they alight on a stick thickly covered with it, are unable to escape.

Under the name of *viscum aucuparium verum*, or *viscin*, bird-lime has become a commercial substance which, when dissolved in benzene, gives a syrupy, intensely green solution capable of any degree of concentration, and possesses extraordinary adhesive powers, adapting it for use as the basis of plasters and also as a vehicle for various dermatological remedies. The ordinary base of *viscin plasters*, as proposed by Riehl, consists of a mixture of forty-eight troyounces (1500 Gm.) solution of viscin, three troyounces, one and one-half drachms (100 Gm.) powdered orris, thirteen troyounces (400 Gm.) starch, to which are added Venice turpentine, nine troyounces, three drachms (280 Gm.), and Damar gum, one troyounce (31 Gm.), the whole reduced to a paste by evaporation. In the preparation of salicylic viscin plasters the same formula is followed, excepting that the last two substances are replaced by 5 to 10 per cent. of salicylic acid. Various viscin plasters are made with mercury, iodoform, and other active substances. *Zincum viscosum* is a viscin solution of the consistency of linseed oil, containing 10 per cent. of zinc oxide.

Bismal.—The bismuth salt of methylene-digallic acid. A grayish-brown powder, insoluble in water or the gastric juice, but soluble in alkaline solutions. It is used as an astringent in *diarrhœa*. *Dose*, from one and one-half to five grains (0.096–0.32 Gm.).

Bismone. Colloidal Bismuth Oxide.—A substance said to be produced by the reaction between bismuth salts and alkaline solutions of sodium lysalbinat or protalbinat. It occurs as a translucent amorphous mass, containing 22.3 per cent. of bismuth oxide; freely soluble in warm or cold water, the solution up to 25 per cent. being a reddish-yellow and slightly opalescent tasteless fluid; when stronger, syrupy or gelatinous. It has been highly recommended in the treatment of *gastro-intestinal catarrh*, especially in infants. It cannot be used hypodermically on account of its tendency to produce local disturbances and nephritis. Eighty minims (5 Cc.) of a 10 per cent. aqueous solution may be given three or four times a day to young children, and *doses* of fifteen grains (1 Gm.) are said to be borne without difficulty by older children; always given in solution and not in powder.

Bismutan. Isutan.—A yellow, odorless powder, consisting of bismuth, resorcinol, and tannin.

It is recommended for *intestinal catarrh* in doses for adults of from eight to fifteen grains (0.5–1.0 Gm.).

Bismuth Albuminate. Bismuthi Albuminas. Bismuthum Albuminatum. Wismutalbuminat, G. A compound of indefinite composition made by adding a solution of 75 parts of dried egg-albumin to 25 parts of bismuth and ammonium citrate dissolved in a small quantity of water and drying the product at a low temperature.

A pale gray or white powder, not wholly soluble in water, containing from 10 to 12 per cent. of bismuth. It is used in gastric and intestinal cramps in doses of from eight to fifteen grains (0.5 to 1.0 Gm.).

Bismuth Benzoate. Bismuthi Benzoas. BiO. (C₇H₅O₂).—Basic Bismuth Benzoate is official in the French Codex. It is a white powder, insoluble in water, and was originally proposed by P. Vigier as a substitute for the bismuth salicylate; it may be made by double decomposition between bismuth nitrate and sodium benzoate; like the salicylate, it is decomposed in the alimentary canal, benzoic acid being set free. It contains about 65 per cent. of bismuth, and may be given as an intestinal antiseptic in *diarrhœas*, in doses of from eight to fifteen grains (0.5–1.0 Gm.) four to six times a day. The benzoate has been commended by Finger as a substitute for iodoform.

It may be made by adding a solution (prepared with heat) of 76 parts of sodium benzoate in 200 parts of distilled water to a solution of 100 parts of bismuth nitrate in 20 parts of glycerin and 60 parts of distilled water. It contains 27 per cent. of benzoic acid.

Bismuth Borate.—*Bismuthi Boras*, $BiBO_3$, is a grayish-white powder which has been used as an intestinal antiseptic in doses of from seven to fifteen grains (0.45–1.0 Gm.).

Bismuth Borophenate.—*Bismuthi Borophenas, Markasol*, has been recommended as a slightly astringent absorbent powder, to be used in the same way and for the same purposes as iodoform. It is free from odor, and is alleged to be locally antiseptic.

Bismuth-Cerium Salicylate is a reddish-white powder, insoluble in water and alcohol. This salt has been highly commended in *diarrhœa*, *enteritis*, and *dysentery* by Salaya. *Dose*, ten grains (0.65 Gm.).

Bismuth Chrysophanate. Bismuthi Chrysophanas. Dermol. Bismuthum Chrysophanicum. $Bi(C_{15}H_9O_4)_3.Bi_2O_3$.—This is a yellow, amorphous, insoluble powder, which has been used in the treatment of various diseases of the skin.

Bismuth Dithiosalicylate. Bismuthi Dithiosalicylas. Thioform. $(S.C_6H_3(OH)COO.BiO)_2.Bi_2O_3 + 2H_2O$.—This is a yellowish-gray, odorless and tasteless powder, insoluble in water, alcohol, or ether. It has been used externally as a dusting powder in skin diseases and in surgery, and probably acts precisely as does dermatol. It has been employed upon the eye to a considerable extent and is not irritant. Internally it has been given in *diarrhœa* as an intestinal antiseptic in doses of five grains (0.32 Gm.) three or four times a day in capsules.

Bismuth Iodo-oxyquinoline-sulphonate. Bismuthi Loretinus. Loretin Bismuth.—This compound has been used in the dose of four-fifths of a grain (0.05 Gm.) every four hours in the treatment of tubercular and other obstinate *diarrhœas*, and as a local application in powder form to *epithelioma*, *syphilitic* and other forms of infected

ulcers. The 10 per cent. ointment made with lanolin has been recommended in eczema and psoriasis.

Bismuth Lactate. *Bismuthi Lactas*.—This salt may be made as follows. Take of bismuth subnitrate, *sixty-one parts*; ammonia water, *fifty parts*; lactic acid, *fifty-five parts*; distilled water, *a sufficient quantity*. Mix the bismuth subnitrate, in a flask, with the ammonia water previously diluted with *seventy-five parts* of distilled water. Let the mixture stand for one hour, pour off the supernatant liquid, and wash the residue thoroughly with distilled water. To the moist residue add the lactic acid, and evaporate the mixture to dryness on the water bath. The product is a white powder, slowly soluble in water and insoluble in alcohol. It may be used in diarrhoea in doses of one to two grains (0.065–0.13 Gm.).

Bismuth Metacresolate. *Bismuthi metacresolatus*.—A pale gray or white powder, odorless and tasteless, insoluble in water and alcohol. It is used as an internal antiseptic and also as an antiseptic dusting-powder, to take the place of iodoform.

Bismuth Naphtholate. *Naphthol Bismuth. Betanaphthol Bismuth. Orphol.* $(C_{10}H_7O)_2Bi + 3H_2O$. (Merck.)—This is a neutral, light brown, almost odorless and tasteless non-irritant powder, insoluble in water, which, according to its manufacture, contains 80 per cent. of bismuth in combination with 20 per cent. of betanaphthol. According to F. A. Jasenski it is broken up both in the stomach and in the intestines into its constituents, which are to a slight extent absorbed, but to a much greater extent act locally as a gastro-intestinal antiseptic; useful in *acute and chronic enteritis*, in *fermentative diarrhoeas*, in various forms of *dyspepsia*, and whenever an intestinal antiseptic is desired. The drug has also been used locally in *gonorrhoea*, external *ulcerations*, *impetigo*, etc. It is affirmed, however, to be harmless, and Chaumier states that he has frequently given seventy-five grains a day to young children with impunity. It is probable that only a small portion of these large doses is decomposed in the gastro-intestinal tract, the greater part passing out unchanged. The ordinary dose is from eight to fifteen grains (0.5–1.0 Gm.) in capsule or suspended in water.

Bismuth Oleate. *Bismuthi Oleas*. $Bi(C_{17}H_{33}CO_2)_3$.—A compound resulting from the reaction between sodium oleate and bismuth trinitrate. It forms an insoluble powder and is used as an emollient and astringent.

Bismuth Oxybromide. *Bismuthi Oxybromidum. Wismutoxybromid.* $G. BiOBr$.—This is an impalpable yellow powder, used internally in gastric affections.

Bismuth Oxychloride. *Bismuthi Oxychloridum seu Subchloridum. Bismuth Subchloride. Bismuthyl Chloride. Oxychlorure de bismuth.* $Fr. Wismutoxychlorid, G. BiOCl$.—Made by slowly pouring a solution of bismuth trinitrate, in diluted nitric acid, into a solution of sodium chloride, collecting the white precipitate, washing and drying. It is sometimes known as *pearl white*, and in France as *blanc de fard*. Bismuth oxychloride is insoluble in water, soluble in acids, and is used for the same purposes as bismuth subnitrate.

Bismuth Oxyiodide. *Bismuthi Oxyiodidum. BiOI*.—This compound, sometimes termed *Bismuthi Subiodidum*, may be made by F. X. Moerk's process, as follows: Take of iodine, 4.6

Gm.; bismuth subnitrate, 10 Gm.; nitric acid, sp. gr. 1.42, 10 Cc.; solution of sodium hydroxide, U. S. P., 150 Cc.; water, a sufficient quantity. The iodine is covered with 50 Cc. of water, and converted into hydriodic acid by passing hydrogen sulphide through the mixture, boiling to remove excess of hydrogen sulphide, and filtering. The subnitrate is dissolved in the nitric acid, diluted with 10 Cc. of water, and then enough water added to produce a slight permanent opalescence; this mixture is then slowly poured into the solution of sodium hydroxide with constant stirring. The precipitate is then washed by decantation until the washings cease to turn red litmus paper blue; 50 Cc. of water are added to it, and the hydriodic acid gradually poured in, until after stirring and allowing to settle the supernatant liquid has a yellow color. The oxyiodide is washed by decantation, removed to a filter, allowed to drain, and, finally, dried at a temperature not exceeding 100° C. (212° F.). The oxyiodide has a light yellowish-red color, and contains no water of crystallization. (A. J. P., 1887, 273.) In 1877 the bismuth oxyiodide was recommended as a local antiseptic and substitute for iodoform, by A. Sidney Reynolds. It has been used to a considerable extent with success in the Philadelphia Hospital, but its high price interferes with its general adoption. It has also been given internally in *gastric ulcer* and other gastric affections for which bismuth is usually employed. The dose is from five to ten grains (0.32–0.65 Gm.).

Bismuth Oxyiodo-methyl-gallol. *Bismuthi Oxyiodo-methylgallolum. Iodo-gallicin.* $C_6H_2COOCH_2(OH)_2O.BiO.HI$.—Made by acting upon gallicin (methyl gallate) with bismuth oxyiodide. It is in the form of a light, amorphous, dark gray powder, insoluble in ordinary solvents and containing 23.6 per cent. of iodine and 38.4 per cent. of bismuth.

It is used as an antiseptic powder to replace iodoform.

Bismuth Oxyiodo-pyrogallate. *Bismuthi Oxyiodo-pyrogallas.* $C_6H_2(OH)_2O.Bi(OH)_2I$.—Made by digesting bismuth oxyiodide with pyrogallic acid or by precipitating a solution of potassium iodide and pyrogallic acid with bismuth nitrate in acetic acid. A fine, amorphous, yellowish-red powder, permanent in light and air. It is recommended as a powerful surgical antiseptic powder.

Bismuth Oxyiodo-tannate. *Bismuthi Oxyiodo-tannas.*

Bismuth oxyiodo-tannate is a greenish-gray, odorless, tasteless powder, becoming brownish on exposure, insoluble in water, and has been suggested as a surgical substitute for iodol.

Bismuth Peptonate. *Bismuthi Peptonas*.—Prepared by adding a solution of 80 parts of dried peptone to 20 parts of bismuth and ammonium citrate, dissolved in a small quantity of water, and drying at a low temperature. A grayish-brown powder containing from 7 to 8 per cent. of bismuth.

It is used in *dyspepsia* and *gastralgia* in doses of from fifteen to sixty grains (1.0–3.9 Gm.).

Bismuth Phenolate. *Bismuthi Phenolas. Bismuth Carbolate. Phenol-Wismut.* $G. C_6H_5O.Bi$

(OH)₂.—Made by a reaction between solutions of bismuth trinitrate and sodium phenolate. A gray, insoluble, inodorous powder, used as an internal antiseptic, in doses of from eight to fifteen grains (0.5–1.0 Gm.), also as an antiseptic dusting-powder.

Bismuth Phosphate, Soluble.—*Bismuthi Phosphas Solubilis*, which is prepared by the melting together of bismuth, sodium hydroxide, and phosphoric acid, is a powder easily soluble in water, precipitated by alkalis, acids, or heat, and undergoing spontaneous decomposition when in concentrated solution. It contains 20 per cent. of bismuth, and has been used as an intestinal antiseptic in *choleraic* and other acute *diarrhœas* in the dose of from three to eight grains (0.2–0.5 Gm.) three times a day.

Bismuth Pyrogallate. *Bismuthi Pyrogallas. Helcosol.* $C_6H_3(OH)_2OBiO$.—It is a yellowish-green amorphous powder, insoluble in water and alcohol, soluble in acid and alkaline solutions and in the gastro-intestinal juices. According to von Heyden, it contains about 60 per cent. of bismuth. In very large doses it is said to be non-poisonous, and to be a valuable intestinal antiseptic; if, however, pyrogallic acid should be liberated in the alimentary canal, it might produce disagreeable effects, and the remedy seems to us dangerous.

Bismuth Resorcinate. *Bismuthi Resorcinas. Resorcin-Wismut.* G. $[C_6H_3(OH)_2Bi_2O_3 + Bi_2O_3]$. Prepared by adding a solution of bismuth trinitrate to a solution of resorcinol in an excess of alkali. A yellowish-brown powder containing about 40 per cent. of Bi_2O_3 . It is used in chronic and acute catarrh of the stomach.

Bismuth Sulphite.—*Bismuthi Sulphis*, $Bi_2(SO_3)_3$, is made by reacting on normal bismuth nitrate with sodium sulphite. It is an antiseptic and antiferment with anthelmintic properties.

Bismuth Tannate. *Bismuthi Tannas*.—Bismuth tannate has been used as an astringent in *diarrhœas* in doses of from ten to thirty grains (0.65–2.0 Gm.).

Bismuth Valerate. *Bismuthi Valeras. Valérianate de Bismuth.* Fr. *Wismutvalerianat.* G. $Bi(C_8H_7O_2)_3$.—This salt is formed by double decomposition between solutions of bismuth trinitrate and sodium valerate. Bismuth valerate precipitates as a white powder, which is washed with water, and dried with a gentle heat. It has been recommended by Righini in *neuralgia*, and in *gastrodynia*. The dose is from half a grain to two grains (0.032–0.13 Gm.), repeated several times a day, and given in the form of pill.

Bismuthol. *Bismutal*.—This substance, which is probably a mere mixture of the bismuth phosphate and the sodium salicylate, is a white, crystalline, odorless powder, soluble in water, which has been commended by Radlauer as an antiseptic in the treatment of wounds and inflammations of the mucous membrane. It may be used with talc (from 1 to 2 to 1 to 5) as a powder, or in a 10 to 20 per cent. ointment with vaseline, or as a 1 to 4 per cent. aqueous solution, in the treatment of *infected wounds*, *syphilitic* and other *ulcers*, and as an injection in *gonorrhœa*, chronic *sinuses*, etc. It has been especially recommended for excessive sweating of the feet.

Bismutose.—This substance is said to be an albuminous compound containing 22 per cent. of bismuth, 66 per cent. of albumin and impurities. It is a tasteless white powder which gradually acquires under the influence of light a slaty-gray color. It is insoluble in water and other solvents,

and dilute acids partly dissolve it when warmed. With dilute alkaline solution it forms rapidly, especially when heated, an opalescent fluid. It is affirmed to be non-poisonous. It has been highly praised by Laquer (*Ther. Geg.*, July, 1901) as a remedy specially for children in all those forms of *gastric* and *intestinal irritation* or *ulceration* for which bismuth has been employed. The dose for infants is 15 to 30 grains (1–2 Gm.), for children a drachm (3.9 Gm.), and for adults larger quantities. It is also employed as a dusting-powder in the treatment of *burns* and *intertrigo* as an absorbent.

Bistort. *Snakeweed. Bistorte, Couleuvreine.* Fr. *Weissenknöterich, Natterwurze*, G.—This is the root of *Polygonum Bistorta*, L. (Fam. Polygonaceæ), a perennial herbaceous plant, growing in Europe and the north of Asia. The root is cylindrical, somewhat flattened, about as thick as the little finger, marked with annular or transverse wrinkles, furnished with numerous fibres, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. When dried, it is solid, brittle, of a deep brown color externally, reddish within, inodorless, and of a rough, astringent taste. It contains much tannin, some gallic acid and gum, and a large proportion of starch. H. K. Bowman found 21 per cent. of tannin in bistort root. (A. J. P., 1869, 193.) Its medicinal properties are like those of kino, but it is less efficient. It may be employed in powder, decoction, or extract. The dose of the powder is twenty or thirty grains (1.3–2.0 Gm.).

Besides the bistort, some other plants belonging to the genus *Polygonum* have been used as medicines. Among these are *P. aviculare*, L., or *knot grass*, a mild astringent, formerly employed as a vulnerary and styptic; *P. Persicaria*, L. (*Persicaria mitis*, Gilib.), of a feebly astringent saline taste, and at one time considered antiseptic; and *P. hydropiper*, L., or water-pepper (*Persicaria hydropiper*, Opiz.), the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic, and have been used with asserted success in *amenorrhœa* and other *uterine disorders*. Its irritant and also medicinal properties are due to an acid, *polygonic acid*, discovered by C. J. Rademaker. (A. J. P., xlii. 490.) The water-pepper or smartweed of this country—*P. punctatum*, Ell.—which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as a detergent in chronic *ulcers*, and internally in *gravel*. B. Woodward found that the dried plant contains 18 per cent. of tannin, and used a saturated tincture with great advantage in *diarrhœa* and *dysentery*, in doses of from twenty to sixty minims (1.3–3.75 Cc.). Aughey finds that *P. amphibium*, L., is readily cultivated, with a yield of from three to six tons to the acre, that the roots contain 21.75 per cent., the stems 17.1 per cent. of tannic acid, and urges the growth of it for tanning purposes. (N. R., 1876, 75.) *P. Fagopyrum*, L., is common buckwheat. The leaves of this plant have been found by Ed. Schunck to contain a crystallizable coloring principle, identical with the *rutin* or *rutic acid* previously discovered by Weiss in the leaves of the common rue, and probably, with the *liwanthin* of Moldenhaus, existing in the leaves of *Ilex aquifolium*, L., or the common holly. Buckwheat leaves yielded to Schunck somewhat more than one part of rutin in a thousand.

(*Chem. Gaz.*, No. 399, 201.) From *P. cuspidatum*, L., has been separated a glucoside, *polygonin*, and also *emodin*. (*P. J.*, Feb. 1896.)

Various species of the genus *Polygonum* are used for the production of dye-stuffs; thus, indigo is obtained largely in China, Japan, and in some parts of Russia, from the leaves of *P. tinctorium*, Ait., and is said also to be yielded by those of *P. aviculare* and *P. barbatum*, L.; while in India, China, and Japan the roots of the *P. cuspidatum* are employed for making a yellow dye. (*J. Chem. S.*, Dec. 1895.)

Blennostasine.—W. F. Chappell (*N. Y. M. J.*, lxiv. 1896) asserted that this derivative of a cinchona bark alkaloid is a powerful sedative to the brain and spinal cord, and that in doses of from one to four grains (0.065–0.26 Gm.) every hour it is a valuable remedy in nasal and laryngeal hyperæsthesia.

Blepharis. *Blepharis capensis*.—This plant is said to be physiologically very active and useful in the treatment of *anthrax*. (*P. J.*, 60, p. 140.)

Blood of Bullocks.—As long ago as 1852 Samuel Jackson of Philadelphia, employed as a tonic the blood of bullocks carefully dried *in vacuo*, giving from five to ten grains (0.32–0.65 Gm.) of it as a dose. Recently it has been used considerably in Europe, and even drinking fresh bullock's blood was at one time in fashion. Under the name of *Sanguis Bovinus Essiccatus*, F. E. Stewart introduced defibrinated dried bullock's blood, claiming for it that, by the simple addition of water, bullock's blood can be reproduced minus a small quantity of fibrin. There is no reason for believing that dried blood is more valuable than the more usual ferruginous tonics, if indeed it be of equal value.

Blumea. *Blumea lacera*, DC. (*Fam. Compositæ*).—From this plant, which is used in India as an insect powder, Dymock has obtained a light yellow volatile oil. It has a sp. gr. of 0.9144 at 26.7° C. (80° F.), and an extraordinary rotating power, 1 Mm. turning the ray 66° to the left.

Bocconia.—It is probable that various species of this papaveraceous genus have active medicinal properties. *B. arborea*, Watson, of Mexico, has been found by Elliott to contain two alkaloids, one of which is probably *sanguinarine*; and the leaves of other species are used in South America as abortifacients, purgatives, etc. (See Rusby, *Bull. Pharm.*, 1891.)

Boldo. *Boldus*.—This plant is an evergreen shrub, frequenting the meadows of the Andes in Chili, where its yellowish-green fruit is eaten, its bark used in tanning, and its wood in charcoal making. It is the *Peumus Boldus* of Molina (1782); *Peumus fragrans*, Pers.; *Boleia fragrans*, C. Gay, also Juss.; *Ruizia fragrans*, Pav. (*Fam. Monimiaceæ*.) The leaves, which are the parts used in medicine, contain in special cells an aromatic volatile oil, of which they yield, on distillation, about 2 per cent. They are entire, reddish brown when dry, coriaceous, with a prominent midrib and very numerous small glands upon their surface. The oil boils between 175° and 250° C. (347° and 482° F.) and gives a green coloration with ferric chloride, it contains terpene and oxygenated bodies which have not as yet been investigated. A peculiar alkaloid, *boldine*, has been found in them by Bourgoin and Verne (*J. P. O.*, 4e sér., xvi. 191), and a glucoside, *boldoglucin*, $C_{30}H_{52}O_8$, by P. Chapoteaut. (*C. R. A. S.*, xlviii. 1052.) According to Sigismund Pascaletti (*Therapia Moderna*, 1891), boldine when

injected hypodermically paralyzes both the motor and sensory nerves, and also attacks the muscle fibres. As a local anæsthetic he believed it to be superior to caffeine but inferior to cocaine. When given internally in toxic dose it produces great excitement, with exaggeration of the reflexes and of the respiratory movements, increased diuresis, cramps, disorder of coördination, convulsions, and finally death from centric respiratory paralysis, the heart continuing to beat long after the arrest of respiration, finally stopping in diastole. Boldoglucin is said to act on the lower animals as a narcotic, and has been given by René Juranviller, with asserted success, as a hypnotic and calmative remedy in *insanity*. Fifteen minims (0.9 Cc.) of the oil of boldo cause in man some warmth in the epigastrium; thirty minims (1.8 Cc.), much gastric irritation, with pain and vomiting, and passage of urine smelling strongly of the oil. Dujardin-Beaumetz finds the oil useful in *genito-urinary inflammations* in doses of five drops (0.25 Cc.) (*B. G. T.*, Mars, 1875), in diseases of which character the drug has long been employed in South America. (*Ibid.*, lxxvi. 165.) In France boldo has been employed as a tonic in *chronic hepatic torpor* and in *hepatitis*. (*Etude sur le Boldo*, C. Verne, Paris, 1883.) Eight minims (0.5 Cc.) of a tincture (1:5) or four minims (0.25 Cc.) of a fluidextract may be considered as the commencing dose, increased *pro re nata*. Large doses are apt to vomit and purge.

According to A. T. De Rochebrune (*Toxicol. Africaine*, i. 1897), the tree *Monimia rotundifolia* of Australia, contains an abundant volatile oil, an alkaloid, and a glucoside, which are very similar to, if they be not identical with, those obtained from the *Boldo*, and may be substituted for the latter in therapeutics.

Bole Armenian. *Bolus Armeniæ*. *Bolus Rubra*. *Argilla Ferruginea*.—The term *bolus* or *bole* was formerly applied to various forms of argillaceous earth, differing in color or in place of origin. Such were the *Armenian*, *Lemnian*, and *French boles*, and the *red* and *white boles*. Some of these substances were so highly valued as to be formed into small masses and impressed with a seal, and hence received the name of *terre sigillatæ*. They were all similar in effect, though the small proportion of oxide of iron contained in the colored boles may have given them greater activity. The only one at present kept in the shops is that called *bole Armenian*, from its resemblance to the substance originally brought from Armenia. It is prepared, by trituration and elutriation, from certain native earths existing in different parts of Europe. It is in pieces of various sizes, reddish, soft, and unctuous, adhesive to the tongue, and capable of forming a paste with water. It consists chiefly of a hydrated aluminum silicate with ferric hydrate. The boles were formerly employed as absorbents and astringents in *acidity of the stomach* and in *relaxed bowels*. Bole Armenian is used chiefly as a coloring ingredient in tooth-powders.

Bonduc Seeds.—These are seeds derived from several species of the genus *Cæsalpinia*, called also *Guilandina* (*Fam. Leguminosæ*), which are used in India as febrifuges, tonics, and antiperiodics. Heckel and Schlagdenhauffen have discovered in them a bitter principle (*C. R. A. S.*, 103, 89), probably identical with that previously isolated by Flückiger. (*Pharmacographia*, 2d ed., 212.)

Bone. *Os*, Lat., Fr. *Knochen-Asche*, G. *Ossa*, It. *Huesos*, Sp.—Under the name of *Os Ustum*, or *Bone ash*, the Br. Pharmacopoeia formerly recognized "the residue of Bones, which have been burned to a white ash in contact with air. Bone ash consists principally of phosphate of calcium, mixed with about 10 per cent. of carbonate of calcium and a little calcium fluoride, silica, and magnesium phosphate." When bones are subjected to destructive distillation, in close vessels, they are decomposed without alteration of shape, lose about three-sevenths of their weight, become brittle, and are converted into a black substance, containing the earthy salts of the bone, and constituting the species of animal charcoal called *bone black*. (See *Carbo Animalis*.) The portions which distil over consist of the usual ammoniacal products derived from animal matter, but are especially rich in nitrogenous bases of the pyridine and quinoline series. (See *Ammonii Chloridum*.) Before the distillation is performed, the bones are boiled with water, to separate the fat, which amounts to 5 or 6 per cent.; but gelatin is at the same time extracted, with the effect of rendering the bones less fitted to furnish a good bone black. In view of this fact, M. Deiss of Paris, has proposed to extract the fat by carbon disulphide, which gives a product of 10 or 12 per cent., without injuring the bones for subsequent conversion into bone black. (*A. J. P.*, 1856, 356.)

When calcined in open vessels, bones are converted into a white friable substance, consisting of the incombustible part, and commonly called *bone earth*, or *bone ash*; and a similar residue is obtained by calcining horns, and is termed *Cornu Ustum*. When bones are treated with boiling water, a small portion of the gelatinous matter is dissolved; but when acted on by water in a Papin's digester, the whole of it is taken up and the earthy salts, deprived of their cement, crumble into powder, and become diffused through the solution. When acted on by diluted hydrochloric acid, the earthy salts are dissolved, and the bone softens without losing its shape and becomes semi-transparent and flexible. The portion remaining unattacked by the acid is the gelatinous tissue, which may be converted into gelatin by long boiling. The hoof bones of the ox, boiled with water, furnish a peculiar oil, called *neat's-foot oil*.

The bones of different animals, and of the same animal at different ages, vary somewhat in composition. Dry ox bones consist of bone gelatin (cartilage of bone) 33.3, calcium bone phosphate with a little calcium fluoride 57.35, calcium carbonate 3.85, magnesium phosphate 2.05, and sodium hydroxide with a very little sodium chloride 3.45 = 100. Human bones differ somewhat in the proportions of their constituents, and in containing traces of iron and manganese. According to W. Heintz, however, bones exhausted by water, so as to remove the coloring matter of blood do not contain a trace of iron. Marchand found 1 per cent. of calcium fluoride in human bone. *Calcium bone phosphate* consists of the tribasic phosphate, $\text{Ca}_3(\text{PO}_4)_2$.

Borago. *Borago officinalis*, L. *Borage*. *Bour-rache*, Fr. *Borasch*, *Boretsch*, G. (Fam. Boraginaceæ).—This European annual abounds in mucilage, and the stems and leaves contain potassium nitrate with other salts. To these constituents the plant owes its feeble medicinal properties. An infusion of the leaves and flowers is employed as

a demulcent, refrigerant, and gently diaphoretic drink. The expressed juice of the stems and leaves is also given in the dose of from two to four fluidounces (60–120 Cc.).

Boral.—*Aluminum boro-tartrate* is soluble in water, and is used in the form of a fine powder. *Aluminum boro-tannate (cutol)* contains 47 per cent. of tannin. Both salts are used as astringents by dermatologists.

Boricin.—A mixture of sodium borate and boric acid.

Bornyval.—This isovaleric ester of borneol, $\text{C}_{10}\text{H}_{17}\text{O}_2\text{C}_6\text{H}_9\text{O}$, is a limpid fluid with an aromatic odor, suggesting valerian; soluble in alcohol and ether, insoluble in water; boiling under ordinary pressure, at 255° to 260° C. (491° to 500° F.); sp. gr. at 20° C. (68° F.) 0.951. Polariscopic rotation: $[\alpha]_D^{20} = 27^\circ 40'$. It has been urged as a substitute for valerian, given in doses of 4 to 8 grains (0.26–0.5 Gm.) several times a day.

Boro-Citric Acid.—A combination of the two acids, forming a white, very soluble powder. It is used in doses of from five to twenty grains (0.32 to 1.3 Gm.) as a solvent for the urates and phosphates in *urinary calculi and gout*.

Boro-Formol. *Boro-formalin*.—Made by dissolving aluminum hydroxide in a solution of 1 part of boric acid, and 2 parts of formic acid, evaporating and crystallizing. Used as a deodorant and antiseptic.

Boro-Phenol is a combination of borax and phenol. It has an agreeable odor, is completely soluble in water, and can be used for all the purposes for which carbolic acid disinfectants are used.

Boro-Salicylic Acid has been introduced by Cesaris and Carcano as an antiseptic; the solution contains 4 per cent. each of boric and salicylic acids.

Borogen.—This is the ethyl ester of boric acid, $\text{B}(\text{O}_2\text{C}_2\text{H}_5)_3$. It is a liquid, boiling at 120° C. (248° F.), which is decomposed by water into boric acid and alcohol. It is inflammable, burning with a green flame. This substance has been suggested as a local remedy in diseases of the nasal and respiratory mucous membrane, under the belief that it is decomposed into its constituents in the throat and lungs. Borogen is used by inhalation.

Boroglyceride. *Boroglycerinum.* *Glyceryl-borate*.—This substance has been largely employed as a convenient form of obtaining boric acid in a soluble condition. It is made by heating boric acid and glycerin together so as to effect a combination without discoloring the product by overheating. (See *Glyceritum Boroglycerini*, page 592.) James Kennedy (*Nat. Drug.*, 1887, 46) maintained that it is a chemical compound, and not a mere mechanical mixture, as has been supposed; he gave it the formula $\text{C}_3\text{H}_5\text{BO}_3$, and expressed the reaction in its formation thus:

The metallic boroglycerides, such as sodium and calcium boroglyceride, are not explained, however, in this case. Aqueous solutions of boroglyceride are used for preserving milk, meat, fruit juices, etc. Under the name of *glacialin* a substance has been largely sold in England which is simply boroglyceride.

Borol.—This is a compound possessing the structural formula $\text{SO}_2 \begin{smallmatrix} \text{BO} \\ \text{KO} \end{smallmatrix}$ or $\text{SO}_2 \begin{smallmatrix} \text{BO} \\ \text{ONa} \end{smallmatrix}$, or as it may be written, BKSO_4 or BNaSO_4 . It occurs in irregular, colorless, odorless, vitreous

fragments, soluble in five times its weight of water. According to H. Jäger, it is three times as powerful as phenol as an antiseptic, the 2 per cent. solution rapidly destroying most pathogenic germs. It has been used internally in various germ diseases and externally in diphtheria, gonorrhoea, ozena, psoriasis, and other surgical affections. Dose, from thirty to fifty minims (1.8 to 3.1 Cc.) of a 20 per cent. solution well diluted. Locally a 1 to 2 per cent. solution has been used. (*Ther. Woch.*, iv.)

Borsalicyl is made by Bernegau by triturating thirty-two parts of sodium salicylate with twenty-five parts of finely powdered boric acid with a little water; the hardened mass is dried and powdered. It is used as an antiseptic. (*Ap. Ztg.*, 1894, 876.)

Bowdichia. *Bowdichia virgilioides*, H. B. K. (*B. major*, Mart.) (Fam. Leguminosae.)—Under the name of *Sucupira*, the hard, yellow, very bitter bark yielded by this tree is employed in Brazil in fevers and rheumatism. Petit has found in it a mydriatic alkaloid. (*P. J.*, June, 1885.)

Bragantia. *Bragantia Wallichii*. (Fam. Aristolochiaceae.)—The roots of this shrub of India contain an alkaloid allied to aristolochine, a soft resin, a resinous acid, and a substance related to dulcite. (*P. J.*, 1894, 231.)

Brassica.—In China the oil of *Brassica sinensis*, or *petsai*, is used for lighting, and is said also to be purgative, and useful in skin diseases, while the Japanese employ the yellow oil of *B. campestris*, L., under the name of *aburana*, for culinary and lighting purposes. (*A. J. P.*, June, 1885.)

Brazil Nuts. *Cream Nuts.* *Para Nuts.* *Châtaigne du Brésil*, Fr. *Paramuss*, G.—These are edible nuts imported from Brazil, and sometimes employed in making cream syrups for giving flavor to carbonic acid water. In Brazil an expressed oil is obtained from them, which is said to be used for burning, making ointments, and adulterating copaiba. The nuts are the product of *Bertholletia excelsa* (Humboldt and Bonpland), a large and beautiful tree of the fam. Myrtaceae, growing over extensive regions in South America. Corenwinder has found in the kernel of the nut 65.60 per cent. of oil, and 15.31 per cent. of nitrogenous matter. (*P. J.*, Aug. 1873.)

Brazil Wood.—A red dye-wood, the product of different species of *Casalpinia*, growing in the West Indies and South America. Two varieties are known in commerce,—1, the proper Brazil wood, said to be derived from *Casalpinia echinata*, Lam., and sometimes called *Pernambuco* or *Pernambuco wood*, from the province of Brazil, where it is collected; 2, the *brasileto*, produced by *C. brasiliensis*, L., and *C. Crista*, L., which grow in Jamaica and other parts of the West Indies. The former is the most highly valued. The *Nicaragua* or *peach wood* is also analogous to the *brasileto*, and is said by Bancroft to be derived from a species of *Casalpinia*. It is produced in the East Indies. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its coloring matter to water. It was formerly used in medicine, but has been abandoned as inert. In pharmacy it serves to color tinctures, etc., but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink. Its dyeing properties are owing to a crystallizable coloring principle, named *brasilin* or *brasilin*, $C_{16}H_{14}O_5$. This, as usually obtained, is of a sulphur-yellow color, which it preserves in

the dark, but soon loses in the sunlight, to which it is remarkably sensitive, changing to a reddish hue after a few minutes' exposure, and undergoing a similar alteration in diffused daylight, though more slowly. The principle should, therefore, be kept in perfectly opaque vessels. It is now stated that when absolutely pure it is colorless, and becomes red on exposure to the air. The change is due to the formation of *brasilin*, $C_{16}H_{12}O_5$, which can be prepared from the *brasilin* by a variety of methods, such as oxidation by nitrous acid, by alcoholic iodine solution, etc. *Brasilin* is sparingly soluble in water, yielding a sweet and almost colorless solution which is not changed by acids, but is deeply reddened by alkalis. In alcohol and ether it is somewhat more soluble than in water, giving a light yellow solution. *Brasilin* and *hematoxylin* (from logwood) are both now recognized as related, and as derived from the pyrone nucleus $C_6H_4O_2$, from which the two groups, the xanthone group and the flavone group, are also taken. The coloring principles of most dye-woods are now referred to this source. (Kupe, *Die Chemie der natürlichen Farbstoffe*, Braunschweig, 1900.)

Brea Gum.—This substance, which has been proposed as a substitute for gum arabic, is believed to be derived from *Casalpinia præcox*, a Brazilian tree. It occurs in stalactitic pieces or oval reddish-yellow tears, isolated or agglomerated. It forms with water a viscous pale reddish-yellow mucilage, of acid reaction, which may be partially decolorized by heating with a few drops of hydrochloric acid. It is said to contain 77 per cent. of arabin.

Bremen Blue or Bremen Green.—This substance, chemically, is *cupric hydrosulphide*, although sometimes *cupric carbonate* is sold under the same name. It is made by precipitating a copper salt with an alkali, and drying the precipitate below 40° C. (104° F.). When used as a water-color, it is blue, but when mixed with oil, a soap is formed which is of a green color.

Bromal. C_2HBr_3O .—This substance resembles chloral in its chemical properties, like it existing as an oily colorless liquid, or, when united with water or alcohol, as a crystalline hydrate or alcoholate. It boils at about 172° C. (341.6° F.), and distils without decomposition. It is prepared by adding, little by little, from 3 to 4 parts of bromine to refrigerated alcohol. After fifteen hours of contact the mixture is distilled. The excess of bromine and the other volatile products come over first, and afterwards, at a temperature of from 160° C. (320° F.) to 180° C. (356° F.), the bromal, with an oily substance insoluble in water. Water being added, *bromal hydrate*, $C_2HBr_3O \cdot H_2O$, is formed in rhombic scales fusing at 53.6° C. (128° F.). By the action of an alkali, bromoform is produced from the bromal hydrate. According to S. Steinauer (*V. A. P. A.*, May 19, 1870), in frogs and mammals bromal produces at first great restlessness, followed by sleep of moderate intensity, accompanied by an almost complete analgesia. Dyspnoea was usually very marked, and death sometimes occurred in convulsions. The cardiac ventricles after death were relaxed or tetanized, according as the dose had been large or small. Steinauer believes that the succession of symptoms is due to the first action being that of the bromal, and the subsequent, that of bromoform and nascent bromides generated in the blood from the bromal hydrate. Steinauer administered the drug to several patients, in

doses of three grains (0.2 Gm.) at bedtime, with the effect of relieving pain or producing sleep. In *epilepsy* it seemed to avert the paroxysms.

Bromalin. *Bromethylformin.*—*Hexamethylene-tetramine-bromethylate*, $(\text{CH}_2)_6\text{N}_4\cdot\text{C}_2\text{H}_5\text{Br}$, is formed by the action of ethyl bromide upon hexamethylenetetramine. It occurs in colorless scales or white powder, melting at 200°C . (392°F .) with decomposition; nearly tasteless, readily soluble in water. It has been used, especially by Bardet, as a sedative and substitute for the bromides. The dose is from thirty to sixty grains (2.0–3.9 Gm.).

Bromamide. *Tribromaniline Hydrobromide*. $\text{C}_6\text{H}_2\text{Br}_3\text{NH}_2\text{HBr}$.—This substance, which is said to contain 75 per cent. of bromine, and to be very stable, occurs in odorless, tasteless, colorless, needle-shaped crystals, insoluble in water, but soluble in sixteen parts of boiling alcohol, in chloroform, ether, and the fixed oils. It melts at 117.2°C . (243°F .), and volatilizes at 154.4°C . (310°F .) without change. It has been proposed by A. Caille (*N. Y. M. J.*, 1892) as an antipyretic, antirheumatic, and analgesic. Dose, from ten to fifteen grains (0.65–1.0 Gm.).

Bromine Chloride. *Bromi Chloridum*. BrCl . This chloride is prepared by passing chlorine gas through bromine, and condensing the vapors which form, by a freezing mixture. It is a reddish-yellow, very mobile and volatile liquid, emitting dark yellow fumes, which have a very powerful odor and cause a flow of tears. Its taste is hot and unpleasant. Bromine chloride is used by Landolfi of Naples, internally, in the treatment of cancer and as an ingredient in his caustic.

Bromipin.—*Brominized Sesame Oil* is probably a simple addition compound of bromine with the unsaturated oleins of sesame oil. The exact composition of this substance is not known, but it is asserted to be a stable combination of bromine and sesame oil. It is claimed for it that it has the sedative powers of potassium bromide and other alkaline bromides, but does not produce disturbances of the intestinal tract, skin, and general system which occur in bromism. It has been highly recommended by a number of clinicians for the relief of *epilepsy*, *insomnia*, *cardiac symptoms*, and other disturbances occurring in *neurasthenia*. It may be given hypodermically or dissolved in oil and rubbed into the skin; after either method of administration bromine soon appears in the urine. Bromipin is a clear, oily liquid, which was supplied by the manufacturer in two strengths,—one containing 10 per cent. and the other 33½ per cent. of bromine. It must be given in capsules or dissolved in cod liver oil. According to *Merck's Report*, 30 grains of the stronger bromipin are equivalent to 15 grains of potassium bromide. The 10 per cent. solution is now (1905) the only one quoted in *Merck's Manual*; the adult dose of this is one fluidrachm (3.75 Cc.); in *epilepsy* two fluidrachms to one fluidounce (7.5 to 30 Cc.) have been given. Dose, for children, about one-half the adult dose.

Bromochinal. *Quinine Bromsalicylate*.—Bromochinal occurs in yellow crystals, sparingly soluble in water, alcohol, or ether. According to von Noorden, in doses of nine to twelve grains (0.6–0.78 Gm.) given twice a day, it acts as a feeble antipyretic and is also soporific. (*Ther. Geg.*, v.)

Bromocoll. *Dibromtannin-gelatin*.—This is a yellow, tasteless, odorless powder, composed of 20 per cent. of bromine, 10 per cent. of water, 30 per cent. of gelatin, and 40 per cent. of tannic acid. According to the experiments of Brat (*Th. M.*,

xv. 4, 1901), bromocoll is very resistant to gastric juice, but is readily dissolved with decomposition in the intestinal juices. It is claimed that it acts precisely like the older bromides, and produces the disagreeable symptoms of bromism, only in a very mild degree. Friedländer (*Th. M.*, 1901) determined by experiments that it depresses the irritability of the psychomotor centres. The dose is thirty to seventy-five grains (2–5 Gm.) a day.

Bromol. *Tribromophenol.* *Tribromphenol*. $\text{C}_6\text{H}_2\text{Br}_3\text{OH}$.—Bromol is obtained as a white flocculent and gradually crystallizing sediment when bromine water is added to an aqueous solution of phenol. Pure tribromophenol occurs as a white crystalline substance which melts at a temperature of 92°C . (197.6°F .), and is nearly insoluble in water, but readily so in alcohol, ether, chloroform, glycerin, and in fatty and ethereal oils; the odor is disagreeable, like that of bromine, but more penetrating; the taste is sweet and astringent. According to Grimm and Rademacher, tribromophenol is a powerful antiseptic and disinfectant, which, when in concentrated form, acts as a caustic, and is especially valuable in the treatment of tuberculous ulcers and gangrene. Grimm considered the remedy too caustic to be used upon the mucous membrane of the upper air-passages, but Rademacher has used it in the solution of olive oil (one to thirty) with asserted excellent results in *diphtheria*. It is said to be very slowly acted upon by the intestinal juices, and has been used as an intestinal disinfectant in doses of from three to eight grains (0.2–0.5 Gm.) a day. That it is absorbed in some form is shown by the fact of its excretion in the urine in the form of *tribromophenol-sulphonic acid*.

Bromolein is an addition product of bromine in which the unsaturated fatty oleins of the almond oil have taken up the bromine necessary for their saturation. This substance, introduced by Coronedi and Marchetti (*Settimana med.*, liii. 1899) is a yellow, clear, oily liquid, containing 20 per cent. of bromine combined with olein of the oil of sweet almonds. It is asserted that it may be used hypodermically or upon the skin, and affords an excellent means of using the bromides in nervous diseases, acting like the older bromides without causing bromism. It is said also not to be decomposed by the enzyme of the pancreas. Theoretically the dose of bromolein is about three times that of potassium bromide.

Bromopyrin. *Monobromantipyrin*. $\text{C}_{11}\text{H}_{11}\text{BrN}_3\text{O}$.—This occurs in white crystalline needles, almost insoluble in cold water, scarcely soluble in hot water, easily soluble in alcohol and chloroform. Its melting point is 114°C . (237.2°F .). Its influence upon the system seems not to have been investigated. A mixture of antipyrine, caffeine, and sodium bromide has been sold as bromopyrin.

Brunswick Green.—A color pigment, chemically either copper oxycarbonate or oxychloride.

Bryonia. *U. S.* 1890. *Bryonia*.—"The root of *Bryonia alba*, and of *Bryonia dioica* Linné (nat. ord. *Cucurbitaceæ*)." *U. S.* 1890.

Bryonia alba, or *white bryony*, is a perennial, climbing, herbaceous plant with monococious flowers, growing in thickets and hedges in different parts of Europe. Another species, *B. dioica*, with dioecious flowers and red berries, bears so close a resemblance in character and properties to the preceding that it is considered by some botanists merely a variety. The roots of both plants are gathered for use. When fresh they are spindle-

shaped, sometimes branched, a foot or two in length, as thick as the arm, or even thicker, externally yellowish gray and circularly wrinkled, within white, succulent, and fleshy, of a nauseous odor, which is lost in great measure by drying, and of a bitter, acrid, very disagreeable taste. The peasants are said sometimes to hollow out the top of the root, and to employ the juice which collects in the cavity, as a drastic purge. (Mérat and De Lens.) The berries are also purgative, and are used in dyeing. *B. americana*, Lam., and *B. africana*, Thunb., are respectively used in the West Indies and Africa as hydragogue cathartics in dropsy. The berries of the European *black bryony* (*Tamus communis*, L.), are said to be an irritant poison, and Coutagne has found that their tincture causes in animals paralysis and convulsions. (See *Rép. de Pharm.*, Nov. 1884; also *P. J.*, Jan. 1903.)

As kept in the shops bryonia occurs in transverse sections "about 5 Cm. in diameter, the bark gray-brown, rough, thin, the central portion whitish or grayish, with numerous small, projecting wood-bundles arranged in circles and radiating lines; fracture short; inodorous; taste disagreeably bitter." *U. S.* 1890. Besides a peculiar glucoside called *bryonin*, the root contains a resin, to which the name of *bryoresin* has been given. It yields its active properties to water. Bryonin, $C_{24}H_{50}O_8$, may be obtained by exhausting the coarsely pulverized root in the cold with water containing 3 per cent. of hydrochloric acid. This acid aqueous liquid is then treated with tannin until no further precipitate occurs, the precipitate treated first with water containing HCl and then with distilled water, dried, pulverized, and dissolved in 90 per cent. alcohol; the solution is filtered, decomposed with zinc oxide, and the resulting mass exhausted with cold distilled water. This on evaporation yields impure bryonin, which is purified by dissolving it in water containing hydrochloric acid and dialyzing it. It is white, amorphous, very bitter, soluble in water and alcohol, insoluble in ether and chloroform. It is dextrogyrate and precipitates tannin and ammoniacal lead acetate. The root thus exhausted with water and dried, when treated with 90 per cent. alcohol, yields the bryoresin. This is soft at 15° C. (59° F.), red, amorphous, soluble in alcohol, ether, chloroform, glacial acetic acid, and alkalis. Bryonin, boiled with dilute sulphuric acid, yields a glucose and a yellowish, amorphous resin, *bryogenin*. This latter is soluble in alcohol, insoluble in ether. (Masson, *J. P. C.*, 1893, 300; see also C. F. Heller, *A. J. P.*, 1887, 68.)

Bryonia is an active irritant hydragogue cathartic. In a number of cases it has produced serious or even fatal poisoning. Vomiting and purging have been commonly present, but in some cases there has been no diarrhoea. Giddiness, delirium, and dilated pupils, coupled with fall of the bodily temperature, imperceptible pulse, cold perspiration, and other manifestations of collapse, are the usual symptoms. Eighty minims (5 Cc.) of the homœopathic tincture caused very serious but not fatal poisoning. (For cases see *P. J.*, 1858, p. 542; *L. L.*, May 9, 1868; *B. M. J.*, 1883, ii. 1067; *T. G.*, ii. 35; also Woodman and Tidy.) The recent root is highly irritant, and is said, when bruised and applied to the skin, to be capable of producing vesication. The medicine was well known to the ancients, and has been employed as a hydragogue cathartic in dropsy. Dose, twenty grains to a drachm (1.3-3.9 Gm.).

Tinctura Bryoniæ. U. S. 1890. *Tincture of Bryonia*.—"Bryonia, recently dried, and in No. 40 powder, one hundred grammes [or 3 ounces av., 231 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with one hundred cubic centimeters [or 3 fluidounces, 183 minims] of Alcohol, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour Alcohol upon it, until one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Tincture are obtained." *U. S.* 1890. Dose, from one to two fluidrachms (3.75-7.5 Cc.).

Burra Gookeroo.—Under this name, in India, the fruit and sometimes the whole plant of the *Tribulus lanuginosus* (Fam. Zygophyllaceæ) is used as a diuretic and aphrodisiac. The carpels have been commended in London as a remedy in nocturnal emissions; dose of fluidextract, from twenty minims to one fluidrachm (1.3-3.75 Cc.).

Butea Gum. *Butea Gummi. Br. Add. Bengal Kino.*—The inspissated juice obtained from incisions in the stem of *Butea frondosa*, Roxb. The Sacred Tree (*Butea frondosa*) enters largely into the religious rites of the Hindoos. Its red flowers are offered at the bloody sacrifice of the goddess Kali. Its leaf with three spreading leaflets is supposed to represent the Hindoo deity, and furnishes platters used when the Hindoo boy becomes of age. Butea gum occurs in small, irregular, shining, odorless fragments, which by exposure become dull and blackish. It is partially soluble in water and yields to hot 90 per cent. alcohol about 40 per cent., the solution being scarcely colored. It is said (Hanbury) to yield 1.8 per cent. of ash and 13.5 per cent. of water, and to be composed of about equal parts of a kinotannic acid and a soluble mucilaginous substance. On dry distillation it yields pyrocatechin, which, according to Eissel, does not preëxist in it. The Br. Add. permits of its substitution for true kino in India and the eastern colonies, and its therapeutic properties are undoubtedly those of kino.

The Br. Add. recognizes under the name of BUTEÆ SEMINA the seeds of *Butea frondosa* and describes them as "flat and reniform, from one to one and one-half inches (25 to 38 Mm.) long, from three-quarters of an inch to one inch (16 to 25 Mm.) wide, and from one-sixteenth to one-twelfth of an inch (1½ to 2 Mm.) thick. The testa is thin, glossy, veined, wrinkled, and of a dark reddish-brown color. There is a large prominent hilum situated in the middle of the concave edge. The cotyledons are large, leafy, and of a yellow color." The butea seeds have been specially used by Tamil practitioners against the tape worm and ascarides and in dose of six fluidrachms twice daily (22.5 Cc.). (Ainslie.) According, however, to the authors of the *Pharmacographia India* the infusion of three seeds is distinctly aperient.

The Br. Add. directs that butea seeds shall be soaked in water, the integument carefully removed, and the dried kernels ground to powder (*Pulvis Buteæ Seminum*, Br. Add.); dose, ten to twenty grains (0.65-1.3 Gm.).

Butylchloral-Antipyrine. $C_{11}H_{12}N_2O.C_4H_5Cl_3$ O + H₂O.—This compound results when antipyrine and butylchloral hydrate, in the proportion of 188 parts of the former to 193.5 parts of the latter, are triturated together; the resulting oily liquid dissolved in hot water, and the solution set aside to crystallize. It is in the form of colorless, needle-like crystals, melting at 70° C. (158° F.),

and soluble in about 30 parts of water. *Dose*, of butylchloral-antipyrine, from five to twenty grains (0.32 to 1.3 Gm.) as an analgesic and hypnotic.

Butyric Acid. *Acidum Butyricum*.—(See *Fruit Essences*.)

Buxus. *Buxus sempervirens*, L. Boz. (Fam. Buxaceae).—This evergreen shrub is too well known to require description. Though much cultivated in this country as an ornamental plant, it is a native of Europe and Western Asia. The wood is considered diaphoretic in its native countries, and is used in decoction in *rheumatism*, *secondary syphilis*, etc. The leaves, which have a peculiar odor and a bitter and disagreeable taste, are said to be purgative in the *dose* of a drachm. A volatile oil distilled from the wood has been given in *epilepsy*. A tincture formerly enjoyed some reputation as an antiperiodic. (Mérat and De Lens.) In 1860 it was determined by Walz that *buxine*, an alkaloid which had been discovered in the leaves of this tree, is identical with the bebeerine of the bebeeru or nectandra bark. (See *Nectandra*; also *P. J.*, Oct. 1869, 194.) Pavia obtained a second alkaloid from *Buxus sempervirens*, which was investigated by Pavesi and Rotondi. (*Jahresberichte*, 1874, 903.) They named it *parabuxine*, and ascribed to it the formula $C_{24}H_{48}N_2O$. Barbaglia (*A. J. P.*, 1885, 145) described still another alkaloid, *parabuxinidine*. It crystallizes in thin, colorless prisms, is insoluble in water, soluble in ether, freely soluble in alcohol, and colors turmeric paper deep red.

Cabbage-Tree Bark. *Ecoore* de Geoffree, Fr. *Kohlbaumrinde*, Wurmrinde, G.—The bark of *Vouacapoua inermis* (Swz.), Lyons. (*Andira inermis*, H. B. K. *Geoffræa inermis*, Sw.) This is a leguminous tree, with a stem rising to a considerable height, branched towards the top, and covered with a smooth gray bark. The tree is a native of Jamaica, and other West India islands. The bark, which is the part used, is in long pieces, thick, fibrous, externally of a brownish-ash color, scaly, and covered with lichens, internally yellowish, of a resinous fracture, a disagreeable odor, and a sweetish, mucilaginous bitterish taste. Its power resembles that of jalap. Huttenschmidt obtained from it a crystallizable, very bitter substance, having the composition and neutralizing properties of the vegetable alkaloids, and named it *jamaicine*. Two grains (0.13 Gm.) of it produced violent purging in pigeons.

Theodore Peckoldt says of the wood of an allied species, *Andira anthelmintica*, Benth., that the workmen engaged in sawing it are prone to be affected with inflammation of the eyes, constriction of the throat, excessive thirst, a bitter, burning taste, a troublesome itching over the body, and sometimes eruptions on the skin. By treating a concentrated decoction of the wood with calcium hydroxide, then filtering after forty-eight hours, evaporating to the consistence of syrup, and exhausting the residue with alcohol, Peckoldt obtained a yellowish-brown coloring matter which he called *andirin*. (This name has also been given to a glucoside said to have been found in *Vouacapoua inermis*. See *A. J. P.*, 1885, 558.) Peckoldt also obtained a peculiar resin by treating the wood with alcohol, filtering, distilling off most of the alcohol, and then precipitating by water. The resin is inodorous, of a bitter, acid taste, soluble in alcohol, and but partially soluble in ether. This resin, and especially the portion soluble in ether, gives its irritating properties to the sawdust. (*Chem. Ob.*, Nov. 17, 1858.)

Cabbage-tree bark is cathartic, and, in large doses, prone to occasion vomiting, fever, and delirium. It is said that these effects are more liable to result if cold water be drunk during its operation, and may be relieved by the use of warm water, castor oil, or a vegetable acid. In the West Indies it is esteemed a powerful vermifuge, and is much employed for expelling *lumbri*; but it is dangerous if incautiously administered, and instances of death from its use have occurred. It is almost unknown in this country. The usual form of administration is that of decoction, though the medicine is also given in powder, syrup, and extract. The *dose* of the powder is from twenty to thirty grains (1.3–2.0 Gm.); of the extract three grains (0.2 Gm.).

On the continent of Europe the bark of *Vouacapoua retusa* (Poir), Lyons (*Andira retusa*, H. B. K., *Geoffræa surinamensis*, Bondt.), which grows in Surinam, has also been used. It is considered more powerfully vermifuge and less liable to produce injurious effects. It has a grayish epidermis, beneath which it is reddish brown, laminated, compact, and very tenacious, and when cut transversely, exhibits a shining and variegated surface. In the dried state it is inodorous, but has an austere bitter taste. The powder is of a pale cinnamon color.

Cacodylic Acid. *Acidum Cacodylicum*. As $(CH_3)_2OOH$.—Cacodylic acid is a deliquescent, crystalline, and odorless solid, which is, however, chemically quite stable. It is very soluble in water with an acid reaction. Cacodylic acid is *dimethyl-arsenic acid*; that is, arsenic acid in which two hydroxyl radicles have been replaced by two methyl radicles. In the metallic cacodylates the hydrogen in the remaining hydroxyl is replaced by the base; sodium cacodylate is, therefore, As $(CH_3)_2OONa$; potassium cacodylate, As $(CH_3)_2OOK$, etc. In recent times cacodylic acid has been very largely used as a substitute for the older preparations of arsenic in the treatment of *psoriasis*, *neurasthenia*, and other diseases of the skin or the nervous system, being employed in those cases in which Fowler's solution has been commonly used. It has been variously alleged that it is very active and that it is almost free from toxic properties, a divergence of statement which seems to be reconciled by the researches of John Marshall and Howard Green (*Am. Chem. J.*, May, 1886), who found that commercial cacodylic acid was quite active in rabbits, and then determined that this activity was due to the presence of free arsenic trioxide.

Chemically pure cacodylic acid had to be given in enormous doses to have any effect, but when administered to the rabbit in repeated doses of seven grains (0.45 Gm.) it produced vomiting, diarrhœa, profuse salivation, staggering gait, followed in one case by death. It would seem, therefore, to be a very feeble arsenical preparation. There is little reason for supposing that it is essentially different in its therapeutic action from the more ordinary preparations of arsenic, its remedial properties being in all probability directly proportionate to its toxic—that is, its physiological activity. This conclusion is sustained by two facts which the published clinical records make very clear,—namely, that in order to be at all effective in disease cacodylates must be given in extraordinary doses, and that occasionally the exhibition of comparatively small doses is followed by very violent symptoms of arsenical

poisoning. (See Murrell, *B. M. J.*, No. 2086.) It is most probable that in the latter cases the cacodylate has contained free arsenous acid. Pure cacodylic acid may be used itself internally in doses of one-half to two grains (0.032–0.13 Gm.), but is commonly administered in the form of a salt. The following preparations have been suggested:

Calcium Cacodylate. Calcii Cacodylas.

A white powder, soluble in water.

Iron Cacodylate. Ferri Cacodylas.—A grayish-yellow amorphous powder freely soluble in water, especially when heated, less soluble in alcohol. This salt has been specially recommended by Gilbert and Lereboullet (*R. T.*, 1900, No. 16) for hypodermic use in the treatment of *leucocythæmia*, *lymphadenoma*, and other serious anæmias. It is too irritant to be used in concentrated solution, but as much as one grain (0.065 Gm.) dissolved in half a fluidrachm (1.8 Cc.) of water may be injected daily.

Guaiacol Cacodylate.—A reddish-white crystalline mass, which dissolves in alcohol and parts with cacodylic acid in the presence of water. Dissolved in oil it has been employed hypodermically in *tuberculosis*.

Mercury Cacodylate. Hydrargyri Cacodylas. White crystals freely dissolving in water, but sparingly soluble in alcohol. We have no definite knowledge of the physiological action of this salt, but it is said to have been used by Dayas hypodermically in doses of half a grain (0.032 Gm.). One and a half grains (0.096 Gm.) is affirmed to be the fatal dose for the rabbit.

Lithium Cacodylate. Lithii Cacodylas.

A light white powder, soluble in water. Dose, one-half to two grains (0.32–0.13 Gm.).

Magnesium Cacodylate. Magnesii Cacodylas.

A white powder, soluble in water. Dose, one-half to two grains (0.032–0.13 Gm.).

Potassium Cacodylate. Potassii Cacodylas.

Small white crystals, soluble in water, but sparingly soluble in alcohol and insoluble in ether.

Quinine Cacodylate. Quininae Cacodylas. $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2(\text{CH}_3)_2\text{AsOOH}$.—A white powder, more freely soluble in cold than in hot water, but freely soluble in alcohol. Dose, one-half to two grains (0.032–0.13 Gm.).

Sodium Cacodylate. Sodii Cacodylas.

Of all the preparations of cacodylic acid the sodium cacodylate is usually preferred. It especially lends itself to hypodermic use, and may be given in ten per cent. solution. One-fourth of a grain (0.016 Gm.) may be administered at first, and the dose rapidly increased until some evidences of physiological action are produced; or as much as two (0.13 Gm.) or even three grains (0.2 Gm.) of the salt are given in the day. Sodium cacodylate has also been administered to a considerable extent by the rectum. Various clinicians report daily doses of four grains (0.26 Gm.) without injury.

Cactus.—Cardiac stimulant properties have been attributed to two Cacti,—namely, *Cereus*

Bonplandii, H. B. K., *Cereus grandiflorus* (L.), Miller (*Cactus grandiflorus*, L. *Night-blooming Cereus*, *Cierge à grandes fleurs*, Fr. *Königin der Nacht*, G.) Of these the latter only is now used in practical medicine. It is a native of tropical America, often cultivated in hot houses for the sake of its very fragrant night-opening white flowers. F. W. Sultan (*A. J. P.*, 1891, 424) believed that he had found in it an alkaloid, *cactine*, but the existence of this alkaloid is extremely doubtful.

Cereus grandiflorus has long been used in tropical America in the treatment of *dropsy*. It was first brought into notice as a cardiac remedy by Rubini of Naples. According to O. M. Myers (*N. Y. M. J.*, June, 1891) it elevates the arterial tension by increasing the muscular energy of the heart, and by contracting the arterioles through the vasomotor centres. These conclusions have been partially confirmed by Boy-Teissier and Boinet (*Marseilles Méd.*, 1891). Considerable clinical testimony has been given to the value of cactus as a cardiac stimulant and as a partial substitute for digitalis in the functional disorders of the heart connected with *dyspepsia*, *neurasthenia*, *anæmia*, *Graves's disease*, *tobacco toxicæmia*, *sexual exhaustion*, and allied affections. It is alleged that cactus does not prolong the diastolic pause, and is valuable in *aortic regurgitation*.

Notwithstanding the scientific and clinical evidence already spoken of, cactus is probably of little or no value in practical medicine. In careful therapeutic trials with it we have failed to get any results whatsoever. Sharp could only obtain from the drug resins which were inactive and concludes that it is inert. (*Pract.*, Sept. 1894.) Moreover, cactus, except in the fresh state as it is ordered by manufacturers from tropical countries, has disappeared entirely from the American drug market,—a sub-committee of the U. S. Pharmacopœial Committee of Revision, after a year's search, was not able to get a single specimen of it. According to P. W. Williams, the maximum dose of the tincture (four ounces of the fresh stems to a pint of strong alcohol) is thirty minims (1.8 Cc.) every four hours, and of the fluidextract twelve minims (0.7 Cc.).

From *Cereus pectene*, Heyl separated an alkaloid, *pectenine*, which, according to Heffter (*A. Pharm.*, cexxxix. S. 462, 1901), produced both in cold and warm blooded animals tetanic convulsions with heightened reflexes. According to the experiments of Mogilewa, the alkaloid acts upon the isolated frog's heart as a depressant.

From *Cereus pilocereus*, Heyl separated the alkaloid *pilocerine*, which Heffter found to produce in frogs central paralysis with great cardiac depression, and in warm blooded animals to kill by cardiac arrest. Mogilewa found this alkaloid to act upon the frog's heart as a direct depressant to the muscle structure.

Anthelmintic properties have been ascribed to *Cereus flagelliformis*, Miller, and to *C. divaricatus*, Lam., DC.

Cacur.—This is a small gourd which while still unripe is used by the Caffirs as an emetic, and which, according to Oliver, is yielded by the *Cucumis myriocarpus*, Nand. (Fam. Cucurbitaceæ.) G. A. Atkinson (*A. J. P.*, 1887) obtained from it a neutral resinous body, *myriocarpin*, and found that twenty grains (1.3 Gm.) of the fresh pulp produced in man nausea and slight purgation. (*Ed. M. J.*, July, 1886.)

Cadmium. *Kadmium*, G.—This metal is associated with zinc in its ores, occurring principally as *greenockite* (CdS), a yellowish incrustation upon *zinc blende* (ZnS), and, being more volatile than that metal, comes over with the first portions of the zinc in the process for obtaining it. (See *Zincum*.) The cadmium is separated by dissolving the alloy metals in diluted sulphuric acid, precipitating the sulphate by hydrogen sulphide, treating the precipitate with hydrochloric acid, and again precipitating with ammonium carbonate. The cadmium carbonate thus obtained, after being washed and dried, is mixed with charcoal, and exposed to a dull red heat in an earthen retort, when the reduced metal distills over.

Properties.—Cadmium is a white metal, resembling tin, but somewhat heavier and more tenacious. Like that metal, it crackles when bent. Its sp. gr. is 8.7, melting point from 316° to 320° C. (600.8° – 608° F.). It begins to volatilize at a temperature slightly above this, but under the boiling point of mercury, while it boils only at 770° C. (1418° F.). It is little affected by the air, but, when heated, combines with an atom of oxygen, forming a reddish-brown or orange-colored oxide, CdO , which combines with the acids to form salts. From its saline solutions the oxide is precipitated by the alkalis in the form of a white hydroxide. Cadmium also combines with chlorine, iodine, bromine, and sulphur. It is distinguished by forming a colorless solution with nitric acid, from which hydrogen sulphide or ammonium sulphide precipitates a lemon-yellow sulphide insoluble in an excess of the reagent or in solution of potassium hydroxide or ammonia water, and not volatilized at a red heat. Potassium hydroxide produces a white precipitate insoluble in an excess, and ammonia a similar precipitate soluble in an excess of the precipitant. Zinc precipitates cadmium in the metallic state. "A neutral solution of the metal in nitric acid, after having been fully precipitated by carbonate of sodium in slight excess, yields a filtrate which is not affected by ammonium sulphide." *U. S.* 1870. This test was intended to prove the absence of arsenic.

Cadmium Iodide. *Cadmii Iodidum*. (CdI_2 . Mol. wt. 363.4.) *Cadmium Iodatum*, *Iodidum Cadmicum*. *Iodure de Cadmium*, Fr. *Jodcadmium*, *Kadmiumjodür*, G.—Cadmium iodide may be prepared by mixing iodine and filings of cadmium in a moist state, or by dissolving the metal in hydriodic acid, or by double decomposition between potassium iodide and cadmium sulphate. It is soluble in water and alcohol, and may be crystallized from either solution, in large, white, transparent crystals, in the form of six-sided tables, of a pearly lustre. These are permanent in the air, melt at 404° C. (759.2° F.), forming an amber-colored liquid, and give off violet vapors at a dull red heat. The salt is freely soluble in water and in alcohol, and the solution has an acid reaction. The Br. Pharmacopœia of 1867 gives the following tests. The aqueous solution gives a yellow precipitate with hydrogen sulphide or ammonium sulphide, insoluble in excess of the sulphide, and a white gelatinous precipitate with excess of solution of potassium hydroxide, the filtrate from which is unaffected by ammonium sulphide. Ten grains dissolved in water give with an excess of silver nitrate a precipitate which, washed with water and afterwards with half an ounce of water of ammonia and dried, weighs 12.5 grains.

Cadmium Salicylate. *Cadmii Salicylas*. $\text{Cd}(\text{C}_5\text{H}_4\text{OHCOCOO})_2$, is prepared by acting on cadmium oxide with salicylic acid. It is colorless and crystalline, soluble in 24 parts of boiling water, and in alcohol, ether, and glycerin. It is used as an antiseptic.

Cadmium Sulphate. *Cadmii Sulphas*. *Cadmium Sulfuricum*. *Sulfas Cadmicus*. *Sulfate de Cadmium*, Fr. *Schweifelsaures Cadmiumoxyd*, *Kadmiumsulfat*, G. $\text{CdSO}_4 \cdot 4\text{H}_2\text{O}$.—"Take of Cadmium, in small pieces, a troyounce; Nitric Acid two troyounces; Carbonate of Sodium three troyounces; Sulphuric Acid four hundred and twenty grains; Distilled Water a sufficient quantity. To the Cadmium and two fluidounces of Distilled Water, contained in a glass vessel, add by degrees the Nitric Acid, and, when the action slackens, apply a gentle heat until the metal is dissolved. Filter the solution, and, having dissolved the Carbonate of Sodium in six fluidounces of Distilled Water, mix the solutions thoroughly. Wash the precipitate obtained until the water passes tasteless, and dissolve it in the Sulphuric Acid, diluted with four fluidounces of Distilled Water. Then evaporate the solution to one-third, and set it aside to crystallize. Lastly, dry the crystals on bibulous paper." *U. S.* 1870.

Cadmium sulphate crystallizes in oblique prisms with rhomboidal bases, which are transparent and colorless, and resemble those of zinc sulphate. They have an astringent, slightly acidulous, and austere taste, effloresce on exposure to the air, and are very soluble in water. The solution, even though acidulated, gives with hydrogen sulphide a yellow precipitate, becoming orange-yellow, of cadmium sulphide, which is dissolved by strong hydrochloric acid, but is insoluble in solutions of potassium hydroxide or ammonia, and is thus readily distinguished from arsenic sulphide. With ammonium sulphide it gives a yellow precipitate insoluble in an excess of the sulphide. Ammonia produces a white precipitate, soluble in an excess of the precipitant; ammonium carbonate a white one insoluble in an excess; potassium ferrocyanide a white precipitate not dissolved by hydrochloric acid; and the ferricyanide a brownish-yellow one soluble in a large excess of that acid. (Brande and Taylor.) By these tests cadmium sulphate is distinguished as a salt of that metal. As a sulphate it is known by yielding a precipitate with barium chloride not soluble in nitric acid. Zinc precipitates cadmium in the metallic state from the solution. Cadmium suspended in a solution of copper sulphate precipitates that metal, leaving cadmium sulphate in solution, and this has been proposed as a method of obtaining the salt.

Medicinal Uses of Cadmium.—It is probable that the insoluble preparations of cadmium are not actively poisonous, but it is certain that the soluble preparations are corrosive poisons, causing in overdoses giddiness, vomiting, purging, slowing of the pulse and respiration, loss of consciousness, and spasm. In three cases in which the carbonate is said to have been inhaled, the chief symptoms were constriction of the throat, embarrassed respiration, vomiting and purging, giddiness, and painful spasms. (*Ann. Thér.*, 1859.) For a case of poisoning by the bromide, see *B. M. S. J.*, 1876.

¹ The ordinary crystals of cadmium sulphate have the formula $\text{CdSO}_4 \cdot 8\text{H}_2\text{O}$, and, at very low temperature, $\text{CdSO}_4 \cdot 7\text{H}_2\text{O}$.

It has been shown by Athanasius and Langlois (*C. R. S. B.*, ii. 1895) that the soluble salts of cadmium act very powerfully in arresting the lactic fermentation. When given hypodermically to the frog they produce symptoms similar to those caused by zinc salts, than which, however, they are less powerful; the symptoms are rapid loss of voluntary motion with persistence of the reflexes and pronounced cardiac depression. In the higher animals there is destruction of the red blood corpuscles.

Cadmium sulphate has been used to a considerable extent as a local astringent and stimulant in diseases of the eye and in gonorrhœa, and is believed by many oculists to have special power in relieving specks and opacities of the cornea. It is employed either in solution, from half a grain to four grains to the fluidounce of distilled water, or in ointment, twelve grains to the ounce of simple ointment.

Cadmium iodide was introduced by A. B. Garrod as an external remedy in the treatment of scrofulous glands, nodes, chronic inflammation of joints, and various cutaneous diseases. The ointment, which was formerly official in the British Pharmacopœia under the name of *Unguentum Cadmii Iodidi* (sixty-two grains to one ounce of simple ointment), is soft, white, and said to readily yield its iodine to absorption when applied by persistent gentle friction.

Cæsium.—The physiological effect of cæsium chloride has been investigated by S. Botkin (*In. Dis.*, St. Petersburg, 1888.) He finds that it increases the blood pressure and retards the heart movement to a slight extent. Laufenauer (*Th. M.*, 1889, and *Pester Med. Chirurg. Presse*, 1889) asserts that cæsium bromide theoretically ought to, and practically does, control epilepsy better than do the ordinary bromides. The physiological and medicinal properties of rubidium have also been studied by these investigators and found to resemble those of cæsium. This investigation has led to the putting upon the market, by Merck, of the following preparations:

Rubidium and Ammonium Bromide ($\text{RbBr} + 3\text{NH}_4\text{Br}$).—A white or slightly yellowish, crystalline powder, readily soluble in water. Its taste is somewhat cooling at first, and pungently saline afterwards. This salt, one hundred parts of which contain thirty-six parts of rubidium bromide and sixty-four of ammonium bromide (NH_4Br), was especially used by Laufenauer in doses of from one to two drachms (3.9–7.7 Gm.).

Cæsium and Ammonium Bromide ($\text{CsBr} + 3\text{NH}_4\text{Br}$).—A white, crystalline powder, readily soluble in water.

Cæsium Carbonate (Cs_2CO_3).—Sand-like, white; melting at red heat; very hygroscopic; very soluble in water; soluble also in alcohol.

Cæsium Hydroxide (CsOH).—A grayish-white mass melting below red heat; rather deliquescent, behaving towards water or alcohol as potassium hydroxide does.

Cæsium Sulphate (Cs_2SO_4).—Anhydrous, colorless prisms, permanent in the atmosphere; extremely soluble in water; insoluble in alcohol.

The triple salt **Cæsium, Rubidium, and Ammonium Bromide** is also used.

Caffeine Hydrobromide. *Caffeinæ Hydrobromidum*, *Caffeinum hydrobromicum*, *Koffeinhydrobromat*, *Bromwasserstoffsaures Koffein*, *G.* $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot \text{HBr} + 2\text{H}_2\text{O}$.—In the form of transparent crystals, readily decomposed but more stable than the hydrochloride. When heated to

110° C. (230° F.) the hydrobromic acid is driven off. Used for nervous headaches and as a diuretic, injected subcutaneously.

Caffeine Hydrochloride. *Caffeinæ Hydrochloridum*, *Caffeinum Hydrochloricum*, *Koffeinhydrochlorat*, *Salzsaures Koffein*, *G.* $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot \text{HCl} + 2\text{H}_2\text{O}$. Large, colorless, prismatic crystals, readily decomposed by washing with alcohol or water or by long exposure to the air, when water and chlorine are lost. If heated to 110° C. (230° F.) the chlorine is driven off. The normal salt contains about 73 per cent. of caffeine.

Caffeine Nitrate. *Caffeinæ Nitras*, *Caffeinum Nitricum*, *Koffeinnitrat*, *Salpetersaures Koffein*, *G.* $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot \text{HNO}_3 + \text{H}_2\text{O}$.—In the form of yellowish crystals, quickly decomposed by water and alcohol. The salt contains about 70 per cent. of caffeine and all the nitric acid is driven off at a temperature of 100° C. (212° F.).

Caffeine Phenylate. *Caffeinæ Phenylas*, *Caffeinum Phenylicum*, *Caffeine Phenol*, *Koffeinphenol*, *Coffeo-phenol*, *G.* $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot \text{C}_6\text{H}_5\text{O} + \text{H}_2\text{O}$.—Made by dissolving 22.6 parts of caffeine in 10 parts of fused phenol. It is in the form of a white or pinkish crystalline mass, soluble in water.

Caffeine Sulphate. *Caffeinæ Sulphas*, *Caffeinum Sulfuricum*, *Koffeinsulphat*, *Schwefelsaures Koffein*, *G.* $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2 \cdot \text{H}_2\text{SO}_4$.—The sulphate may be made by dissolving caffeine in alcohol, containing more sulphuric acid than is needed to make the salt, and setting the solution aside to crystallize. It is decomposed by alcohol or water alone. The salt contains about 66 per cent. of caffeine.

Cahinca. *David's Root*, *Radix Caihincæ*, *Cahinça*, *Fr.* *Kainkawurzel*, *G.*—This medicine attracted at one time considerable attention. The name of *cahinca* or *cainca* was adopted from the language of the Brazilian Indians. The Portuguese of Brazil call the medicine *raiz preta*, or *black root*. When first noticed in Europe, it was supposed to be derived from the *Chiococca racemosa* of Linnaeus, which was known to botanists as an inhabitant of the West Indies. But Martius, in his *Specimen Materiæ Medicæ Brasiliensis*, describes two other species of *Chiococca*, *C. anguifuga*, Mart., and *C. densifolia*, Mart., both of which are now known as *C. brachiata*, Ruiz and Pav., which afford roots having the properties of the root ascribed to *C. racemosa*. A. Richard, however, received from Brazil specimens of *C. racemosa* as the *cahinca* plant.

A specimen brought to Philadelphia consisted of cylindrical pieces, varying in size from the thickness of a straw to that of the little finger, somewhat bent or contorted, slightly wrinkled longitudinally, with occasional small asperities, internally ligneous, externally covered with a thin, brittle, reddish-brown bark, having a light brown or brownish ash-colored epidermis. The cortical portion, which was of a resinous character, had a bitter disagreeable taste, somewhat acrid and astringent; the ligneous part was quite tasteless. The virtues of the root reside almost exclusively in its bark. They are extracted by water and alcohol. *Cahinca* has been analyzed by several chemists. Four distinct principles were discovered in it by Pelletier and Caventou,—1, a crystallizable bitter substance, believed to be the active principle, and called *cahincic acid*, $\text{C}_{40}\text{H}_{64}\text{O}_{18}$; 2, a green fatty matter of a nauseous odor; 3, a yellow coloring matter; and 4, a colored viscid substance. Rochleder and Hlasiwetz found also caffe-tannic acid. By these chemists a tincture, obtained by boiling the bark in alcohol, was pre-

precipitated first with a spirituous solution of lead acetate, and afterwards, having been previously filtered, with the tribasic lead acetate. The first precipitate consisted chiefly of lead caffe-tannate and a portion of lead cahincate, the second of lead cahincate exclusively. Cahincic acid is white, without odor, of a taste at first scarcely perceptible, but afterwards extremely bitter and slightly astringent, slightly soluble in water, but readily soluble in alcohol, permanent in the air, and unaltered at 100° C. (212° F.). It reddens vegetable blues, and unites with the alkalis, but does not form crystallizable salts. It is thought to exist in the root as calcium subcahincate. When treated with diluted hydrochloric acid it is decomposed into glucose and other products, of which is obtained at first *chiococcic acid*, $C_{28}H_{48}O_7$ (thought by some to be identical with *quinovic acid*), and later, by boiling with alcoholic hydrochloric acid, *cahincetin*, $C_{22}H_{34}O_3$.

Cahinea is tonic, diuretic, purgative, emetic, and is capable of producing serious gastro-intestinal irritation. In Brazil it has long been used by the natives as a remedy for the bites of serpents. Patrick Brown speaks of the root of *C. racemosa* as very useful in obstinate rheumatism. It is said to be largely used for *dropsy* in Brazil, and Achille Richard, François, and other practitioners have attested its value. *Dose*, of the powdered bark, from twenty grains to a drachm (1.3–3.9 Gm.); of the aqueous or spirituous extract, from ten to twenty grains (0.65–1.3 Gm.).

Calamine. *Calamina. Lapis Calaminaris.* Calamine is the old name of the native zinc carbonate, although in mineralogy the name *calamine* is now applied to zinc silicate, while the name *Smithsonite* is given to the carbonate. It is found in the United States, as well as in Belgium, Germany, and England. It occurs in compact or earthy masses, or concretions, of a dull appearance, readily scratched by the knife, and breaking with an earthy fracture, or it occurs crystallized in rhombic forms. Its color is very variable, being, in different specimens, grayish, grayish-yellow, reddish-yellow, and, when very impure, brown- or brownish-yellow. Its sp. gr. varies from 3.4 to 4.4. Before the blow pipe it does not melt, but becomes yellow and sublimes. When of good quality, it is almost entirely soluble in the dilute mineral acids, and, unless it has been previously calcined, emits a few bubbles of carbon dioxide. If soluble in sulphuric acid, it can contain but little calcium carbonate and no barium sulphate.

Prepared Calamine. Calamina Præparata.—Calamine must be impalpable before being used in medicine. The following is the U. S. formula of 1850. "Take of Calamine a convenient quantity. Heat it to redness, and afterwards reduce it to a very fine powder." U. S. 1850. Prepared calamine occurs as a pinkish or flesh-colored powder, of an earthy appearance. Sometimes it is made up into small masses. It is used only externally as a mild astringent and desiccant in *excoriations* and *superficial ulcerations*, either as a dry powder dusted on the part, or as a cerate.

Calcium Acetate. *Calcii Acetas. Acétate de Chaux.* Fr. *Essigsaurer Kalk.* G. $Ca(C_2H_3O_2)_2 + H_2O$.—Made by neutralizing acetic acid with precipitated calcium carbonate, evaporating and crystallizing. Colorless needle-like crystals, soluble in water, less so in alcohol.

Calcium Benzoate. *Calcii Benzoas.* $Ca(C_7H_5O_2)_2 + 3H_2O$.—This salt may be made by adding

calcium carbonate to a hot aqueous solution of benzoic acid, filtering, and evaporating the solution, and collecting and drying the crystals, which usually form in beautiful radiating tufts. It is soluble in 18 parts of cold water and 6 parts of boiling water. *Calcium hippurate*, $Ca(C_9H_9NO_3)_2 + 3H_2O$, is made in a similar manner, and is identical in appearance and uses. Poulet recommends the latter highly in the *uric acid diathesis*, for *scrofula*, incipient *cirrhosis of the liver*, and in *struma*. *Dose*, ten grains (0.65 Gm.).

Calcium Borate. *Calcii Boras.* $Ca_3(BO_3)_2$. Calcium borate is prepared by mixing solutions of sodium borate and calcium chloride. It is a white, inodorous, tasteless powder. It is given internally in *diarrhœa*, and used externally as a deodorant and antiseptic.

Calcium Dithiocarbonate. *Dithio-Calcium Carbonate.* $CaCOS_2$.—An orange-red, crystalline, hygroscopic powder, slightly soluble in water, less so in alcohol. It has been especially employed by Tommasoli and Vicini (*Monatssch. f. Prakt. Dermatol.*, 1892) as a local application in *eczema*, *psoriasis*, *lupus*, *purulent venereal* and other skin diseases, in the form of a 5 per cent. ointment or a somewhat stronger aqueous solution. A 20 per cent. solution produced distinct burning irritation and even pustulation. Sabbatini states that the 1 per cent. solution inhibits, but does not kill pyogenic micro-organisms. On exposure, its aqueous solution undergoes decomposition with the separation of sulphur and hydrogen sulphide.

Calcium Glycero-arsenate. *Calcii Glycero-arsenas.*

A crumbling white powder which is insoluble in water and alcohol but freely dissolves in mineral and organic acids, especially in a dilute solution of citric acid. According to Schlagdenhaufen and Pagel, the lethal subcutaneous dose of this compound is for frogs, 19 grains (1.23 Gm.) per kilo (2½ lbs.), and that of guinea pigs, 47 grains (3.10 Gm.) per kilo (2½ lbs.). The preparation is therefore only slightly poisonous and has been employed in daily dose of one-sixth grain (0.01 Gm.) internally in *phthisis* by Spillmann and in *diabetes* by Heinrich Stern, with alleged good results, in doses of 4 to 10 grains (0.26–0.65 Gm.) to be taken three or four times daily.

Calcium Iodate. *Calcii Iodas.* $Ca(IO_3)_2 + 6H_2O$.—This is a white crystalline powder dissolving in about 400 parts of water. It contains 51 per cent. of iodine and 16 per cent. of available oxygen, which substances are liberated slowly in the presence of putrescent organic matters. It is stated further that in alkaline solution, while the organic matter is being oxidized by the oxygen set free from the decomposing iodate, the iodine slowly reforms iodates by the decomposition of water. The iodate so reformed, in contact with another portion of putrescible matter, yields further proportions of free oxygen and iodine to act as before, and so on. This salt was brought forward by E. Sonstadt as a valuable antiseptic, to be used in the preservation of food. (*Chem. News*, xxviii. 297; confirmed in *Provincial Med. Journ.*, March, 1890.) It is strongly recommended by W. Mackie (*L. L.*, 1900, No. 4035) as a substitute in surgery for iodoform and in internal medicine as a gastro-

intestinal antiseptic. The internal dose is from three to five grains (0.2–0.32 Gm.) given in capsules after meals.

Calcium Iodide. *Calcii Iodidum.* *Calcium Iodatum.* *Iodure de Calcium.* Fr. *Jodoalcium.* *Calcium Jodid.* G. CaI_2 .—According to Malem (B. G. T., Avril 30, 1868) this salt is preferable to any other iodine compound in *phthisis*. Malem prepares it by treating a solution of ferrous iodide with milk of lime. This liquor thus obtained, being filtered and evaporated, yields crystals of calcium iodide. It may also be made by dissolving lime or its carbonate in hydriodic acid. Pure calcium iodide is white, and crystallizes in large plates of a pearly lustre. Procured as recommended, it is yellowish, probably in consequence of the presence of iodine in excess. It is deliquescent, and very soluble in water, and its solution is capable of dissolving iodine added to it. Calcium iodide is much more unstable than potassium iodide. When taken into the stomach, it is rapidly decomposed into hydriodic acid and salts of lime, which are almost immediately absorbed. Most patients bear it very well. From one to three or four grains (0.065–0.2–0.26 Gm.) may be given after meals. (*Ann. Thér.*, 1869, 194.) To make the syrup of calcium iodide the following formula has been proposed by O. Eberbach (*P. J.*, 3d ser., i. 364). Take of iodine 4 oz.; iron (in form of wire) $7\frac{1}{2}$ dr.; distilled water q. s.; milk of lime (fresh) q. s.; sugar 28 oz.; simple syrup q. s.; mix 3 oz. of the iodine with the iron and 4 oz. of water, in a thin flask with long neck; shake occasionally until the reaction has ceased and the solution assumes a pale green color; filter the solution, and add the remainder of the iodine; heat to the boiling point, and add milk of lime until all of the iron is precipitated. Filter, and wash the precipitate with hot water until all the iodine is washed out, and then bring the whole to the measure of 20 fl. oz.; add the sugar, and dissolve by a gentle heat; to the solution add enough simple syrup to make it measure 40 fl. oz.; mix thoroughly, and fill into 2 oz. bottles, well corked.

Calcium Permanganate. *Calcii Permanganas.* CaMn_2O_8 .—This salt probably has the same physiological and medicinal properties as the corresponding salt of potassium. It has been used in *gastro-enteritis* and *diarrhœa* in doses of from one-half to one and a half grains (0.032–0.096 Gm.), but has been especially urged for the purification of water. For spring water twenty milligrammes, for river water forty milligrammes, per liter are recommended. If the color of the water becomes red the permanganate is indicated to be in excess.

Calcium Peroxide. *Calcii Peroxidum.* $\text{CaO}_2 + 4\text{H}_2\text{O}$.—A yellow crystalline powder which dissolves but sparingly in water. The solution has an alkaline reaction and possesses a somewhat caustic and astringent taste. In the presence of water calcium peroxide splits up into calcium hydroxide and oxygen. It has been brought forward as a powerful oxidizing antizymotic and as an antidote to hydrocyanic acid. In Hornstein's experiments it failed as an antidote unless the cyanide was given in very small quantities and the antidote was administered immediately after the poison. Its germicidal powers appear to be feeble, and its proneness to decomposition is a practical difficulty in its use. It has, however, been highly recommended by Reszkowski (*Gazette Lekarska*, 1899) in the summer diar-

rhœas of children, in doses of three to ten grains (0.2–0.65 Gm.), administered in milk. It is advised to keep it in parchment capsules in well stoppered bottles. Under the name of *calcium superoxide* or *gorite* a probably identical oxide has been put on the market. The germicidal influence of gorite was determined by Hornstein (*A. J. P.*, 1901, viii.) to be distinctly weaker than that of hydrogen dioxide; it was also found that if a rabbit, to which twice the fatal dose of potassium cyanide had been administered by the mouth, six to eight minutes later be given fifteen grains (1 Gm.) of gorite, injected into the stomach, no toxic symptoms follow. The chief value of the substance, according to Hornstein, is as a tooth-powder.

Calcium Salicylate. *Calcii Salicylas.* $\text{CaC}_7\text{H}_4\text{O}_3 + \text{H}_2\text{O}$.—This compound is the basic calcium salt. It is a sandy, white powder, almost insoluble in water. The neutral salt is also known and is quite soluble in water. Calcium salicylate has been used in Austria in doses of from seven to twenty grains (0.45 to 1.3 Gm.) for *diarrhœa* and *gastro-enteritis*. For method of preparation, see *P. J.*, vol. xxii. 1891.

Calcium Santonate.—This is a white, tasteless, insoluble powder, obtained by saturating hot milk of lime with santonin, and has been brought forward by Bombelen as superior to santonin as a vermifuge on account of its tastelessness, and especially because of its insolubility, which causes it to be absorbed with great slowness. (*Ap. Ztg.*, March, 1899.) Dose, one grain (0.065 Gm.).

Calcium Sulphophenate. *Calcii Sulphophenas.* *Calcium Sulphocarbonate.* *Karbonsulfosaures Calcium.* G. $[\text{C}_6\text{H}_4(\text{OH})\text{SO}_3]_2\text{Ca} + \text{H}_2\text{O}$.—Made by neutralizing paraphenolsulphonic acid with precipitated calcium carbonate. In the form of a colorless, almost odorless powder, astringent and bitter, readily soluble in water and alcohol. A 1 per cent. solution is recommended for internal administration as an antiseptic, disinfectant and astringent in doses of a fluidrachm (3.75 Cc.) every 3 hours.

Calcium Thiosulphate. *Calcii Thiosulphas.* *Calcium Sulphosulphate.* *Calcium Hyposulphite.* $\text{CaS}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$.—The following mode of preparing this salt is recommended by J. Laneau of Paris. Take 1000 parts of sulphur, 400 of lime, and 4000 of rain water; slake the lime with sufficient of the water, add the sulphur and the residue of the water, and boil for an hour and a half, adding water to keep up the measure; when cool filter the liquid through linen covered with filtering paper, and wash the residue with 1000 parts of water. A solution is thus obtained of calcium polysulphide of the sp. gr. 1.141. Into this pass a current of washed sulphurous acid gas until the solution becomes colorless; separate the precipitated sulphur (which may be used for the official precipitated sulphur); and evaporate the clear solution at a heat not exceeding 60°C . (140°F .), until it begins to crystallize, when it is to be set aside. The product is 700 parts of calcium thiosulphate. This is in six-sided crystals, which effloresce in a dry air. Laneau prepares a syrup of calcium thiosulphate by dissolving 10 parts of the crystallized salt in 20 parts of distilled water, and mixing with the solution 170 parts of syrup of orange flowers. (See *A. J. P.*, 1863, 223.) The dose of the salt is from ten to twenty grains (0.65–1.3 Gm.) three times a day, of the syrup from two to four fluidrachms (7.5–15 Cc.).

Of the *thiosulphates* (*hyposulphites*) generally, it may be said that they closely resemble the sulphites in medicinal properties, and may be employed as substitutes for those salts, over which they have the advantage of greater stability, passing less readily into sulphates on contact with the air. They may be prepared by boiling a sulphite or bisulphite for some time with sulphur. They are very soluble in water, and are recognized by the precipitation of sulphur when decomposed by an acid.

Cali Nuts.—These nuts, which come from the west coast of Africa, are the seeds of a papilionaceous plant, and have a more circular shape than Calabar beans, but otherwise agree with the latter in essential external characters. They contain an alkaloid which is said to be chemically and physiologically closely allied to physostigmine. (Merck, *Chem. Ob.*, 1887.)

Calotropis. *Br. Add. Mudar.*—The dried root-bark of *Calotropis procera*, R. Brown, and of *Calotropis gigantea*, R. Brown, freed from the outer corky layer. These asclepiadaceous plants are natives of Hindostan, but have become widely naturalized in various parts of the East and West Indies. Their milky juice is a violent local irritant, which, when taken internally, acts as an emetocathartic and may produce a fatal gastro-enteritis. In India it has long been used not only for suicidal purposes but to kill newly-born female infants, and is also applied to the womb to cause abortion.

The root-bark occurs in short more or less quilled pieces having a thickness of from one-tenth to one-fifth of an inch (two to five millimeters) and a width of not more than one and a half inches (thirty-seven millimeters). It is covered with a soft, grayish-buff, strongly furrowed and reticulated, easily separated periderm. The fracture is short and mealy; the taste bitter and acrid. According to C. J. H. Warden and L. A. Waddell, calotropis contains an acid resin, a crystalline colorless substance, *madaralban*, an amber-colored viscid body, *madarfluavil*, and caoutchouc. (*P. J.*, 1885, 165.)

Calotropis has been very largely used as a local remedy in Hindostan in *elephantiasis* and *leprosy*, and is asserted by John Morton (*Indian Medical Record*, viii. 1895) to act with extraordinary efficiency upon chronic *eczema*. It has also been employed internally as a remedy in *diarrhœa* and *dysentery*; also with less probability of usefulness in *syphilis* and *rheumatism*. Dose, of powder, from three to twelve grains (0.2–0.78 Gm.), three times a day, gradually increased until it affects the system.

Tincture of Calotropis. *Tinctura Calotropis, Br. Add.*, two ounces to a pint (alcohol 6 per cent.), is given in *doses* of one-half to one fluidrachm (1.8–3.75 Cc.).

Calycanthus. *Calycanthus glaucus*, Willd. (*Bulneria fertilis* (Walt.), Kearney, in Britton and Brown's *Flora*).—This is a shrub of the fam. Calycanthaceæ, from six to eight feet high, which inhabits the low, shady woods along the mountains of Georgia and North Carolina, and also Tennessee, where it is known as *sweet shrub* or *bubby*. According to R. G. Eccles, the seeds contain a fixed oil, and an alkaloid, *calycanthine*, of unknown physiological properties. H. W. Wiley (*A. J. P.*, 1890, 96) found in the seeds over 47 per cent. of oil and notable quantities of sugars (dextrose, sucrose, and dextrin), also 4.25 per cent. of alkaloid. This latter crystallizes from

ether in feathery crystals. The whole plant is aromatic, having, when crushed, the odor of strawberries.

Cam Wood.—A red dye-wood, procured from the *Baphia nitida*, Lodd, a leguminous tree, growing on the western coast of Africa. The wood is usually kept in the shops in the ground state. It yields its coloring matter scarcely at all to cold water, slightly to boiling water, and readily to alcohol and alkaline solutions. The coloring matter is thought to be identical with *santalum*, $C_{15}H_{14}O_5$.

Camphacollasis is the name given to the *camphoric acid ester of methylene diguaiacol*. It occurs in crystals, and is recommended as an antispasmodic, sedative and antiseptic in *doses* of 5 to 20 grains (0.32–1.3 Gm.).

Camphoroxol.—A compound of camphor with hydrogen dioxide. It forms a clear, colorless liquid with a fragrant odor of camphor.

Camphossil.—This is a crystalline, unctuous, deliquescent, tasteless mass, with a camphoraceous odor, insoluble in water. It is said to be a condensation product of camphor and salicylic acid, and as an antipyretic and antiseptic to be useful in *diarrhœas* in *doses* of eight grains (0.65 Gm.).

Canada Pitch. *Pin. Canadensis.* U. S. 1880. *Hemlock Pitch.*—The *Tsuga canadensis* (L.), Carr (*Pinus canadensis*, L., *Abies canadensis*, Michx.), *Hemlock* or *Hemlock Spruce* of the United States and Canada, when of full growth, is often seventy or eighty feet high, with a trunk two or three feet in diameter, and of nearly uniform dimensions for two-thirds of its length. The branches are slender, and dependent at their extremities. The leaves are very numerous, six or eight lines long, flat, denticulate, and irregularly arranged in two rows. The strobiles are ovate, little longer than the leaves, terminal and pendulous.

The tree is abundant in Canada, Nova Scotia, and the more northern parts of New England, and is found in the elevated and mountainous regions of the Middle States. Its bark is much used for tanning, an extract being made for the purpose. The tree contains much less juice than some other of the Pinaceæ, and very little flows from incisions made into its trunk. But in the trees which have attained their full growth, and are about to or have begun to decay, the juice exudes spontaneously, and hardens upon the bark, in consequence of the partial evaporation or oxidation of its volatile oil. The bark thus incrustated is stripped from the tree, broken into pieces, and boiled in water. The pitch melts, rises to the surface, is skimmed off, and is still further purified by a second boiling in water. Hemlock pitch is hard, brittle, quite opaque, of a dark reddish-brown color, becoming still darker by exposure to the air, of a weak peculiar odor, and scarcely any taste. It softens and becomes adhesive with a moderate heat, and even at ordinary temperatures takes the form of the vessel containing it, and melts at 92.2° C. (198° F.).

The constituents of this pitch are resin and a minute proportion of volatile oil. It is sometimes known by the incorrect name of *hemlock gum*. Canada pitch is a gentle rubefacient, closely analogous to Burgundy pitch in its properties, and employed for precisely the same purposes. It is, however, more readily softened by heat, and is sometimes almost too soft for convenient application at the temperature of the body. A volatile oil obtained from *Tsuga canadensis*, and called *oil of spruce* or *oil of hemlock*, has been employed to produce

abortion, with the effect of endangering the life of the woman. (J. S. Paige, *N. Y. M. J.*, viii. 184.)

W. Zinn (*M. M. W.*, Oct. 1902) reports a case of stupor and involuntary evacuation of urine, and collapse with subsequent psychic disturbance, as produced by the inhalation for many hours of the emanations from branches of *Pseudotsuga taxifolia* (Lamb.), Britton (*P. Douglasii*, Car.).

The U. S. Pharmacopœia of 1880 gave the following directions for preparing the *Hemlock or Canada Pitch Plaster* (*Emplastrum Picis Canadensis*, U. S. 1880): "Canada Pitch, ninety parts [or nine ounces av.]; Yellow Wax, ten parts [or one ounce av.], to make one hundred parts [or ten ounces av.]. Melt them together, strain the mixture, and stir constantly until it thickens on cooling." U. S. 1880.

Canary Seed. *Fructus (Semen) Canariense*. *Semence de Canarie*, Fr. *Kanariensamen*, G.—The seeds of *Phalaris canariensis*, L., an annual grass originally from the Canary Islands, but now growing wild in Europe and the United States. The seeds are ovate, somewhat compressed, about two lines long, shining, and of a light yellowish-gray color externally and brownish within. Their chief constituent is starch, and they are now used chiefly as a bird seed.

Canchalagua.—This plant, *Erythraea venusta*, A. Gray (Fam. Gentianaceæ), found on our Pacific coast, is a valuable bitter tonic and stomachic. (*Ph. Rec.*, 1887, 363.) *Erythraea australis*, R. Br., is said to be similarly used in Australia. (*P. J.*, xix.)

Canella.—The bark of *Canella alba*, Murray, was formerly recognized by the U. S. and Br. Pharmacopœias. The tree is a native of Florida and the Bahama and West India Islands. The bark of the branches, which is the part employed in medicine, is loosened and deprived of its epidermis by beating. After removal from the tree it is dried in the shade. It enters commerce solely from the Bahamas, where it is known as *cinnamon bark*, or as *white wood bark*. It occurs in pieces partially or completely quilled, occasionally somewhat twisted, of various sizes, from a few inches to two feet in length, from half a line to two or even three lines in thickness, and, in the quill, from half an inch to an inch and a half in diameter.

Canella is of a pale orange-yellow color externally, yellowish-white on the inner surface, with an aromatic odor somewhat resembling that of cloves, and a warm, bitterish, very pungent taste. It is brittle, breaking with a short fracture, and yielding, when pulverized, a yellowish-white powder. Boiling water extracts nearly one-fourth of its weight; but the infusion, though bitter, has comparatively little of the warmth and pungency of the bark. It yields all its virtues to alcohol, forming a bright yellow tincture, which is rendered milky by the addition of water. By distillation with water it affords a large proportion of a yellow or reddish, fragrant and very acrid volatile oil. It contains, moreover, according to the analysis of Petroz and Robinet, mannite, a peculiar very bitter extractive, resin, gum, starch, albumen, and various saline substances. Meyers and Reiche obtained twelve drachms of the volatile oil from ten pounds of the bark. They found it to consist of four different oils, the first being identical with the eugenol or eugenic acid of oil of cloves; the second is closely allied to the chief constituent of cajuput oil; the other oils require further examination. The bark yielded to Flück-

iger 0.74 per cent. of oil. Meyers and Reiche also obtained 8 per cent. of mannite and 6 per cent. of ash, chiefly calcium carbonate. Canella has been sometimes confounded with Winter's bark, from which, however, it differs widely. (See *Wintera*.) According to John P. Frey, it contains volatile oil, 1.28 per cent.; resin, 8.2 per cent.; mannite, 8 per cent.; ash, 8.9 per cent.; also starch, bitter principle, albumen, and cellulose. (*A. J. P.*, 1884, 1.) It is a mild, aromatic tonic, very acceptable to the stomach, and especially as an addition to tonic or purgative medicines. It is scarcely ever prescribed except in combination. In the West Indies it is employed by the negroes as a condiment and as an antiscorbutic. Dose, ten to forty grains (0.65 to 2.6 Gm.).

Cangourá.—An evergreen creeper, from the seeds of which the natives of Salvador are said to produce a paste which is a violent nerve poison, producing in some cases delirium lasting as long as eight days. (*Nouv. Rem.*, Avril, 1892.)

Caoutchouc, Artificial.—Within recent years many attempts have been made to make artificial rubber by the vulcanization of fatty oils with either sulphur or sulphur chloride. Linseed oil, cotton seed oil, and the fish oils have all been used for this purpose with varying success. Latterly it is asserted that very successful results have been attained by the vulcanization of maize oil. These products, known in Germany as *Factis*, may be white or dark colored, the latter color being obtained by the prolonged action of the sulphur. Oxidized or blown oils and sulphated oils are also used for the vulcanization. In 1894 Nobel patented solutions of nitrocellulose in heavy oil solvents as rubber substitutes for rubber varnishes and coatings. Much reclaimed rubber from old rubber articles is revulcanized and incorporated with pure rubber in the manufacture of new rubber articles.

Capparis. *Capparis spinosa*, L. *Caper-bush*. (Fam. Capparidaceæ).—A low, trailing shrub, growing in the south of Europe and north of Africa. The buds or unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acrid, burning taste, and is considered useful in *scurvy*. The dried bark of the root was formerly official. It is in pieces partially or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acrid, and aromatic taste. It contains *rutic acid* and a volatile substance of garlic-like odor. It is considered diuretic, and was formerly used in *amenorrhœa* and *chronic rheumatism*.

Capsella. *Capsella Bursa-pastoris*, Medic. *Shepherd's purse*. *Thlaspi Bursa-pastoris*, L. *Bursa-pastoris*, Weber. *Bursa Bursa-pastoris* (L.), Britt. *Bourse à Pasteur*, Molette, Fr. *Hirtentäschlein*, G. (Fam. Cruciferae).—This very common weed is bitter and pungent, yields on distillation a volatile oil identical with oil of mustard, and, according to E. Bombelon, contains an alkaloid, *bursine*. (See *A. J. P.*, 1888; also *Provincial Med. Journ.*, 1858.) It has been used as an antiscorbutic, also in *hæmaturia* and in other *hemorrhages*, *amenorrhœa* and *dropsy*. From two to four fluidounces (60–120 Cc.) of the fresh expressed juice may be given at a dose; or from one-fourth to one-half fluidrachm (0.9–1.8 Cc.) of the fluidextract of the dried plant.

Captol.—This proprietary preparation is said to be an impure condensation product of tannin

and hydrated chloral. It is a brown hygroscopic powder, slightly soluble in cold water, very soluble in hot water and alcohol, not altered by acids but decomposed by alkalies, striking an olive-green color with ferric salts. According to Eichhoff in *seborrhœa capitis* washing the head morning and evening with a 1 to 2 per cent. alcoholic solution of capul is very successful.

Capulincullo.—This drug, derived from the *Rhamnus humboldtianus* of Mexico, is said to be a violent poison, acting like curare. A non-toxic, non-drying fixed oil, tasteless and odorless, is obtained in considerable quantities from the fruit of the tree.

Carana. *Gum Carana.*—A resinous substance, in pieces of a blackish-gray color, externally dark brown, internally somewhat shining and translucent, brittle and pulverizable when dry, but, in the recent state, soft and adhesive, like pitch, easily fusible, of an agreeable balsamic odor when heated, and a bitterish resinous taste. (Geiger.) It is said to be derived from *Protium Carana* (H. B. K.), March (*Amyris Carana*, Humb.), a tree growing in Mexico and South America. Geiger refers it also to *Bursera Simaruba* (L.), Sarg. (*Bursera gummifera*, L.), of the West India Islands; but the resin of this tree is *resine de Gomari* or *resine de chibou* or *cachibou* of French writers, and is said to bear a close resemblance to the resin *tacamahac*. It is probable that in South America the name Carana is applied to different products. (A. J. P., xli. 233.)

Cardamine. *Cardamine pratensis*, L. *Cuckoo-flower.*—This is a perennial herbaceous plant, of the fam. Crucifera, with a simple, smooth, erect stem, about a foot in height. The plant grows in Northern Europe and America. Its bitterish and slightly pungent leaves are supposed to be antiscorbutic. The seeds are said to contain *myronic acid*, and to yield on decomposition by hydrolysis an oil analogous to oil of mustard. In Europe they are sometimes added to salads. The flowers have the same taste as the leaves, and, when fresh, a somewhat pungent odor. When dried they become inodorous and nearly insipid. They formerly possessed the reputation of being diuretic, and of being useful in *chorea* and *asthma*.

Carissin.—This is a glucoside which has been isolated from the bark of *Carissa* (*Carandas*) *ovata*, R. Br. (Fam. Apocynaceæ), by J. H. Maiden and H. G. Smith. It is stated to be exceedingly bitter and very poisonous, and in its chemical relations to resemble strophanthin, from which it differs, however, in being precipitated by basic acetate of lead and by tannic acid. Its most characteristic reaction is the production of a beautiful emerald-green color on the addition of a minute fragment of potassium dichromate to its solution in concentrated sulphuric acid. (P. J., 1896.)

Carnallite.—This mineral, found in Stassfurt, Prussia, is very extensively used in the preparation of potassium salts. It is a double magnesium and potassium chloride, associated with rock salt. (See P. J., March, 1872, 787.) The amount of carnallite mined is nearly two million tons annually. In 1904 the quantity of potash salts other than kainite was given as 2,179,471 tons, valued at about five million dollars.

Carnauba Root.—This root, the product of *Copernicia cerifera* (Ar.), Mart. (*Corypha cerifera*), the Brazilian wax palm, is several feet in length, about three-eighths of an inch thick, with a thick friable cortex of a fixed gray-

ish and reddish-brown color. (A. J. P., 1875, 349.) E. L. Cleaver found in it tannic acid, an acid resinous body, a red coloring matter, and a minute portion of volatile oil and of an alkaloid. (P. J., 1875, 965.) It is said to act like sarsaparilla. *Carnauba Wax*, with which the young leaves of the palm are coated, is used in church candles to prevent guttering, for the manufacture of phonograph records, in the composition of sealing wax and for other purposes in the arts.

Carota. U. S. 1870. *Carotte*, Fr. *Mohre*, Gelbe Rübe, G. *Daucus Carota*, L.—The wild carrot (Fam. Umbellifera) is widely distributed, growing along fences, and in neglected fields. It grows wild also in Europe. The well-known garden carrot is the same plant altered by cultivation. The seeds or fruits are very light, of a brownish color, an oval shape, flat on one side and convex on the other, and on their convex surface present four longitudinal ridges, to which stiff, whitish hairs or bristles are attached. They have an aromatic odor, and a warm, pungent, and bitterish taste. By distillation they yield a pale yellow volatile oil, upon which their virtues chiefly depend. The root of the wild plant may be substituted for the seeds. The root of the wild carrot is whitish, hard, coriaceous, branched, of a strong odor and an acid, disagreeable taste; that of the cultivated is reddish-orange, fleshy, thick, conical, rarely branched, of a pleasant odor, and a peculiar, sweet, mucilaginous taste. The constituents of the root are crystallizable and uncrystallizable sugar, a little starch, extractive, albumen, volatile oil, vegetable jelly or pectin, malic acid, saline matters, lignin, and a peculiar crystallizable, ruby red, neutral principle, without odor or taste, called *carotin*. According to Husemann, its formula is $C_{18}H_{24}O$. It forms reddish-brown, golden-green, lustrous quadratic crystals, fusing at $167.8^{\circ} C.$ ($334^{\circ} F.$), easily soluble in carbon disulphide, difficultly soluble in alcohol and ether, dissolving in concentrated sulphuric acid with violet or blue color, colored blue by sulphur dioxide. Husemann has also described a colorless compound, *hydrocarotin*, $C_{18}H_{30}O$, which exists with carotin in the juice of the carrot, and is probably changed into the latter by oxidation as the plant develops in growth. According to Frode and Seauer, carotin, as well as the modification which has been named hydrocarotin, is in fact cholesterol colored by a red pigment (A. J. P., 1866, 505), but Husemann seems to have disproved this assertion. Arnaud (C. R. A. S., cii. 1319), however, isolated cholesterol from carrots; this after repeated purifying with alcohol, was obtained crystallized in leaflets with 1 molecule of water. It melts at $136.5^{\circ} C.$ ($278^{\circ} F.$), losing the 1 molecule of water. It seems to be identical with the cholesterol obtained by Hesse from Calabar beans and from peas, and differs only very slightly from animal cholesterol. The substance called *vegetable jelly* was by some considered a modification of gum or mucilage, combined with a vegetable acid. Bracconnot found it to be a peculiar principle, and named it *pectin*, from the Greek (*πηκτός*), expressive of its characteristic property of gelatinizing. It exists more or less in all vegetables, and is abundant in certain fruits and roots from which jellies are prepared. It may be separated from the juice of fruits by alcohol, which precipitates it in the form of a jelly. This, being washed with weak alcohol and dried, yields a semi-transparent substance bearing some re-

semblance to ichthyocolla. Immersed in 100 parts of cold water, it swells like bassorin, and ultimately forms a homogeneous jelly. With a larger proportion of water it exhibits a mucilaginous consistence. It is less acted on by boiling than by cold water. When perfectly pure it is tasteless, and has no effect on vegetable blues. A striking peculiarity is that, by the agency of a fixed alkali or alkaline earthy base, it is instantly converted into pectic acid, which unites with the base to form a pectate. This may be decomposed by the addition of an acid, which unites with the base, and separates the pectic acid. Pectic acid thus obtained is in the form of a colorless jelly, slightly acidulous, with the property of reddening litmus paper, scarcely soluble in cold water, more soluble in boiling water, and forming with the latter a solution, which, though it does not become solid on cooling, is coagulated by alcohol, lime water, acids, or salts, and even by sugar if allowed to stand for some time. With the alkalies it forms salts, capable of gelatinizing; with the earths and metallic oxides, insoluble salts. Bracconot thinks that pectic acid exists in many plants already formed. Frémy found that pectin results, in fruits, from the reaction of acids upon a peculiar insoluble substance they contain when immature, called by him *pectose*, and that pectin is changed into pectic acid not only by alkalies, but also by vegetable albumen. Carrot seeds are slightly aromatic, moderately excitant and diuretic, and have been employed as a diuretic in chronic renal diseases and in dropsy. An ounce of them may be given in infusion, in a day. The flowers are sometimes substituted for the seeds, and the scraped root has been used as a local stimulant to sloughing or indolent ulcers.

Carthamus. *Carthamus tinctorius*, L. *Safflower*.—The African, false, American, or dyers' saffron is an annual composite, with a smooth, erect stem, somewhat branched at top, and a foot or two in height. The plant is a native of India, the Levant, and Egypt, and is cultivated in those countries, as well as in various parts of Europe and America. The florets are brought to us chiefly from the ports of the Mediterranean. *Safflower* (*Flores Carthami*; *Fleurs de carthame*, *Safran bâtard*, Fr.; *Saflor*, G.; *Cartamo*, It., Sp.) in mass is of a red color, diversified by the yellow of the styles contained within the floret. It has a peculiar slightly aromatic odor, and a scarcely perceptible bitterness. It contains a fixed oil; also two coloring substances,—one red, insoluble in alkaline liquids, and called *carthamin* or *carthamic acid* by Döbereiner, who found it to possess weak acid properties; the other yellow, and soluble in water. *Carthamin*, $C_{14}H_{16}O_7$, exists to the amount of from 0.3 to 0.6 per cent. only in the safflower, while the safflower-yellow, to which Malin gives the formula $C_{24}H_{30}O_{15}$, is present to the amount of from 24 to 30 per cent. It is the former which renders safflower useful as a dye stuff. These flowers are sometimes fraudulently mixed with saffron, which they resemble in color, but from which they may be distinguished by their tubular form, and the yellowish style and filaments which they enclose. In large doses *carthamus* is said to be laxative, and, administered in warm infusion, diaphoretic. It is used in domestic practice, as a substitute for saffron, in measles, scarlatina, and other exanthematous diseases, to promote the eruption. An infusion, two drachms to a pint of boiling water, is usually employed *pro re nata*.

Carubadi Guiden.—Under this name are largely used, for the relief of *asthma*, certain gall-like bodies, formed on various species of *Pistacia*, especially *P. Terebinthus*, L. (*P. Terebinthina*, St. Lag.), as the result of the stings of a hemipterous insect. According to Ignaz Hoffman, they are used by smoking and fumigation. For this purpose they are coarsely pulverized and burned in the bowl of a pipe, or in a dish, using a small funnel attached to a rubber tube for inhaling the fumes. Preparations should be made beforehand, so that the smoke may be inhaled at the commencement of the attack. They appear to act by exciting free secretion, probably through the turpentine with which they are saturated. They are said to be useful in chronic bronchitis. (S. Jb., Bd. cli.)

Carvacrol. *Isopropyl-o-cresol*. $C_{10}H_{13}OH$.—A phenol-like body existing in the essential oils of species of *Origanum* and some other labiate plants and made artificially from either carvone or camphor. It forms a thick oil which does not solidify at 25° C. (77° F.), boils at from 233° to 235° C. (451.4°–455° F.), and possesses powerful antiseptic properties.

Carvacrol Iodide.—*Iodocrol*, $C_{10}H_{13}OI$, is a bulky, grayish-yellow or buff-colored amorphous powder having a faint aromatic odor. It is insoluble in water, slightly soluble in alcohol, soluble in ether, chloroform, petroleum benzin, carbon disulphide, volatile and fixed oils. From its solution in ether and chloroform it is precipitated on the addition of alcohol, becoming paler in color. This purified product does not show signs of shrinkage until above 170° C. (338° F.), and at 200° C. (392° F.) becomes tarry and black. It is alleged that it combines the antiseptic properties of carvacrol with those of iodine, and possesses the advantage over iodoform in being odorless or nearly so, and in being five times as bulky. It has been used in surgical dressings in eczema, pruritus, chancres, and chancreoids.

Carya. *Hicoria*. *Hickory*.—Several species of the genus *Hicoria*, Raf. (*Carya*, Nuttall), grow in the United States, of which *H. Pecan* (Marsh.), Brit. (*H. olivæformis*, Raf. *C. olivæformis*, Nutt.), bears the pecan-nut of the Southwest, *H. ovata* (Mill.), Brit. (*C. alba*, Nutt.), the shell-bark nut, *H. laciniosa* (Michaux f.), Sarg. (*C. sulcata*, Nutt.), another variety of shell-bark and *H. alba* (L.) Brit., *Juglans alba*, L. (*C. tomentosa*, Nutt.), the common thick-shelled hickory nut. Other indigenous species are *H. minima* (Marsh.), Brit. (*C. amara*, Nutt.), *H. glabra* (Mill.), Brit. (*C. porcina*, Nutt.), and *H. microcarpa* (Nutt.), Raf. (*C. microcarpa*, Nutt.). The leaves of most if not all of these trees are somewhat aromatic and astringent, and the bark astringent and bitter. In the bark of *H. alba* F. R. Smith found a crystalline principle, *caryin*, which he believed to be *quercitrin*.

Cascara. *Cascara Amarga*. *Honduras bark*. The bark of an unidentified species of *Tariri* (*Picramnia*) (Fam. Simarubaceæ). It is a bitter tonic credited with specific alterative properties. For an elaborate discussion of the microscopic and chemical characters of the bark and its alkaloid *picramnine*, by Thompson, see *A. J. P.*, June, 1884.

Casearia. *Casearia esculenta*.—This Indian plant (Fam. Lamydaceæ) is said to be a valuable remedy in hepatic torpor, and to contain an organic acid allied to cathartic acid. (P. J., xx.)

Casein.—This substance is one of the important constituents of milk and cheese. It is now

made on a large scale in the United States from the "skim-milk" obtained from creameries; this is conducted into tanks and heated by steam to 120° F., then coagulated by hydrochloric acid and thoroughly agitated; the casein separates into a mass, and the remaining liquid is used in the manufacture of sugar of milk. See *Saccharum Lactis* and a paper by C. H. LaWall in the *Alumni Report of the Philadelphia College of Pharmacy*, April, 1902. Also an excellent paper by J. W. England on the manufacture and uses of casein in the *Proc. A. Ph. A.*, 1902, p. 357. It has been proposed by Seger as an emulsifying agent in pharmacy. One gallon of milk is treated with two and a half fluidounces of water of ammonia for twenty-four hours, and, after removing the saponaceous matter from the surface of the mixture, the serum is precipitated with acetic acid. The magma of casein, strongly pressed, is treated with sodium bicarbonate, and with a sufficient quantity of sugar to make the dried product contain one-tenth of its weight of casein. The powdered substance dissolves easily in water, and, mixed with its weight of gum, may be used for almost all of the emulsions. Resinous matters and balsams previously dissolved in alcohol, essences, and oils, may be mixed with it in the bottle itself without using the mortar. The only defect in this casein saccharate is its slight odor. (*L'Union Pharm.*, May, 1887.)

Casimiroa. *Casimiroa edulis*. Llav. and Lex. *Zapote blanco*. *Cochilsapote*. *White Sapota*.—This is a large tree belonging to the family of Aurantiaceæ, a native of Mexico, the leaves are employed in *diarrhæa* and as an anthelmintic. The seeds are said to be narcotic. In them José Sanchez (*Breve estudio Zabote blanco*, Thesis, Mexico, 1893) has found a resin and a crystalline alkaloidal body. Bikorn (*A. Pharm.*, 241, p. 166) asserts that the base, for which he suggests the name *casimirose*, is glucosidal in nature and assigns the formula $C_{30}H_{52}N_2O_8$.

Cassia. *Cassia marylandica*, L. *Séné Américain*, Fr. *Amerikanische Senna*, G. (Fam. Leguminosæ.)—*American senna* is an indigenous perennial plant of vigorous growth, sending up annually numerous round, erect, nearly smooth stems, which are usually simple, and rise from three to six feet in height. The leaves are alternate, and composed of from eight to ten pairs of oblong-lanceolate, smooth, mucronate leaflets, green on their upper surface, pale beneath, and connected by short petioles with the common footstalk, which is compressed, channelled above, and furnished near its base with an ovate, stipitate gland. The flowers, which are of a beautiful golden-yellow color, grow in short axillary racemes at the upper part of the stem. The calyx is composed of five oval, obtuse, unequal yellow sepals; the corolla of the same number of spatulate, concave petals, of which three are ascending, and two descending and larger than the others. The stamens are ten, with yellow filaments and brown anthers, which open by a terminal pore. The three upper stamens bear short abortive anthers; the three lowermost are long, curved, and tapering into a beak. The ovary bears an erect style terminating in a hairy stigma. The fruit is a pendulous legume, from two to four inches long, linear, curved, swelling at the seeds, somewhat hairy, and of a blackish color. The *American senna*, or *wild senna*, is very common in all parts of the Eastern United States south of New York. The leaves, which should be collected in

August or the beginning of September, are sometimes brought into the market, compressed into oblong cakes, like those prepared by the Shakers from most herbaceous medicinal plants. The leaflets are from an inch and a half to two inches long, from one-fourth to half an inch in breadth, thin, pliable, and of a pale green color. They have a feeble odor, and a nauseous taste, somewhat analogous to that of senna. Water and alcohol extract their virtues. Hermann J. M. Schroeter (*A. J. P.*, 1888, 231) found in them a yellow coloring matter identical with *chrysophanic acid*; also an active principle corresponding in all respects with *cathartic acid*. For earlier analysis by Martin, see *A. J. P.*, i. 22. American senna is an efficient and safe cathartic, acting like senna but more feebly.

Cassia nictitans, L., was investigated by Gallaher (*A. J. P.*, 1888, 280), who failed to find any glucoside or alkaloid. The amount of volatile oil found was very small, and cathartic acid could not be prepared from it, although the powder produced griping. The leaves of *Cassia alata*, L., are recommended by Conillebault in *ringworm*; they are moistened and the parts affected rubbed with them. (*A. J. P.*, 1887, 266.)

Under the names of *Cheshmat*, *Chashmizok*, *Schischen*, the seeds of *C. absus*, L., are said to be used in India and Africa in the treatment of inflammations of the eye, either in the form of a fine powder or an infusion made from the coarsely ground seeds to which several medicinal substances are added.

The root of the *Cassia beareana* is said to be very useful in the so-called *black-water fever* of Africa. (See *P. J.*, vols. xlvii., xlviii.)

Castanea. *U. S.* 1890. *Chestnut*.—Under this name the U. S. Pharmacopœia formerly recognized the leaves of *Castanea dentata* (Marshall), Borkh., collected in September or October while still green. Of the few species included in the genus *Castanea*, two are natives of North America. Of these *C. dentata* has been considered by many botanists as identical with *C. sativa*, Mill. (*C. vesca*, Gaertn.), of Europe and was described by Michaux as a variety of that species under the name of *americana*. Botanists at present, however, generally consider the two species as distinct. The fruit of the *European chestnut*, or, as it is commonly called in the United States, *Spanish chestnut*, differs greatly from the *American chestnut* both in size and shape. Further, the European tree when planted in America does not lose its distinctive characteristics. The leaves of the European chestnut are more erect and less deeply serrate than those of the American, and usually have a rounded or heart-shaped base, whereas the base of the American leaf is commonly somewhat pointed. Again, the European leaf is commonly stellately tomentose on the under surface, at least when young. *Castanea* leaves are from four to ten inches long by about two inches in breadth, oblong-elliptical, sharp at the ends, strongly and somewhat unequally serrated with prominent parallel nerves beneath, of a bright color, and so flexible and tenacious as to be powdered with difficulty. It is almost impossible to exhaust them by percolation. Their odor is feeble and their taste slightly astringent. They yield their virtues freely to water, and probably less so to alcohol. John B. Turner found in chestnut leaves chlorophyll, tannin, gallic acid, gum, and albumen. (*A. J. P.*, 1879, p. 542.) In addition to these constituents, L. J. Steltzer found

potassium, calcium, magnesium, and iron carbonates, chlorides, and phosphates, and a trace of resin and fat. (*A. J. P.*, 1880, p. 294.)

Castanea leaves, as proposed by J. C. Close in 1862, have been used to some extent in *whooping cough*, but the possession by them of any physiological or medicinal power is extremely doubtful and they have passed out of use. They are best administered in the form of a *fluidextract*.

Extractum Castaneæ Fluidum. U. S. 1890. *Fluid Extract of Castanea*.—"Castanea, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Glycerin, one hundred cubic centimeters [or 3 fluidounces, 183 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Pour five thousand cubic centimeters [or 169 fluidounces, 33 minims] of boiling Water upon the powder, allow it to macerate for two hours, then express the liquid, transfer the residue to a percolator, and pour Water upon it until the powder is exhausted. Evaporate the united liquids, on a water-bath, to two thousand cubic centimeters [or 67 fluidounces, 5 fluidrachms], allow this to cool, and add six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol. When the insoluble matter has subsided, separate the clear liquid, filter the remainder, evaporate the united liquids to seven hundred cubic centimeters [or 23 fluidounces, 321 minims], allow this to cool, add the Glycerin, and enough Alcohol to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890. The preparation is an aqueous fluidextract with only sufficient alcohol to preserve it. It is a thick reddish-brown liquid, having an astringent taste. Dose, from one to two fluidrachms (3.75 to 7.5 Cc.).

Castanea pumila (L.), Mill., *Chinquapin* of the Southern United States, is a bush or small tree usually eight or ten feet in height, but in the Gulf States reaches sometimes thirty feet. The oblong, acute, mucronately serrated leaves are readily distinguished from those of the ordinary chestnut by being whitish and downy underneath. The bark has been used as an astringent tonic. (For analysis, see *A. J. P.*, 1899.)

Castela. *Castela Nicholsonii*, Hook. (Fam. Simarubaceæ).—This plant is reputed to have antiseptic properties, probably due to a resinous principle discovered by J. L. Putegnat and named by him *amargosin*. (See *N. R.*, April, 1883.)

Castor. *Castoreum*, *Castoréum*, Fr. *Bibergeil*, G. *Castoro*, It. *Castoreo*, Sp.—In the beaver, *Castor fiber*, L., between the anus and external genitals of both sexes, are two pairs of membranous follicles, of which the lower and larger are pear shaped, and contain an oily, viscid, highly odorous substance, secreted by glands which lie externally to the sac. After death, the follicles containing castor are removed, and dried either by smoke or in the sun.

This drug is derived either from the northern and northwestern parts of America, or from Russia, and is called in commerce, according to its source, Canadian or American and Russian castor. It is supposed by some that the American and Russian beavers are distinct species, the former being a building, the latter a burrowing animal, and additional ground for the supposition is afforded by the fact that the products of the two differ considerably. Of the Russian castor only a very small portion is imported into this country.

Castor comes to us in the form of solid unctuous masses, contained in sacs about two inches in length, larger at one end than at the other, much flattened and wrinkled, of a brown or blackish color externally, and united in pairs by the excretory ducts which connect them in the living animal. In each pair one sac is generally larger than the other. They are divided internally into numerous cells, containing the castor, which, when the sacs are cut or torn open, is exhibited of a brown or reddish-brown color, intermingled more or less with the whitish membrane forming the cells. Those brought from Russia are larger, fuller, heavier, and less tenacious than the American; and their contents, which are of a rusty or liver color, have a stronger taste and odor, and are considered more valuable as a medicine. A variety of Russian castor, described by Pereira under the name of *chalky Russian castor*, is in smaller and rounder sacs than the American, has a peculiar empyreumatic odor very different from that of the other varieties, breaks like starch under the teeth, and is characterized by effervescing with diluted hydrochloric acid. Müller found 40.646 per cent. of calcium carbonate. According to Kohli, Canadian castor, treated with distilled water and ammonia, affords an orange precipitate, while the precipitate thrown down from the Russian under similar treatment is white.

Good castor has a strong, fetid, peculiar odor; a bitter, acrid, and nauseous taste, and a color more or less tinged with red. It is of a softer or harder consistence according as it is more or less thoroughly dried. When perfectly desiccated, though still slightly unctuous, it is hard, brittle, and has a resinous fracture. Its chemical constituents, according to Brandes, are volatile oil; a resinous matter; albumin; a substance resembling *osmazome*; mucus; calcium urate, carbonate, benzoate, phosphate, and sulphate; sodium acetate and chloride; potassium chloride, sulphate, and benzoate; ammonium carbonate; membranous matter, and a peculiar proximate principle discovered by Bizio, an Italian chemist, and called by him *castorin*. This principle crystallizes in long, diaphanous, fasciculated prisms, has the odor of castor, and a copperish taste. It is insoluble in cold water and cold alcohol, but is dissolved in 100 parts of the latter liquid at the boiling temperature, and by the essential oils. It possesses neither alkaline nor acid properties, and is considered as belonging to the cholesterin group of bodies. It may be obtained by treating castor, minutely divided, with six times its weight of boiling alcohol, filtering the liquor while hot, and allowing it to cool. The *castorin* is slowly deposited, and may be purified by means of cold alcohol.

Valenciennes, who could not obtain the crystals white and pure by simple treatment with alcohol, succeeded by first boiling together a mixture of equal parts of castor and lime water, and acting upon the residue, separated and dried, with boiling alcohol of the sp. gr. 0.823. Canadian castor is said to yield 1.98 per cent., and Russian castor 4.60 per cent., of *castorin*. This, together with the volatile oil and the peculiar resin, are said to constitute the medicinal principles. (Pennetier, *Matières Premières Organiques*, 783.) The volatile oil may be obtained by repeated distillation with the same portion of water. It is pale yellow, and has the odor and taste of castor.

F. Wöhler ascertained the existence of salicin and of phenol in a specimen of castor; Pereira detected *salicylic aldehyde* (oil of *Spiræa ulmaria*) in castor, and concluded that the oil of castor had been converted into that principle. (P. J., xi. 200.) The salicin of the castor, however, probably proceeds from the willow and poplar on which the beaver feeds.

Alcohol and ether extract the virtues of castor. An infusion made with boiling water has its sensible properties in a slight degree, but the odorous principle of the drug is dissipated by decoction. The virtues of castor are impaired by age. Warmth, and especially moisture, promote its decomposition. In a dry cool place it may be kept for a long time without material deterioration. When quite black, with little taste or odor, it is unfit for use. The castor follicles are sometimes partly deprived of the castor, and its place supplied with sawdust. A factitious preparation has been sold, consisting of a mixture of various drugs, scented with genuine castor, intermingled with membrane, and stuffed into the scrotum of a goat. The fraud may be detected by the comparatively feeble odor, the absence of other characteristic, sensible properties, and the want of the smaller follicles containing fatty matter, often attached to the bags of castor.

Castor was at one time much used as a stimulant antispasmodic, also as an emmenagogue, but has passed almost entirely out of vogue. It may be given in *hysterical affections* in doses of ten to thirty grains (0.65–2.0 Gm.), in capsules or emulsion.

A substance allied to castor is the secretion of the anal glands, used for the purpose of defence by the *Mephitis mephitis*, or common *skunk* of North America. According to T. B. Aldrich, this is a neutral, golden-colored liquid, having an extremely penetrating and not altogether agreeable odor, containing mercaptan, allyl-sulphide, and traces of butyl-mercaptan. (C. D., 1897.)

Catalpa. *Catalpa bignonioides*, Walt. *Bignonia Catalpa*, L. *Catalpa Catalpa*, (L.) Karst. *Catalpa-tree*, or *Catauba-tree*.—This is a beautiful indigenous, flowering tree, of the fam. Bignoniaceæ, the seeds of which have been employed in *asthma*. Eugene O. Rau obtained from them tannin and a bitter crystalline principle. (A. J. P., xlii. 204.) F. K. Brown obtained from the seeds resin, fixed oil, tannin, sugar, and two crystalline bodies, their exact nature not being determined. (A. J. P., 1887, 230.) I. Schneck states that large doses cause nausea, vomiting, and slow, weak, intermittent pulse. He gave two fluidrachms (7.5 Cc.) of tincture (1 oz. troy to 1 pint) every one to three hours.

Cataplasms. *Cataplasmata*. *Poultices*. *Cataplasmes*, Fr. *Umschläge*, *Breiümschläge*, G.—Cataplasms, or poultices, are moist substances intended for external application, of such a consistence as to accommodate themselves accurately to the surface to which they are applied, without being so liquid as to spread over the neighboring parts, or so tenacious as to adhere firmly to the skin. As they are in this country seldom made by the apothecary, with the exception of cataplasm of kaolin, they were not deemed by the compilers of the U. S. Pharmacopœia proper objects for official direction.

Cataria. *Nepeta Cataria*, L. *Catnep* or *catmint*. *Cataire*, Fr. *Katzenminze*, G. *Cataire*, It. *Gatera*, Sp.—Catnep is a perennial labiate plant which is abundant in the United States, but

is supposed to have been introduced from Europe. The whole herb is used; it has a strong, peculiar, rather disagreeable odor, and a pungent, aromatic, bitterish, camphorous taste. The active constituents are volatile oil, and tannin of the kind which produces a greenish color with the salts of iron. Therapeutically it is a very feeble mint.

Catechu. U. S. 1890. *Catechu Nigrum*, Br. Add. *Cutch*, *Cachou*, Fr. *Pegu Katchu*, G. *Caticu*, *Catto*, It. *Catecu*, Sp. *Cutt*, Hindostanee.

The U. S. P. (8th Rev.) dismissed catechu and introduced gambir because of the greater uniformity in quality of the latter. See *Gambir*, p. 574.

The U. S. P. 1890 defined catechu as "an extract prepared from the wood of *Acacia Catechu* (Linné fil.) Willdenow (nat. ord. *Leguminosæ*)."

Acacia Catechu. Willd., *Sp. Plant.*, iv. 1079. According to Kerr, whose description has been followed by most subsequent writers, *Acacia Catechu* is a small tree, seldom more than twelve feet in height, with a trunk one foot in diameter, dividing towards the top into many close branches, and covered with a thick, rough, brown bark. This species of *Acacia* is a native of the East Indies, growing abundantly in various provinces of Hindostan, and in the Burmese Empire. Pereira says that it is common in Jamaica.

This drug had been long known before its source was discovered. It was at first called *Terra japonica*, under the erroneous impression that it was an earthy substance derived from Japan. When ascertained by analysis to be of vegetable origin, it was generally considered by writers on the *Materia Medica* to be an extract of the *betel nut*. Its true origin was made known by Kerr, assistant surgeon of the civil hospital in Bengal. According to Kerr, the manufacturer, having cut off the exterior white part of the wood, reduces the interior brown or reddish-colored portion into chips, which he then boils in water in unglazed earthen vessels until all the soluble matter is dissolved. The decoction thus obtained is evaporated first by artificial heat, and afterward in the sun, until it has assumed a thick consistence, when it is spread out to dry upon a mat or cloth, being, while yet soft, divided by means of a string into square or quadrangular pieces. The account subsequently given by Royle, of the preparation of the extract in Northern India, is essentially the same. The process, as he observed it, was completed by the pouring of the extract into quadrangular earthen moulds. It is said that the unripe fruit and leaves are also sometimes submitted to decoction. Three colors of catechu are prepared; the light red or red, which is considered best and is especially employed in Burmah and India to chew with the betel nut; the dark red and black, which are made especially for European and American markets, and which are apt to suffer adulteration *en route* in China.

The name *catechu* in the native language signifies the *juice of a tree*, and appears to have been applied to astringent extracts obtained from various plants. Commerce is chiefly supplied with catechu from Bahar, Northern India, and Nepaul through Calcutta, from Canara through Bombay, and from the Burmese dominions. It is frequently called *cutch* by the English traders, a name derived from the Hindostanee word *cutt*. The following varieties are or have been found in the Philadelphia markets.

Plano-convex Catechu. *Cake Catechu*.—This is in the form of circular cakes, flat on one side, con-

vex on the other, and usually somewhat rounded at the edge, as if the soft extract had been placed in saucers, or vessels of a similar shape, to harden. As found in the retail shops, it is generally in fragments, most of which, however, exhibit some evidences of the original form. The cakes are of various sizes, from two or three to six inches or more in diameter and weighing from a few ounces to nearly two pounds. Their exterior is usually smooth and dark brown, but we have seen a specimen in which the flat surface exhibited impressions as if produced by coarse matting. The color internally is always brown, sometimes of a light yellowish-brown or chocolate color, but more frequently dark reddish-brown, and sometimes almost black. The cakes are almost always more or less cellular in their interior; but in this respect great diversity exists. Sometimes they are very porous, so as almost to present a spongy appearance, sometimes compact and nearly uniform, and this difference may be observed even in the same piece. The fracture is sometimes rough and dull, but in the more compact parts is usually smooth and somewhat shining, and occasionally a piece split in one direction will exhibit a spongy fracture, while in another it will be shining and resinous, indicating the consolidation of the extract in layers. This variety of catechu is often of good quality.

Pegu Catechu.—This is the product derived from the Burmese dominions, and named from that section of the country whence it is exported. It enters commerce, probably in general through Calcutta, in large masses, sometimes of one cwt., consisting of layers of flat cakes, each wrapped in leaves, said to be those of the *Mitragyna parvifolia*, Korth. (*Stephegyua diversifolia*, Benth. and Hook. *Nauclea brunonis*, Wall. Cat.) In this form, however, we do not see it in the shops, but almost always in angular, irregular fragments, in which portions of two layers sometimes cohere with leaves between them, indicating their origin. It is characterized by its compactness, shining fracture, and blackish-brown or dark port-wine color, so that when finally broken it bears considerable resemblance to kino. This is an excellent variety of catechu.

Catechu in Quadrangular Cakes.—This is scarcely ever found in commerce in its complete form, and the fragments are often such that it would be impossible to infer from them the original shape of the cake. This is usually between two and three inches in length and breadth, and somewhat less in thickness, of a rusty-brown color externally, and dark brown or brownish gray within with a somewhat rough and dull fracture, but, when broken across the layers in which it is sometimes disposed, exhibiting a smoother and more shining surface. Guibourt speaks of the layers as being blackish externally and grayish within, and bearing some resemblance to the bark of a tree, a resemblance, however, which has not struck us in the specimens which have fallen under our notice. There is little doubt that this variety comes from the provinces of Bahar and Northern India, where the preparation of the drug was witnessed by Kerr and Royle, each of whom speak of it as being brought, when drying, into the quadrangular form. It has been called *Bengal catechu*.

Pale catechu, so far as the term is not applied to gambir, may be considered as belonging to this variety. A specimen with this name, which was sent from India to the London exhibition of 1862, and which G. B. Wood had an opportunity of examining, was in oblong rectangular pieces, or

fragments of such pieces, about three and a half inches long by an inch and a half in breadth, of a dirty yellowish color within, and an earthy fracture, quite free from gloss, and bearing a very much stronger resemblance to gambir than to catechu.

Catechu in Balls.—We have seen this in two forms—one consisting of globular balls about as large as an orange, very hard and heavy, of a ferruginous aspect externally, very rough when broken, and so full of sand as to be gritty under the teeth; the other in cakes, originally, in all probability, globular, and of about the same dimensions, but flattened and otherwise pressed out of shape before being perfectly dried, sometimes two adhering together, and closely resembling in external and internal color, and in the character of their fracture, the quadrangular variety last described. The former kind is rare, and the specimens we have seen had been twenty years in the shop, and had very much the appearance of a factitious product. The latter is in all probability the kind known formerly as the *Bombay catechu*, as Hamilton, and, more recently Mackintosh, in describing the mode of preparing catechu on the Malabar coast, of which Bombay is the entrepôt, say that, while the extract is soft, it is shaped into balls about the size of an orange.

Guibourt and Pereira describe other varieties, which we have not met with, and which are probably rare. One of these is the *Siam catechu*, in conical masses shaped like a betel nut and weighing about a pound and a half. Its fracture is shining and liver-colored, like that of hepatic aloes; in other respects it resembles Pegu catechu. Another is the *black mucilaginous catechu* of Guibourt, in parallelipeds an inch and a half in length by an inch in breadth. Internally it is black and shining, and its taste is mucilaginous and feebly astringent. A third is the *dull reddish catechu* of Guibourt, in somewhat flattened balls, weighing three or four ounces, of a dull reddish, wavy, and often marbled fracture. Many years since, an extract like this was brought to Philadelphia upon speculation by a merchant from Calcutta, but it is not now in the market. Lastly, there is a *pale or whitish catechu*, in small roundish or oval lumps, with an irregular surface, dark or blackish brown externally, very pale and dull internally, and of a bitter, astringent and sweetish taste, with a smoky flavor. It is unknown in commerce.

Areca Catechu.—This is obtained from the Areca Nut Palm. (See *Areca Nut*, page 1395.) It is prepared by boiling the nuts in water and evaporating the decoction. There are two varieties; one of a black color, very astringent, mixed with paddy husks and other impurities, and obtained by evaporating the first decoction, the other, yellowish-brown, of an earthy fracture, and pure, resulting from the evaporation of a decoction of the nuts which had been submitted to the previous boiling. The first is called *kassu*, the other *coury*. (Heyne, *Tracts, etc., on India*.) They are prepared in Mysore, and Ainslie states that both varieties are sold in the bazaars of Lower India, and used for the same purpose as the official catechu. They are also much used for chewing by the natives. But they are seldom exported, and it is uncertain whether they find their way into European or American commerce. Pereira thought he had identified the *kassu* with a variety of catechu derived from Ceylon, where

he had been informed that an extract of the areca nut is prepared. It was in circular flat cakes, from two to three inches in diameter, scarcely an inch thick, covered on one side with paddy husks, and internally blackish-brown and shining.

Catechu is inodorous, with an astringent and bitter taste, followed by a sense of sweetness. It is brittle, and breaks with a fracture which is rough in some specimens, in others uniform, resinous, and shining. That which is preferred in our market is of a dark color, easily broken into small angular fragments, with a smooth glossy surface, bearing some resemblance to kino. Catechu is often mixed with sand, sticks, and other impurities. The U. S. P. 1890 gave the following tests of purity. "In irregular masses, containing fragments of leaves, dark brown, brittle, somewhat porous and glossy when freshly broken. It is nearly inodorous, and has a strongly astringent and sweetish taste. If a portion of Catechu be digested with 10 times its weight of alcohol, and the liquid filtered, the undissolved matter, after being dried at 100° C. (212° F.), should not exceed 15 per cent. of the original weight. The tincture, diluted with 100 parts of water, acquires a green color on the addition of ferric chloride test-solution. If two parts of Catechu be boiled with 20 parts of water, a brownish-red, turbid liquid will be obtained which turns blue litmus paper red. Upon incineration, Catechu should not leave more than 6 per cent. of ash." U. S. 1890.

The proportion of tannic acid, which may be considered the efficient principle, varies from about 45 to 55 per cent. in catechu or cutch, and from 36 to 40 per cent. in gambir. The portion designated by Davy as extractive is said to contain, if it does not chiefly consist, of a principle discovered by Buchner, and now called *catechin*, *catechuin*, or *catechuic acid*, to which Etti gives the formula $C_{18}H_{18}O_8$. To prepare pure catechin, Etti recommends the following process: Catechu is dissolved in eight times its weight of boiling water, and the liquid, after being strained through a cloth, is left for some days until the insoluble catechin has subsided. The crude catechin is collected in a linen cloth and submitted to the action of a screw press, then dissolved in a sufficient amount of diluted alcohol, and the filtered solution is shaken up with ether as long as any catechin is thereby dissolved, and after the ether has been removed by distillation the residue is taken up with distilled water, and the solution is left for a few days, when the catechin crystallizes out in an almost colorless state. After pressure in a cloth it is again dissolved in boiling water, when a yellowish-white body remains behind, which appears to be *quercetin*. The deep red liquid remaining behind after the catechin has been dissolved out with ether contains *catechu red*, $C_{36}H_{34}O_{15}$, which is evidently the first anhydride of catechin. The *tannic acid* is of the variety which precipitates iron of a greenish-black color, and differs from most of the other varieties in not yielding grape sugar when digested with diluted sulphuric acid. It is not, therefore, a glucoside. It precipitates gelatin, but not tartar emetic (Kane), and is not, like the tannic acid exposure of galls, converted into gallic acid by the access of the air. It may be distinguished by the name of *catechu-tannic acid*. Catechu is almost wholly soluble in a large quantity of water, to which it imparts a brown color. The extractive or catechuic acid is much less soluble than the astringent principle, which may be almost entirely separated

from it by the frequent application of small quantities of cold water. Boiling water dissolves it much more readily than cold, and deposits it of a reddish-brown color upon cooling. Both principles are readily dissolved by alcohol or proof spirit, and also by ether.

The importations of *cutch* or catechu and Terra japonica or gambir for purposes of tanning and calico printing are quite large, being in 1905, for cutch 3,986,886 lbs., valued at \$163,359, and for gambir 32,192,891 lbs., valued at \$1,112,660. De Meyer affirms that the best method of detecting adulteration of catechu is to treat the suspected drug with ether. Catechu of good quality, after repeated treatment with ether, loses 53 per cent. of its weight, and the dried residue weighs only 47 per cent. of the catechu employed. If this be exceeded, the drug must be proportionately impure. (J. P. C., Juin, 1870, 479.) A. Jossart (J. P. A., 1881, 41) examined a catechu which was adulterated with from 60 to 65 per cent. of ferrous carbonate. For methods of assaying catechu and gambir, see Trimble's *The Tannins*, 43; also *Ph. Rev.*, 1897, 27. (See also *Gambir*, p. 574.)

Catha. *Catha edulis*.—Under various Arabic names, such as *Kât*, *Khât*, *Chaat*, *Kus es Salahin*, *Tchaad*, *Tschut*, *Tohat*, *Tohat*, *Gât*, the leaves of *Catha edulis*, Forsk. (Fam. Celastraceæ) (*Abyssinian* or *African tea*), are very largely used as a stimulant in Northern Africa, the plant being extensively cultivated. According to Collin, from 1400 to 1500 camel loads are yearly sold in Aden. The plant is a shrub, reaching the height of 9 to 12 feet, with thin coriaceous leaves whose margin is bluntly serrate. The rounded, grayish-green twigs are, for commercial purposes, dried with the leaves and tied together in bundles containing about forty twigs; the bundles are commonly from twelve to fourteen inches in length and three to four inches in diameter, but sometimes much smaller. The leaves are chewed both green and fresh, and are in some places made into a tea. Their taste is said to resemble that of coca, and the inebriation which they produce in the Arabs is described as similar to that caused by coca in the South American natives.

So far as known *Catha* is not used as a medicine in Africa, but it has been employed to some extent as a stimulant in Europe in *neurasthenia*, *migraine*, and allied conditions. Bernon concluded that there is no alkaloid in it. Flückiger and Gerock isolated a volatile liquid, which they believe to be an alkaloid, and to which they gave the name of *katine*. In 1897 T. Shennan (*Royal Coll. Phys. Lab. Rep.*, vi. 1897) obtained evidences of the existence of a non-volatile alkaloid in the leaves, different from caffeine. He found that catha, both in cold blooded and warm blooded animals, produces drowsiness, followed by excessive reflex activity, and, if the dose has been large enough, violent tetanus. Catha evidently belongs among the domestic stimulants, such as tea and coffee, and probably contains an active alkaloid belonging to the caffeine group.

Caulophyllum. U. S. 1890. *Pappoose Root*, *Squaw Root*, *Blue Cohosh*. *Caulophyllum thalictroides* (L.), Michaux (*Leontice thalictroides*, L.), nat. ord. Berberidaceæ.—This is an indigenous, perennial, herbaceous plant, with matted, knotty rhizomes, from which rises a single smooth stem, about two feet high. It was officially described (U. S. P. 1890) as follows: "Rhizome of horizontal growth, about 10 Cm. long, and about 6 to 10 Mm. thick, bent; on the upper side with broad, concave

stem-scars and short, knotty branches; externally grayish-brown, internally whitish, tough and woody. Roots numerous, matted, about 10 Cm. long, and 1 Mm. thick, rather tough; nearly inodorous; taste sweetish, slightly bitter and somewhat acrid." U. S. 1890.

Mayer found caulophyllum to contain saponin and a colorless alkaloid (A. J. P., 1863, 99), while A. E. Ebert subsequently obtained from it albumen, gum, starch, phosphoric acid, extractive, two resins, coloring matter, and a body analogous to saponin. The *caulophyllin* of the eclectics is made by pouring a concentrated alcoholic tincture into water and collecting the precipitate, washing with ether, and drying. J. U. Lloyd purified the substance which Ebert described as analogous to saponin, and for distinction terms it *leontin*. (See *Drugs and Medicines of North America*, vol. ii. 152.) He also obtained *caulophylline*, the alkaloid first announced by Mayer in 1863. Lloyd describes it as colorless, odorless, possessed of little taste, and dissolving freely in water, alcohol, ether, and chloroform. It crystallizes with difficulty. The hydrochloride has been obtained, however, in crystals. It has not been tested physiologically. (Proc. A. Ph. A., 1893, 115.)

Caulophyllum has been used by so-called eclectic and homeopathic practitioners. It is said to be sedative, antispasmodic, and oxytocic, and to have the power when uterine inertia occurs during labor to cause the contractions to become very severe, without altering their general character as does ergot. It is also alleged to be capable of arresting threatened abortion, to be very efficacious in hysteria, amenorrhœa, dysmenorrhœa, menorrhagia, uterine subinvolution, etc.; also to be capable of originating uterine contractions and of producing abortion. For a detailed description of the various contradictory powers ascribed to it, the reader is referred to Lloyd's *Drugs and Medicines of North America*, vol. ii. p. 155. It is given in decoction, infusion, or tincture, the first two being made in the proportion of an ounce to a pint of water, the last of four ounces to a pint of spirit. Dose, of decoction or infusion, one or two fluidounces (30 or 60 Cc.); of tincture, one or two fluidrachms (3.75 or 7.5 Cc.). *Leontin* has been used in doses of one fluidrachm (3.75 Cc.) of the one per cent. solution.

Cayaponia. *Cayaponia globosa*. Silva Manso. This is a cucurbitaceous plant of Brazil, from which Gubler has extracted the alkaloid *cayaponine*, said to purge without griping. Dose, one grain (0.065 Gm.). (Rép. de Pharm., 1879, 193.)

Ceanothus. *Ceanothus americanus*, L. *New Jersey Tea*. Red-root. *Céanothe*, Fr. *Seckelblumen-wurzel*, G.—A small indigenous shrub, of the fam. Rhamnaceæ, growing throughout the Eastern United States. The root is astringent, and imparts a red color to water. H. K. Bowman found in it 9.21 per cent. of tannin. (A. J. P., 1869, 195.) F. C. Gerlach has again examined the root. (A. J. P., 1891, 332.) He finds 6.48 per cent. of tannin and 0.52 per cent. of an alkaloid to which he gives the name *ceanothine*. J. H. M. Clinch has found in the leaves a resin and a volatile oil. (A. J. P., xiv. 1884.) J. A. Buckner (A. J. P., 1891, 428) found 9.45 per cent. of tannin in the leaves. *Ceanothus* is said to be useful in syphilis. Schoepf states that it is purgative. The leaves were used during the Revolutionary War as a substitute for tea. The Mexican *C. cœruleus*, Lagasca (*C. azureus*, Desf.), is used as a febrifuge.

Cearin.—An ointment vehicle capable of taking up a large proportion of water. Issleib makes it from a mixture of one part of carnauba wax and three parts of paraffin or ceresin (bleached by exposure to sunlight only); this is fused and mixed with four times its weight of liquid petrolatum and stirred until cold.

Cedron.—The seeds of the *Simaba Cedron* (R. Br.), Planch., a tree growing in Colombia and Central America, belonging to the Simarubaceæ. The fruit is a large solitary drupe, containing a single seed. A specimen of the dried fruit, sent to George B. Wood from Cartago, in Costa Rica, by Guier, formerly of Philadelphia, was light, of a yellowish-ash color, flattish-ovate, with one edge convex and the other nearly straight, the convex outline terminating at each end in an obtuse point, of which that at the apex was most prominent. It was about two inches long and sixteen lines in its greatest breadth. Within, the seed was loose and movable. Cedron seed is about an inch and a half long, ten lines broad, and half an inch thick, convex on one side, flat or slightly concave on the other, and presenting an oval scar near one extremity of the flat surface. It is often yellowish, hard and compact, but readily cut with a knife, is inodorous, but of a pure and intensely bitter taste, not unlike that of quassia. It yields its virtues to water and alcohol. Lowry obtained from it a crystalline substance, intensely bitter, freely soluble in boiling water, and neutral to test paper, which he supposes to be the active principle, and named *cedrin*. He first exhausted the cedron with ether, then treated it with alcohol, and crystallized from the tincture. (J. P. C., xix. 335.) Cedrin is now an article of commerce in the form of yellowish transparent crystals, easily soluble in water, less so in alcohol.

This medicine has long had great reputation in Central America as a remedy for the bite of serpents. S. S. Purple recommends it as a valuable antiperiodic, with a tendency to purge in large doses. Dose, ten to thirty grains (0.65 to 2.0 Gm.) every four hours. (N. Y. M. J., N. S., xiii.)

Celastrus.—Various species of the Celastraceæ have medicinal properties. In the East Indies the oil obtained from the seeds of *Celastrus paniculata*, Willd., is used as a powerful stimulant and diaphoretic in rheumatism, gout, and various fevers. The oil is said to be deep reddish-yellow, and to become thick and honey-like on keeping. It is sometimes known as *oleum nigrum*. In Abyssinia, according to Dragendorff, the leaves of *C. serratus*, Hochst. (*C. obscurus*, A. Rich.), are used as an antiperiodic under the name of *Add-add*. Dragendorff found in them tannic acid, a volatile oil, and a bitter principle, *celastrine*. (A. J. P., xxvi.) In North America the bark of *Celastrus scandens*, L. (*climbing staff tree*, *false bittersweet*, *fever twig*), has been used in chronic affections of the liver and in secondary syphilis, and is said to be emetic, diaphoretic, and alterative. C. H. Bernhard found in the bark acid and neutral resin, starch, glucose, gum, a caoutchouc-like body, coloring matter, and volatile oil. It yields its virtues best to alcohol of 80 per cent. (A. J. P., 1882, 1.) Wayne stated that he had isolated from *C. scandens* white minute crystals, to which he gave the name of *celastrine*. According to Ugolino Mosso (*Rivista Clinica*, 1891) *celastrine* arrests the frog's heart in systole; does not affect markedly the blood pressure in mammals, and influences the respiration only through its action on the vagus.

The stimulant action is especially manifest on the brain and is not followed by a secondary depression. There is marked, persistent elevation of the temperature.

Celluloid. *Zylonite*.—This material, which has been manufactured into so many useful forms, furnishes an excellent substitute for ivory, tortoise shell, amber, and vulcanite. It is a nitro-cellulose, which is made capable of moulding into any desired form by the admixture of a small amount of camphor. At the temperature at which the camphor melts, it acts as a solvent for the nitro-cellulose and forms a uniform plastic mass with it. This mass may be used directly in the manufacture of various articles, or it may be admixed with mineral coloring matters so as to imitate the various natural stones. The stratified appearance of ivory and the mottled appearance of tortoise shell and amber are obtained by passing between heated rolls plain and colored or clouded celluloid in alternating layers. The material is combustible when ignited, and in thin pieces burns rapidly with a bright light.

Within recent years celluloid varnishes have come into extensive use for lacquering on metal; these are nothing but pyroxylin solutions in which methyl alcohol, petroleum naphtha, and amyl acetate are used as a mixed solvent.

Celtis. *Celtis cinnamomea*, Lindl. *C. reticulosa*, Miq.—W. R. Dunstan has isolated *skatol*, the substance to which the odor of the human faeces is due, from the wood of this East Indian tree. (*P. J.*, June, 1889.)

Centaurea. *Centaurea benedicta*, L. *Blessed Thistle*. *Carduus benedictus*, L. *Cnicus benedictus*, L. *Chardon bénit*, Fr. *Herba Cardui Benedicti*, P. G. *Benedicten Distel*, G.—This is an annual herbaceous composite common in Europe and occasionally seen in the United States. The leaves were formerly official. They should be gathered when the plant is in flower, quickly dried, and kept in a dry place. The herb has a feeble, unpleasant odor and an intensely bitter taste, more disagreeable in the fresh than in the dried plant.

Water and alcohol extract its virtues. The infusion with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The active constituents are volatile oil and *cnicin*. This is crystallizable, inodorous, very bitter, neutral, scarcely soluble in cold water, more soluble in boiling water, and soluble in all proportions in alcohol. Its formula is $C_{42}H_{56}O_{15}$, and it is analogous to salicin in composition. In the dose of five grains (0.32 Gm.) it is said to cause vomiting, while eight grains (0.5 Gm.) given in divided doses, is useful in *intermittent fevers*. (*Ann. Ther.*, 1843, 206.) In cold infusion this drug is tonic; when taken in hot infusion in large quantities it is diaphoretic, or in larger quantities, emetic. Tonic dose, of the infusion (ounce to a pint), two fluidounces (60 Cc.); of the powder, from half a drachm to one drachm (2.0–3.9 Gm.).

Silybum Marianum, Gaertn. (*Mariana Mariana* (L.), Hill, *Carduus Marianus*, L.), was of old used for the same purpose as *C. benedictus*. Rademacher attributed great value to the seeds in *hemorrhages*, particularly when connected with diseased liver or spleen. Lobach found the decoction (two ounces to the pint of water), in doses of four fluidrachms (15 Cc.) every hour, useful in *amenorrhœa* and *menorrhagia*. (*Am. J. M. S.*, April, 1859.)

Centaurium. *Common European Centaurium*. *Centaurium*, *Herba Centaurii*, P. G. *Erythrœa Centaurium* (L.), Pers. (*Gentiana Centaurium*, L., *Chironia Centaurium*, Schmidt) (Willd. *Sp. Pl.* i. 1068).—This is a small, annual herbaceous plant which grows wild in most parts of Europe. The fresh, bitter, odorless herb yields an odorous, pungent distillate (Geiger, ii. 482), in which Méhu has found valeric acid, also a peculiar colorless, crystallizable, non-nitrogenous substance, *erythrocentaurin*, $C_{27}H_{24}O_8$, which he obtained by exhausting the tops with water, evaporating a portion of the water, allowing the residue to stand, separating the precipitated matter or apotheme, adding alcohol to the remaining liquid, which now deposited a bitter substance, and, after the separation of this by decantation, evaporating the liquid to the consistence of syrup, and treating the residue with ether. The ethereal solution, upon evaporation, yielded the erythrocentaurin in crystals. These are needle-shaped, fusing at 136° C. (276.8° F.), and crystallizing easily on cooling again. They are strongly reddened by exposure to solar light, and reacquire their colorless character upon being again dissolved and crystallized, or by mere heating to 130° C. (266° F.). They are almost insoluble in cold water, more readily soluble in boiling water, alcohol, ether, and chloroform. Carbon disulphide, benzene, volatile and fatty oils dissolve them easily. J. F. Huneker believes that erythrocentaurin exists also in American centaurium. (See *Sabbatia*.) Besides these principles, Méhu found also in centaurium a wax-like substance and saline matter. (*J. P. C.*, xliii. 38.) Leuderich assigns to erythrocentaurin the formula $C_9H_{14}O_5$ and states that in its decomposition a dextro-rotatory carbohydrate is produced. (*A. J. P.*, 1892, 311.) The common centaurium of Europe has tonic properties very closely resembling those of gentian.

A species of *Erythrœa*, *E. chilensis*, Pers., is employed to a considerable extent in Chili as a mild tonic. (For details, see *J. P. C.*, 3e sér., xxv. 434.) *E. acaulis*, which grows in great abundance in the territory of French Algiers bordering on the Sahara, yields a root which, under the name of *rejagnou*, is much employed by the natives for dyeing yellow. (*Ibid.*, 4e sér., v. 87.)

Cephalanthus. *Cephalanthus occidentalis*, L. *Button Bush*. *Button Wood*. *Crane Willow*. *Swamp Dogwood*. (Fam. Rubiaceæ).—A common indigenous shrub which grows in moist places, as along streams or on the borders of swamps. Its bark is bitter, is said to be laxative as well as tonic, and has been given in periodical fevers, in decoction or infusion. E. M. Hattan found in it a crystallizable fluorescent acid, a bitter uncrystallizable principle, a principle resembling saponin, tannin, two resins, fatty matter, gum, glucose, and starch. (*A. J. P.*, xlv. 314.) According to Claassen (*Ph. Rund.*, Bd. vii. 1889), the fluorescent acid of Hattan is composed of two substances, *cephalin* and *cephaletin*. Carl Mohrberg has separated from the bark a substance which he knows as *cephalanthin*, and also a toxic saponin-like principle which, like its allied poisons, has the power of dissolving the blood corpuscles. Cephalanthin he finds to be a distinct poison to both cold and warm blooded animals, causing destruction of blood corpuscles with conversion of oxyhæmoglobin into methæmoglobin, violent vomiting, convulsions, and paralysis. (See *Kobert's Arbeiten*, viii. 1892.)

Ceratopetalum.—The New South Wales species of this genus yields considerable quantities of a kino-like gum. (See *P. J.*, xxi. 742.)

Cercis. *Cercis canadensis*, L. *Judas Tree*. *Red-bud.*—The bark of this beautiful leguminous tree, indigenous and well known throughout the Eastern and Central United States on account of its brilliant red-purple flowers, which appear before the leaves, has been highly recommended by Wm. R. Smith as a mild but very active astringent in the treatment of chronic diarrhœa and dysentery. *Dose*, of the fluidextract, from half to one fluidrachm (1.8 to 3.75 Cc.).

Ceresin.—Under this name there has been introduced into commerce, as a substitute for wax, a substance which closely resembles white wax, but which is a natural mineral product. It is found most abundantly in Galicia, on the slopes of the Carpathian Mountains, and also on the Wallachian side of the range, under the name of *ozokerite* (*earth-wax*), but occurs in smaller deposits along the Caspian under the name *neft-gil*. A valuable deposit has also been discovered in Southern Utah. It consists of a mixture of solid paraffin with some oxygenated bodies. The crude ozokerite is melted to allow earthy impurities to settle out, is treated with sulphuric acid and alkali, as in the treatment of paraffin, and is clarified by bone black, or, better, the black from the manufacture of yellow prussiate of potash. The refined ozokerite or ceresin melts between 61° and 78° C. (142° and 172° F.), is quite odorless and colorless, and has the appearance of beeswax. It may be distinguished from the latter by its lower specific gravity (0.753 at 98° C. (208.4° F.) against 0.822) and its absolute resistance to alcoholic potassium hydroxide, no trace of saponifiable matter being present. The production of Galician ozokerite in 1886 amounted to 13,925 tons, but had fallen in 1896 to 7925 tons. The production of Utah ozokerite in 1890 amounted to 350,000 pounds. The Galician product is worked chiefly in Vienna and in London, where ozokerite candles are manufactured. (See *A. J. P.*, xlv. 11.) In this country ceresin bottles have largely replaced the gutta-percha bottles formerly used to contain hydrofluoric acid.

Cerium Bromide. Ce_2Br_6 .—This salt was prepared by Charles Bullock by calcining cerium oxalate in a porcelain capsule until it became converted into the yellowish-brown sesquioxide, dissolving this in hydrochloric acid, precipitating with sodium carbonate, and dissolving in hydrobromic acid, then evaporating at a low temperature to dryness. The salt is of a light chocolate color, and of a very styptic sweetish taste, soluble in 95 per cent. alcohol, partially soluble in water. (*A. J. P.*, xliii. 345.)

Cetraria. *U. S.* 1890. *Iceland Moss.* *Iceland Lichen.*—Under this name the *U. S. P.* formerly recognized the dried plant of *Cetraria islandica*, Acharius, *Lichen islandicus*, L. This plant, although known as a moss, is not a moss, but a lichen which grows in most northern latitudes and on elevated mountains further south, including the Northern United States.

The dried moss is of diversified color, grayish white, brown, and red, in different parts, with less of the green tint than in the recent state. It was officially characterized as follows. "From 5 to 10 Cm. long, foliaceous, irregularly branched into fringed and channelled lobes, brownish above, whitish beneath, and marked with small, depressed spots; brittle and inodorous; when soft-

ened in water, cartilaginous, and having a slight odor; its taste is mucilaginous and bitter." *U. S.* 1890. Macerated in water, it absorbs rather more than its own weight of the fluid, and, if the water be warm, renders it bitter. Boiling water extracts all its soluble principles. The decoction thickens upon cooling, and acquires a gelatinous consistence without viscosity. After some time the dissolved matter separates, and when dried forms semi-transparent masses, insoluble in cold water, alcohol, or ether, but soluble in boiling water, and in solution forming a blue compound with iodine. *Lichenin*, or *lichen starch*, $\text{C}_{12}\text{H}_{20}\text{O}_{10}$, resembles starch in its general characters, but differs from it in some respects. Lichenin has been found to consist of two distinct proximate principles, for one of which the name lichenin may be retained, while for the other no particular designation has been chosen, but which we may call *lichenoid*. According to Th. Berg (*Thèse de Dorpat*, 1872), cetraria yields 35.15 per cent. of the mixed principles, of which 20 per cent. is of lichenin, and 15.15 of the so-called lichenoid. To separate them, a decoction of the moss, concentrated to a small bulk, and still hot, is treated by alcohol. The lichenoid is deposited in flocculi, which gradually unite in a viscid mass. This, being washed by alcohol until it ceases to be bitter, and then dried, yields a light friable matter partly soluble in cold water, with which it forms a yellow, limpid solution. To deprive it of mineral and coloring substances, it is dissolved in a little water, and precipitated afresh by alcohol. Lichenin is insoluble in cold water, but swells up and easily dissolves in hot water. It is insoluble in alcohol and in ether. It is only tinged by iodine. Lichenoid is, on the contrary, colored blue by that reagent. It is, in part, dissolved in cold water, and the undissolved part is equally colored blue by iodine. It is, like lichenin, insoluble in alcohol and ether. Both substances have strong analogies with starch, yet are distinct. For a further account, see *J. P. C.*, 1873.

The name *cetrarin* has been conferred on the bitter principle. Herberger's process for extracting it may be found in the 18th ed., *U. S. D.* By it one pound of moss yielded to Herberger 133 grains of cetrarin. This principle is white, not crystalline, light, unalterable in the air, inodorous, and exceedingly bitter, especially in alcoholic solution. Its best solvent is absolute alcohol, of which 100 parts dissolve 1.7 of cetrarin at the boiling temperature. Ether also dissolves it, and it is slightly soluble in water. Its solutions are quite neutral to test paper. It is precipitated by the acids, and rendered much more soluble by the alkalis. Concentrated hydrochloric acid changes its color to a bright blue. It precipitates the salts of iron, copper, lead, and silver. In the dose of two grains (0.13 Gm.) every two hours, it has been used successfully in intermittent fever. (*J. P. C.*, xxiii. 505.) Schnedermann and Knop have ascertained that the cetrarin above referred to consists of three distinct substances: 1, *cetraric acid*, $\text{C}_{12}\text{H}_{16}\text{O}_8$, which is the true bitter principle, crystallizable, and intensely bitter; 2, a substance resembling the fatty acids, called *lichen-stearic acid*, $\text{C}_{14}\text{H}_{24}\text{O}_8$, the crystals of which melt at 120° C. (248° F.); and, 3, a green coloring substance, which they name *thallochlor*. These principles are obtained perfectly pure with great difficulty. (*Ann. Ch. Ph.*, lv. 144.) Hilger and Buchner (*Ber. d. Chem. Ges.*, 1890, p. 461) have extracted both lichen-stearic

and cetraric acids and studied them more fully. They give to the former the formula $C_{43}H_{76}O_{13}$, and to the latter the composition $C_{30}H_{50}O_{12}$, and both are shown to be dibasic acids.

The gum and starch contained in the moss render it sufficiently nutritive to serve as food for the Lapps and Icelanders, who employ it powdered and made into bread, or boiled with milk, after having partially freed it from the bitter principle by repeated maceration in water. As suggested by Berzelius, the bitterness may be entirely extracted by macerating the powdered moss, for 24 hours, in twenty-four times its weight of a solution formed with 1 part of an alkaline carbonate and 375 parts of water, then decanting the liquid, and repeating the process with an equal quantity of the solution. The powder, being now dried, is perfectly sweet, and has been used to some extent in pharmacy as a substitute for acacia, although lacking in adhesiveness. (See also *Gelatina Lichenis Islandici Saccharata Sicca* (Germ. Unoff. Formulary), *Proc. A. Ph. A.*, 1892, 455.)

Iceland Moss has been much used in chronic catarrhs, especially of the pulmonary mucous membrane and even in phthisis. It acts chiefly as a mucilaginous drink, but as Kobert has found that cetrarin is a stimulant to the gastro-intestinal mucous membrane and to peristalsis, cetraria probably is feebly tonic. A 20 per cent. tincture has been recommended by Deying and Brice-Moret as an anti-emetic (*P. J.*, Oct. 30, 1897).

Decoctum Cetrariæ. *U. S.* 1890. *Decoction of Cetraria*. *Decoction of Iceland Moss*.

"Cetraria, fifty grammes [or 1 ounce av., 334 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Cover the Cetraria, in a suitable vessel, with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of cold Water, express after half an hour, and throw the liquid away. Then boil the Cetraria with one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Water for half an hour, strain, and add enough cold Water, through the strainer, to make the product, when cold, measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.* 1890.

As the bitter principle is dissolved along with the starch-like matter of the moss, this decoction has an unpleasant flavor; but the plan which has been proposed of first extracting the bitterness by maceration in water or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, is inadmissible, as the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. A pint (473 Cc.) of the decoction may be taken during the day. Other species of *Cetraria* appear to be more active than *C. islandica*.

The *Cetraria juniperina* (probably *Cetraria vulpina*) of Europe is said to be sometimes used as a poison for wolves and foxes, while the wolf's moss (*Ulfmossa*) of the north of Europe contains vulpinic acid, $C_{15}H_{14}O_5$, which has been found by Kobert to be an active protoplasmic poison; in frogs it produces tetanus, convulsions, and paralysis of central origin; in mammals it causes dyspnea, vomiting, trembling, and a slowing of the pulse, with rise of the blood pressure due to stimulation of the respective nerve centres. After death the blood is not coagulable, and the secreting kidney cells are found covered with a crystalline or amorphous mass of a vulpinate. The acid is found also in species of

Calycium, *Culveraria*, *Parmelia*, and *Cypselium*. (Schmidt, *Ph. Chemie*, St. 1310.) No difference of action exists between vulpinic acid derived from wolf's moss and that synthetically produced. From *Cetraria pinastri* Zopf has separated pinastriinic acid, which seems to be very closely allied to vulpinic acid. (*Sitzungsab. der Dorpat. Naturforsch.-Gesellschaft*, 1892.)

Cetyl Alcohol. Alcohol *Cetyllicum*. $C_{18}H_{38}OH$.—Cetyllic alcohol, ethal, primary hevadecyl alcohol, is a tasteless, odorless, waxy powder, which fuses at $49.5^{\circ} C.$ ($121^{\circ} F.$) and boils at $344^{\circ} C.$ ($651^{\circ} F.$). It is soluble in alcohol and ether. According to Grimm (*Derm. Zeit.*, 1899, vol. vi.), cetyl alcohol is absorbed and obstinately retained by the epidermis, producing a peculiar velvety condition of the skin. It has been found useful in the treatment of chapped hands, weeping eczema, and prurigo. Mixtures of it with boric acid or the borates have been put upon the market as cosmetics under the name of Borsyl. Grimm especially recommends equal parts of cetyl alcohol with boric acid or one part with five of powdered talc.

Chamælorium. *Chamælorium luteum* (L.), A. Gray. *C. carolinianum*, Willd. *Veratrum luteum*, L. *Helonias lutea*, Ker-Gawl in *Bot. Mag. Helonias dioica*, Pursh. *Starwort*. *False Unicorn Root*. *Devil's Bit*. *Blazing Star*.—This plant is indigenous to the United States. The rhizome is the part employed in medicine. It is commonly known by the erroneous name *Helonias*. F. V. Greene obtained from it in 1878 a bitter principle, *chamælorin*. He states that it is a cardiac poison. *Helonin* is a term used by the eclectics to define the alcoholic extract found in commerce. *Chamælorium*, or *starwort*, is said to be diuretic, tonic, and anthelmintic. It is usually given in aqueous infusion, 1 in 16, in the dose of a wineglassful.

Champaca-Camphor. *Champacool*. $C_{17}H_{30}O$. This camphor was first separated by Merck from *champaca-wood*. (See *Merck's Annual*, 1893, also *Schim. Rep.*, 1897, 11.)

Cheiranthus. *Cheiranthus Cheiri*, L.—From the leaves of this cruciferous European plant Moritz Reeb (*A. E. P. P.*, 1899, vol. xliii.) has obtained a glucoside, belonging to the digitalis group, of such power that 0.0005 Gm. will produce systolic cardiac arrest in the frog; also a crystalline alkaloid, *cheirinin*, $C_{15}H_{25}N_3O_{17}$, which acts upon nerve centres and also upon muscles.

Chelidonium. *U. S.* 1890. *Chelidonium majus*, L. (nat. ord. Papaveraceæ.) *Celandine*.—Celandine is a perennial herbaceous plant growing wild in both Europe and America, recognized readily by its pinnate leaves, small peduncled yellow flowers and yellow opaque juice. The plant was formerly official and was described as follows: "Root several-headed, branching, reddish-brown; stem about 50 Cm. long, light green, hairy; leaves about 15 Cm. long, thin, petiolate, the upper ones smaller and sessile, light green, on the lower side glaucous, lyrate-pinnatifid, the pinnae ovate-oblong, obtuse, coarsely crenate or incised and the terminal one often three-lobed; flowers in small, long-peduncled umbels with two sepals and four yellow petals; capsule linear, two-valved and many-seeded. The fresh plant contains a saffron-colored milk-juice, and has an unpleasant odor and acrid taste." *U. S.* 1890.

Probst of Heidelberg, found in it a peculiar acid denominated *chelidonic acid*; two alkaline principles, one of which forms neutral salts with

the acids, and is called *chelerythrine* in consequence of the intense redness of its salts; the other unites with but does not neutralize the acids, and is named *chelidonine*; and lastly a neutral crystallizable, bitter principle, which from its yellow color he calls *chelidoxanthin*. Orlow believes, however, that the latter is an alkaloid, and gives a process for its preparation in *Ph. Z. R.*, 1893, No. 21. *Chelerythrine* appears to be an acrid narcotic poison. (*Ann. Ch. Ph.*, xxix, 113.) For color tests for *chelidonine*, see *Proc. A. Ph. A.*, 1895, 992. *Chelidonine phosphate*, *chelidonine sulphate*, and *chelidonine tannate* have been used medicinally. (See *Proc. A. Ph. A.*, 1897, 721.)

In 1889 Schmidt announced the presence of twelve different bases in *chelidonium*, four of which he has studied: *chelidonine*, $C_{20}H_{19}NO_5 + H_2O$; *methylchelidonine*; *alpha-methylchelidonine* and *beta-methylchelidonine*, represented by the formula $C_{21}H_{21}NO_5$. These bases were ascertained to possess physiologically an action resembling that of morphine. (*Ph. Ztg.*, 1889, p. 582.) Schmidt (*A. J. P.*, 1890, p. 13) also found *protopine*, and showed the identity of *stylophorine*, from *Stylophorum diphyllum* (Michx.), Nutt. (*Chelidonium diphyllum*, Nutt.), with *chelidonine*. This last result was confirmed by Selle. (*A. J. P.*, 1890, p. 176.) Selle later (*A. Pharm.*, 1890, 441-462) sums up the composition of *Chelidonium majus* as follows: it contains, besides *chelidonine* and *chelerythrine*, three other alkaloids, called *alpha-homochelidonine*, $C_{21}H_{21}NO_5$, *beta-homochelidonine*, $C_{21}H_{21}NO_5$, and *protopine*, $C_{20}H_{17}O_5$. These results practically agree with those before obtained by Schmidt. The identity of *chelerythrine* and *sanguinarine* is not conceded by G. König. (*Chem. Cb.*, 1891, p. 321.) He gives the composition $C_{21}H_{17}NO_4$ to the former and $C_{20}H_{15}NO_4$ to the latter, making one the methyl derivative of the other and with this conclusion Schmidt also agrees. In 1902 J. O. Schlotterbeck showed that the *chelidoxanthine* of Probst is really *berberine*. Schlotterbeck has also established the identity of the most abundant of the alkaloids of *sanguinaria* with *chelerythrine*.

Celandine is an irritant purgative to which toxic properties have been ascribed with doubtful correctness; in the fatal case of poisoning reported in the *Zeitsch. f. Medizinalbeamte*, 1898, it was not the cause of death. The irritant juice has long been used locally upon *corns*, *warts*, *eczema*, and other diseases of the skin, and even in *cancer*. The dose of the dried root or herb is from thirty grains to a drachm (2.0-3.9 Gm.), that of the fresh root one or two drachms (3.9-7.7 Gm.), and the same quantity may be given in infusion. The dose of the aqueous extract is from five to ten grains (0.32-0.65 Gm.), of the expressed juice from ten to twenty minims (0.6-1.3 Cc.), to be gradually increased. The allegation of Peronin that *chelidonine sulphate*, in doses of from one-twentieth to one-third grain (0.003-0.021 Gm.), is an active analgesic and somnifacient has not been confirmed by subsequent observers.

Chelone. *Chelone glabra*, L. *Snake-head*. *Turtle-head*. *Balmory*. *Shellflower*. *Chelone*, Fr., G.—The leaves of this very common indigenous, perennial, herbaceous plant, of the fam. *Scrophulariaceae*, have a bitter taste, and are said to be tonic and aperient, with a supposed peculiar action on the liver. The decoction (two ounces of the fresh herb to the pint) may be given in the dose of one or two fluidounces (30-60 Cc.).

Cheltenham Salt, Artificial.—Several artificial mixtures have been prepared as imitations of the salts of the chalybeate Cheltenham water. One frequently used is equal parts of magnesium sulphate, sodium sulphate, and common salt; other formulas contain some iron. These combinations are used as laxatives in *glandular obstructions*, especially of the *liver*, and in *scrofulous affections*, attended with feeble digestion, sluggish bowels, and pallidness of skin; also in *habitual costiveness* and *hemorrhoids*.

Chenopodium. *Chenopodium*. *American Wormseed*.—The fruit of *C. Neuopodium* (*anthelminticum*), Linné (nat. ord. *Chenopodiaceae*).

This species of *Chenopodium*, known commonly by the names of *wormseed* and *Jerusalem oak*, grows in almost all parts of the Eastern United States. The whole herb has a strong, peculiar, offensive, yet somewhat aromatic odor, which it retains when dry. All parts of the plant are occasionally employed, but the fruit alone was official in the U. S. P. 1890. This should be collected in October.

Wormseed, as found in commerce, is in small grains, not larger than the head of a pin, irregularly spherical, very light, of a dull greenish-yellow or brownish color, a bitterish, somewhat aromatic, pungent taste, and possessed in a high degree of the peculiar odor of the plant. These grains, when deprived, by rubbing them in the hand, of a capsular covering which invests the proper seed, exhibit the shining, blackish surface of the obtusely-edged seed. They abound in a volatile oil, upon which their sensible properties and medicinal virtues depend and which is obtained by distillation. (See *Oleum Chenopodii*, p. 841.) The same oil impregnates to a greater or less extent the whole plant.

Of the activity of the wormseed as an anthelmintic there can be no question. Given in doses of from 20 to 40 grains (1.3-2.6 Gm.) with calomel and followed by a purgative it is very effective. In practical medicine it has been entirely replaced by the official volatile oil.

China Morada.—Under this name there appear to be used in Bolivia several barks. One of these has been ascertained by Arati and Canzoneri (*L'Orosi*, Feb. 1889) to be the product of a rubiaceous tree, *Pogonopus* (*Chrysocylum*) *febrifugus*, and to contain an alkaloid, *moradeine*, besides a fluorescent substance, *moradin*, allied to *scolopetin*. (See *P. J.*, xix.)

Chinaphenine. $CO \begin{cases} NH.C_6H_4OC_2H_5 \\ OC_{20}H_{23}N_2O \end{cases}$ *Quinine Carbophenetidide*.—Chinaphenine occurs as a white, tasteless powder, slightly soluble in water, easily in alcohol, ether, and chloroform and benzene, forming salts which are soluble in water. Chinaphenine has been recommended by von Noorden as a mild antipyretic, producing a fall of temperature which is at its lowest point four or five hours after the ingestion of the remedy; also as an analgesic in *diabetic* and other forms of *neuralgias*; also in *whooping cough*. The analgesic dose is twenty to thirty grains (1.3-2.0 Gm.) given in two portions. To children under a year old, von Noorden gave two to three grains (0.13-0.20 Gm.) and older children three to five grains (0.21-0.32 Gm.) three times a day. (*Ther. Geg.*, Jan. 1903.)

Chinaphthol. *Quinaphthol*. *Quinine-β-naphthol-a-mono-sulphonate*. $C_{20}H_{21}N_2O_2(C_{10}H_7OHSO_3H)_2$.—This substance is a yellow crystalline powder fusing at 185° C. (365° F.), of a bitter

taste, insoluble in cold water, moderately soluble in hot water and alcohol; it has been proposed by E. Riegler (*W. M. Bl.*, xix, 1896) as an antipyretic and intestinal antiseptic. He states that it is decomposed by the alkalies of the intestinal juices into its constituents,—namely, quinine and β -naphthol sulphuric acid, and that he has used it up to 75 grains (5 Gm.) a day with satisfaction in acute rheumatism as well as in typhoid fever. It contains about 42 per cent. of quinine.

Chinoidinum. *U. S.* 1880. *Chinoidine. Quinoidine. Chinoidin. Quinoidin. Precipitated Extract of bark. Amorphous Quinine. Quinine brute ou amorphe, Fr.*—The term chinoidine was first applied to all of the amorphous alkaloids existing naturally in cinchona bark, but it is now used to define a complex body consisting not only of the natural amorphous alkaloids, but those which are artificial and accidental in the derivative products resulting from the application of heat. Upon the evaporation of the mother liquor left after the crystallization of the quinine sulphate in the preparation of that salt, a dark colored substance is obtained, having the appearance of an extract. Sertürner supposed that he had discovered a new alkaline principle in this product, but his conclusions were invalidated by the experiments of Henry and Delondre, which went to prove that the alkaline matter contained in it consisted of quinine and cinchonine, obscured by admixture with a yellowish substance that interfered with their crystallization. Nevertheless, under the name of *quinoidine* or *chinoidine*, given to the supposed new alkaloid by Sertürner, there has been long employed in Europe a substance precipitated from the mother liquor of quinine sulphate by means of an alkaline carbonate, having a yellowish-white or brownish color, and when moderately heated, agglutinating into a mass of resinous appearance. By the conjoint labors of the chemists, Winckler, Liebig, and Pasteur, it was proved that ordinary quinoidine, or amorphous quinine, consisted of two alkaloids, derivatives from quinine and cinchonine, with which they are respectively isomeric, though differing in being uncrystallizable, and named, in view of their origin, *quinicine* and *cinchonidine*. The pure amorphous quinine of Liebig is the former of these alkaloids. The *amorphous quinine*, as Liebig calls it, is entirely soluble in diluted sulphuric acid and in alcohol, and, if its solution in a diluted acid yields upon the addition of ammonia exactly as much precipitate as there was of the original substance dissolved, it may be considered pure. (*A. J. P.*, xviii, 181.) The *U. S. P.* of 1880 described chinoidine as “a brownish-black or almost black solid, breaking, when cold, with a resinous, shining fracture, becoming plastic when warmed; odorless, having a bitter taste and an alkaline reaction. Almost insoluble in water, freely soluble in alcohol, chloroform, and diluted acids; partially soluble in ether and in benzol. The solutions have a very bitter taste. If Chinoidin be triturated with boiling water, the liquid, after filtration, should be clear and colorless, and should remain so on the addition of an alkali (abs. of alkaloidal salts). On ignition, Chinoidin should not leave more than 0.7 per cent. of ash.” *U. S.* 1880.

A simple method of purification consists in dissolving the chinoidine in diluted hydrochloric acid, adding water, filtering and precipitating with an alkali and washing and drying the precipitate.

Tinctura Chinoidini was formerly made, by the German Pharmacopoeia, by simply dissolving 3 parts of chinoidine in one of hydrochloric acid and 17 of alcohol, sp. gr. 0.894.

Chinoidine hydrochloride is made by heating 1 part of the purified chinoidine with 4 parts of distilled water, adding sufficient diluted hydrochloric acid to complete the solution, filtering, evaporating, and powdering the residue. Zimmer furnishes the German market with the purified hydrochloride, under the name of *Chininum amorphum muriaticum purum*. It has been largely used medicinally. For formulas for various salts of chinoidine, see *N. R.*, 1882, 11, or *Proc. A. Ph. A.*, 1882, 417.

As an antiperiodic, chinoidine is inferior to the cinchona alkaloids and more nauseating. From thirty grains to a drachm (2.0–3.9 Gm.) may be given in the interparoxysmal periods of an *intermittent*, and its action closely watched.

Chinol. *Quinoline mono-hypochlorite.* $C_9H_6N.ClO$.—A white crystalline powder, odorless, having a pungent but not disagreeable taste. It is almost insoluble in cold and hot water, but quite soluble in alcohol. This substance is said to be actively antipyretic and analgesic, useful for the purposes for which antipyrin is employed. *Dose*, from three to five grains (0.2–0.32 Gm.).

Chinoline. *Quinoline. Leucoleine. Chinoline, Fr. Chinolin, G.* (C_9H_7N).—This is an artificial alkaloid prepared by the destructive distillation of quinine or cinchonine with potassium hydroxide, and also synthetically by König's and Skraup's processes by the action of sulphuric acid and glycerin upon nitrobenzene and aniline, or a mixture of these two latter substances. Chinoline is a colorless, strongly refractive, oily liquid, having a specific gravity of 1.081 at 10° C. (50° F.) (Hoffmann), boiling at 235.6° C. (456.8° F.) without decomposition, the oily stain left on bibulous paper disappearing readily on exposure. Its odor is aromatic, resembling that of oil of bitter almond. It is sparingly soluble in cold water, more so in hot water, soluble in alcohol, and mixes in all proportions with ether, carbon disulphide, methyl alcohol, etc. It easily dissolves camphor and resin. It gradually turns reddish-brown in color on exposure to the air. It forms readily crystallizable salts with acids, the tartrate now being a commercial article; these salts are decomposed by contact with fixed alkalies and the peculiar odor of chinoline developed. Ekin (*P. J.*, Feb. 11, 1882) found a sample of commercial German chinoline to consist largely of a mixture of aniline and nitrobenzene, although labelled pure. *Quinoline tartrate* is in the form of a whitish, micaceous, crystalline powder, melting at 125° C. It dissolves in 80 parts of cold water, in about 150 parts of alcohol, and in 300 parts of ether, having a peculiar pungent odor and a rather sharp though not unpleasant taste. *Quinoline hydrochloride* melts at 94° C. (201.2° F.) and sublimes unchanged. It dissolves in water, alcohol, and chloroform. *Quinoline salicylate* is a white crystalline powder, soluble in water and in glycerin, very soluble in alcohol, ether, vaseline, and fatty oils.

Quinoline was first brought forward as a substitute for quinine by Julius Donath of Hungary. (*Ber. d. Chem. Ges.*, xiv, 1769.) It appears to be a powerful antipyretic and a stronger antiseptic even than phenol and to act as a powerful depressant upon the central nervous system. A one per cent. solution completely destroys the coagula-

bility of the blood. Quinoline was at first used by various Continental physicians with alleged excellent results in *malarial fevers*, but subsequent experience showed that the drug is only feebly, if at all, antiperiodic, and very apt to disagree with the stomach. The tartrate was given in doses of fifteen grains (1 Gm.). It has been highly commended as a preservative for anatomical specimens. The formula adopted in the Erlangen Physiological Institute is: quinoline, 5 grammes; sodium chloride, 6 grammes; glycerin, 100 grammes; water, 900 grammes. The ordinary tar quinoline can be used. The liquid is said to have the advantage of preserving all the tissues in their natural condition, except that it removes from them all coloring matter.

For physiological activities of chinoline derivatives, see *Trans. College of Physicians, Edinburgh (Laboratory)*, 1893.

Chinosol. *Quinisol.* $C_9H_6ON \cdot SO_3K + Aq.$ *Potassium Oxyquinoline Sulphonate.*—This is a neutral compound of oxyquinoline from which the latter is readily liberated in a nascent condition.

It is a crystalline yellow powder, very soluble in water, insoluble in alcohol and ether, having a feeble aromatic odor. Its aqueous solution when very dilute strikes with ferric chloride a lively green color.

Chinosol does not precipitate albumin, is affirmed to be very slightly toxic, unirritating, and possessed of an extraordinary power of penetrating tissues. It has been commended by a large number of German and English clinicians as a very advantageous antiseptic, which even exceeds in power corrosive sublimate; but Giovanni asserts that in regard to the chancre poison it is inferior to phenol. Moor found the bacillus of the plague to be killed by it in ten minutes in a dilution of 1 in 500. It has been very highly recommended by Gilles and others in the treatment of *vaginitis* and other affections of the female genital organs, in the form of douches of 1 in 1000 to 1 in 8000; also as a local application in *leprosy*, in *lung* and *bone tuberculosis*, and, mixed with from 5 to 10 per cent. of boric acid, as a powder to be used as a substitute for iodoform. Schifferdecker states that the irrigation of cadavers through their arteries with a 5 per cent. solution is an effective means of preservation.

As a disinfectant to the hands, skin, and suture threads, according to F. Hobday, chinosol may be used in as strong solution as 1 in 60, without the production of irritation of skin or wound. On the other hand, it rapidly attacks surgical instruments, taking off their edge and causing greenish-black spots upon them. Internally it has been especially used by A. G. Cipriani in the treatment of *tuberculosis*, both by mouth and injected locally. (*Allgemeine Medicin Central-Zeitung*, Bd. lxxvi.) It is probably more toxic than has been generally supposed, since in Hobday's experiments a dose of one-sixteenth of a grain for each pound of body weight was found to be the extreme limit that could be given to cats without serious danger. As a local application the strength most generally useful is probably one-half grain in a fluidounce; although to a very badly infected wound a solution of 1 in 500 may be often applied once, twice, or three times a day with great advantage.

Chinotoxine. *Dichinolindimethylsulphate.*—This synthetic compound is said to possess properties similar to those of curare.

Chionanthus. *Chionanthus virginica*, L. *Fringe Tree.* (Fam. Oleaceæ).—In the bark of this indig-

enous plant saponin was found by R. S. Justice (*A. J. P.*, xlvii, 195), but not by W. von Schulz, who, however, (*Ph. Z. R.*, 1893, 579), detected a glucoside. The fluidextract has been recommended in doses of from one-half to one fluidrachm (1.8–3.75 Cc.) two or three times a day, as an aperient and a diuretic.

Chione. *Chione glabra.* *Violette.*—The bark of this West Indian rubiaceous plant is said to be largely used as an aphrodisiac and tonic. According to B. H. Paul and A. J. Cownley, it yields 1.5 per cent. of a pale yellow volatile oil composed largely of phenol. (*P. J.*, vol. lx.)

Chloral Ammonium: $CCl_3CH(NH_2)OH$. *Trichloramido-ethyllic Alcohol.*—This substance is said by W. B. Nesbit to act like hydrated chloral, but to be a stimulant to the circulation in doses of from five to twenty grains (0.32–1.3 Gm.). For method of preparation, see T. G., 1888.

Chloral Amylene Hydrate. *Amylene-chloral.* *Dormiol.* $CCl_3CHOHOC_6H_{11}$.—Made by mixing 10 parts of anhydrous chloral with 6 parts of amylen hydrate. It is a colorless, oily liquid having a pungent, mint-and camphor-like odor and a cooling pungent taste. It is not miscible with cold water and is decomposed by boiling water, but is freely soluble in alcohol, ether, acetone, and the fixed oils. Used as a hypnotic in doses of one-half to one fluidrachm (1.8–3.75 Cc.) of a 10 per cent. solution.

Chloral Caffeine.—Made by mixing 10 parts of caffeine and 7.8 parts of hydrated chloral, in a small amount of water or alcohol, and evaporating at a low temperature.

The resulting product is soluble in water and alcohol.

Chloral Camphor. *Camphorated Chloral.*—This is a thick, oily liquid, made by rubbing up equal parts of camphor and hydrated chloral. It distills slowly without change, and dissolves in 60 per cent. alcohol, from which it is precipitated by the addition of water. (*A. J. P.*, 1886, 282.) Chloral camphor is used in *neuralgia* as a counter-irritant and local anesthetic. Conflicting opinions have been expressed about the character of this liquid, the fact that both substances could be obtained unchanged by precipitating its alcoholic solution with water being regarded as proof of its being simply a mechanical mixture. Cazeneuve and Joubert believe, however, that chemical combination has been effected, and point to its optical behavior as proof.

Chloral Carbamide.—When 165.5 parts of trichloraldehyde hydrate are mixed in a porcelain mortar with 60 parts of carbamide (urea), the mixture liquefies. On dissolving this substance in three times its quantity of water warmed to 60° C. (140° F.) and then allowing the mixture to cool, a crystalline mass, chloral carbamide, is obtained. This substance dissolves readily in warm water and in alcohol, and less readily in warm alcohol. According to Kobert, it acts like hydrated chloral, but is too slow and uncertain to be of practical value.

Chloral Carbol. *Carbolated Chloral.*—According to Boureiz, when hydrated chloral and phenol are rubbed up in the proportion of 10 parts of the former to 14 parts of the latter, a liquid is obtained which has the sp. gr. of about 1.5, and is soluble in all proportions in water, alcohol, and ether. Applied locally it is a counter-irritant and local anesthetic. See *Chloral Phenol*, page 1445.

Chloral Cyanhydrate.—This is a compound first prepared by Pinner and Bischoff, and recom-

mended by Hermes (*Ph. Centralt.*, Aug. 1887) as a substitute for hydrocyanic acid, whose physiological action it is stated to share. Chloral cyanhydrate is represented by the formula $\text{CCl}_3\text{—CH—}\begin{cases} \text{OH} \\ \text{CN} \end{cases}$, and is described as a crystalline powder, consisting partly of colorless prisms and partly of rhombic tables, fusing at 61°C. (141.8°F.), easily soluble in water, alcohol, and ether. With the vapor of water it volatilizes in small quantity, and breaks up into its components, chloral and hydrocyanic acid. It is also decomposed by alkalis, with the formation of alkaline cyanides. Its aqueous solutions remain unaltered for a long time. Six and a half parts by weight of chloral cyanhydrate correspond with one part of anhydrous hydrocyanic acid.

Chloral Menthol. *Mentholated Chloral.*—This is obtained by triturating equal weights of hydrated chloral and menthol, and heating gently in a water bath until liquefied. It is an oily, colorless liquid, with a distinct mint-like odor and warm taste, having a specific gravity of 1.1984. It is freely soluble in alcohol, chloroform, and petroleum benzin. (*A. J. P.*, 1886, 283.) Chloral menthol has been used as a counter-irritant and local anæsthetic in facial and other neuralgias.

Chloral Phenol. *Phenolated Chloral.* *Chloral Carbol.*—Made by mixing equal weights of hydrated chloral and phenol, by trituration. In the form of a colorless viscid liquid, having the odor of hydrated chloral, a sweet caustic taste and producing a blister when placed on the skin. It mixes with alcohol, acetic acid, chloroform, carbon disulphide and ether. It has been used to relieve toothache by saturating a piece of cotton and inserting it in the cavity in the tooth.

Chloral Urethane. *Uraline.*—*Uralium*, $\text{CCl}_3\text{CH}\begin{cases} \text{OH} \\ \text{NHCO}_2\text{C}_2\text{H}_5 \end{cases}$ is a compound of chloral and urethane. It is insoluble in cold water, and is decomposed by boiling water; it is soluble in alcohol and ether, and melts at 103°C. (217.4°F.). According to G. Poppi (*Rif. M.*, 1889), this substance as a hypnotic is equal to hydrated chloral, and has the superiority of not acting on the heart and of being tolerated better. J. Schmitt, however (*R. M. Est.*, May, 1890), finds that it does act upon the heart, arresting it in diastole, and resembling very closely chloral in its physiological action, and having the inconvenience of great insolubility. J. Schmitt and P. Parisot (*R. M. Est.*, Dec. 1890) found that unless given in doses of fifteen and a half grains (1.032 Gm.) it was very uncertain in its action as a medicine, and was likely to disagree with the stomach, being on the whole inferior to hydrated chloral.

Chloralose. $\text{C}_8\text{H}_{11}\text{Cl}_3\text{O}_6$. *Anhydro-gluco-chloral.* When equal parts of anhydrous chloral and glucose are heated together for an hour at the temperature at which chloral boils, two isomeric substances—*chloralose*, which is soluble, and *parachloralose*, which is insoluble—are formed. Chloralose occurs in small crystals having a very bitter and disagreeable but not acrid taste. It is freely soluble in alcohol and in hot water, slightly so in cold water, a little less than five grammes to the litre. Its melting point is 185°C. (365°F.). Chloralose was first brought forward as a remedial agent by Hanriot and Richet (*C. R. S. B.*, 1893), who state that five grammes of it will produce in a dog of ten kilogrammes' weight symptoms of intoxication, followed by a most profound sleep, in which all sensibility is lost, although the

reflex activities are greater than normal. Upon the circulation the drug has but little power, the arterial pressure, even when there is profound anæsthesia, being scarcely affected. During the anæsthesia not only was the spinal motor side of the cord more active than normal, but the motor cerebral cortex was found to be excessively excitable, the animals experimented upon offering a strong contrast with chloralized dogs, in which the psychomotor cortex was almost devoid of responding power.

As a practical hypnotic, the action of chloralose is very variable and is often attended by disagreeable results, ten grains frequently failing to cause sleep, although the same amount has produced complete unconsciousness with alarming symptoms. Partial general paralysis, tremors, great slowing of the pulse, and marked evidences of enfeebled heart action have not rarely followed the use of the drug, while involuntary discharges of urine, delirious intoxication, excessive vomiting, and other disagreeable symptoms have been noted. The dose is from five to ten grains (0.32–0.65 Gm.), given in capsules.

M. H. Rendu (*Bull. et Mém. de la Soc. Méd. de l'Hôp. de Paris*, xx. 1895), has reported violent collapse, excessively rapid feeble pulse, pronounced disturbance of respiration, epileptiform convulsions, and collapse as produced by four grains (0.26 Gm.) of chloralose.

Chloraloximes.—A series of compounds, whose strong physiological activities are asserted to be due to their splitting up in the system into hydrated chloral and their respective oximes. They are *chloralacetoxime* (melting point, 72°C. , 161.6°F.); *chloralcamphoroxime* (melting point, 98°C. , 208.4°F.); *chloralnitroso β -naphthol* (melting-point, 100°C. , 212°F.); *chloralacetaldoxime* (melting point, 74°C. , 165.2°F.); *chloralbenzaldoxime* (melting point, 62°C. , 143.6°F.). The compounds are easily soluble in alcohol and ether, and are readily recrystallized from petroleum benzin. Water dissolves them with difficulty, and when applied hot is likely to cause decomposition and the re-formation of hydrated chloral. (*Deut. Chem. Zeit.*, 1892.)

Chloretone. *Trichlorbutyl Alcohol.* *Acetone-chloroform.* $\text{CCl}_3\text{.}(\text{CH}_2)_2\text{C.OH} + \frac{1}{2}\text{H}_2\text{O}$.—It forms colorless crystals fusing at 80° to 81°C. (176° – 177.8°F.), difficultly soluble in water, more readily soluble in alcohol and glycerin. Chloretone, in 1894, was introduced to the medical profession as an anæsthetic and hypnotic by J. A. Abel. When given in proper doses it produces in the lower animals a profound sleep with complete anæsthesia without the respiration or blood pressure being seriously affected, although the period of sleep may last some hours or even days. If the dose be sufficient, however, death occurs from asphyxia. Chloretone has no influence upon the blood, very little upon blood pressure, although when brought locally in contact with the heart it acts as a depressant. The bodily temperature is distinctly lowered during anæsthesia. The results of Abel in regard to the toxicity of chloretone have been challenged by E. Impens, who finds that chloretone restricts the combustion of oxygen more than 50 per cent. and that it is more dangerous than hydrated chloral. Certainly, as a hypnotic and general anæsthetic, chloretone has failed to fulfil earlier expectations. This failure may in part be the result of timidity in the use of the drug, the dose having been given as from two to ten grains (0.13–0.65 Gm.), but we have

given thirty grains (2 Gm.) in twelve hours without producing any perceptible symptoms, and a case is reported of one hundred and twenty grains (7.7 Gm.) taken during twenty-four hours, causing sleep for six days, without evil results. As a local anæsthetic chloretone seems to be of distinct value. It has been much used in 1 to 2 per cent. solution as an antiseptic and analgesic application to painful ulcerations; also for vomiting and gastralgia. Ten grains (0.65 Gm.) given before anæsthetization, according to Lewis Hirschmann, reduces the amount of ether required to half, and also lessens the after nausea. The dose of chloretone is five to fifteen grains (0.32 to 1 Gm.). In the physiological laboratory chloretone is a useful anæsthetic, 0.2 Gm. per kilo body-weight being given intravenously when it is desired to keep the animal alive.

Chlorinated Anæsthetic Compounds. **ETHYLENE DICHLORIDE.** *Bichloride of Ethylene. Dutch Liquid. Æthyleni Bichloridum. Æthylenum Chloratum. Etaylum Chloratum. Liquor Hollandicus. Æthylenchlorid, Etaylchlorid, G. C₂H₄Cl₂.* By the mutual action of chlorine and olefant gas an oily liquid is obtained, discovered by four associated Dutch chemists, and called *Dutch liquid*. This Dutch liquid was tried as an anæsthetic by Simpson and by Nunneley. Two forms of the Dutch liquid have been experimented with by Aran of Paris, and one of them furnished very satisfactory clinical results. The liquid which gave the favorable results has been ascertained by Mialhe and Flourens to be the monochlorinated Dutch liquid (*monochlorethylene chloride*, CH₂Cl·CHCl₂), but its cost proved to be too high to allow of its general use at that time as a therapeutic agent. In consequence of this objection to the monochlorinated liquid, Mialhe and Flourens were induced to search for a substitute in the corresponding compound of a parallel series of ethers, formed by the action of successive portions of chlorine on hydrochloric ether, C₂H₅Cl; under these circumstances the hydrogen is replaced by the chlorine, atom for atom, and there are formed the five following compounds: C₂H₄Cl₂; C₂H₃Cl₃; C₂H₂Cl₄; C₂HCl₅; C₂Cl₆. Of this series, the first member is isomeric with the Dutch liquid; the second, third, and fourth with the mono-, bi-, and trichlorinated Dutch liquid, and the fifth is a chloride of carbon, frequently called *carbon sesquichloride*. The first member, though identical with the Dutch liquid in elementary composition and having a vapor of the same density, has, nevertheless, a lower boiling point, i.e. 60° to 64° C. (140°-147.2° F.), while the Dutch liquid boils at 84.9° C. (185° F.); it is also different in chemical properties. Thus, it is not decomposed by an alcoholic solution of potassium hydroxide, as the Dutch liquid is, and is not acted on by potassium, while the Dutch liquid is immediately attacked by it. The explanation of these facts is that the two compounds, while isomeric, or having the same empiric formula, are differently constituted molecularly. Thus, Dutch liquid is known chemically as *ethene dichloride*, CH₂Cl·CH₂Cl, while the chlorinated ethyl chloride is known as *ethylidene chloride*, CH₃CHCl₂. This difference of molecular structure, of course, runs all through their derivatives until the final product C₂Cl₆ is reached in both cases, and here there is identity of product.

The conclusion arrived at by Mialhe and Flourens appears to be that the four chlorinated hydrochloric ethers all possess anæsthetic properties;

and, as it would be difficult to separate them, they propose the use of the mixed ethers, consisting principally of the tri- and quadrichlorinated compounds, as an anæsthetic, under the indefinite name of *chlorinated muriatic ether*. Since the time of Mialhe and Flourens's experiments, the matter has been taken up again, and Taube (A. J. P., 1880, 603, and 1881, 119) proved the availability as anæsthetics of monochlorethylidene chloride, CH₃CCl₂, and of monochlorethylene chloride, CH₂Cl·CHCl₂.

The precise action of the various ethers upon the organism is at present unknown. The committee of the British Association found (B. M. J., i, 1879) the *ethene dichloride* ("formerly named *ethylene dichloride*, or Dutch liquid, C₂H₄Cl₂") to cause convulsions in the lower animals, while E. T. Reichert (P. M. T., xi, 518) found that the "ethylene dichloride" produces anæsthesia with the usual stages, and that, like chloroform, it depresses the heart and steadily lowers the arterial pressure. His experiments seem to show, however, that its action upon the heart is much less powerful than that of chloroform, and in all of his trials the animal died of centric respiratory paralysis while the heart was still maintaining some degree of circulation. He believes, therefore, that it is a much safer agent than chloroform, ranking it between the latter and ether. It is evident that Reichert was not using the same agent as the English committee were, but exactly what he did have is uncertain.

The above bodies are produced sometimes on a considerable scale in the manufacture of chloral. A very variable mixture of the middle members of the series has been sent into commerce under the name of *liquor anæstheticus*. Another similar mixture containing the less chlorinated bodies is the *æther anæstheticus aranii*, boiling between 84° C. (183.2° F.) and 103° C. (217.4° F.). The *æther anæstheticus*, Wiggers, contains the more highly chlorinated products.

ETHYLIDENE CHLORIDE, *chlorinated muriatic ether, ethylene chloride* (CH₃CHCl₂), is a colorless, very mobile, neutral liquid, having an aromatic ethereal odor, and a hot, saccharine taste. It is sparingly soluble in water, but readily soluble in alcohol, ether, and most of the fixed and volatile oils. It is not inflammable, in which respect it agrees with chloroform. When purified it is a liquid somewhat resembling chloroform, of sp. gr. 1.174 at 17° C. (62.6° F.), boiling at 60° C. (140° F.), and not miscible with water. It can be distinguished from chloroform in that it combines with chlorine even in the dark, liberating hydrochloric acid. According to Flourens, its action is similar to that of chloroform. The British Association Committee (B. M. J., 1879, i.) believed it to be a valuable anæsthetic, exerting little or no depressing effect upon the heart, but the work of the committee was not sufficiently thorough to be conclusive. Many years ago Snow used it on man, and gave judgment in its favor, and Binz has produced human anæsthesia, and thinks it increases the force of the circulation (M. T. G., 1879, i.); but Reeve finds (N. R., 1880, 334) that in animals it lowers the arterial pressure, but does not suddenly paralyze the heart, as does chloroform. It is extremely probable that the liquid used by Reichert was this substance, and not the ethylene dichloride, as he thought. (See *Ethylene Dichloride*.)

METHYLENE DICHLORIDE. *Dichloro-methane. Bichloride of Methylene.* CH₂Cl₂.—This was in-

roduced by B. W. Richardson of London. It may be prepared by exposing to sunshine, in a glass globe, pure chlorine and gaseous methyl chloride. The globe has two lateral apertures for the admission of the gases, and below an open neck, which communicates with one of the tubulures of a Woulfe's bottle, of which the other tubulure communicates by a bent tube with a second Woulfe's bottle, and this by another bent tube with a flask. The second bottle is surrounded with ice, and the flask immersed in a freezing mixture, to condense the volatile products. The dichloride condenses in the flask in a pure state, while the contents of the two Woulfe's bottles consist chiefly of chloroform. (Gmelin, vii. 288.)

The methyl chloride may be made for this purpose by heating together 1 part of wood spirit, 2 parts of sodium chloride, and 3 of sulphuric acid, and collecting the evolved gas over water, which retains the impurities. Methyl chloride is a colorless gas, having an ethereal odor and a sweetish taste. (Gmelin.) Richardson found it to possess anæsthetic properties, but to be less manageable than the methylene dichloride. It has been since made more practically by reducing chloroform (trichloromethane) in alcoholic solution by zinc and hydrochloric acid, the product being mixed with water; the specifically heavier liquid separates and is purified by successive treatment with sodium hydroxide solution, sulphuric acid, water, calcium chloride, and finally by fractional distillation.

Methylene dichloride is a colorless liquid, of an odor analogous to that of chloroform, of the sp. gr. 1.344, and the boiling point 40° C. (104° F.). The density of its vapor is 3.012 (Gmelin), 2.937 (Richardson). In its preparation the chlorine replaces one atom of hydrogen in the methyl chloride, thus converting the CH_3Cl (methyl chloride) into CH_2Cl_2 (methylene dichloride). The vapor of the dichloride does not, like that of chloroform, extinguish the flame of a taper, but itself takes fire, burning with a brilliant flame, and yielding, as the result of combustion, carbon dioxide and hydrochloric acid. Methylene dichloride mixes readily with absolute ether, and, as the boiling points of the two approach nearly, they volatilize evenly and equably. It is neutral to test paper and an acid reaction in any specimen would be an evidence of the presence of hydrochloric acid, and should preclude its use as a respiratory anæsthetic. To prevent the generation of the acid, the liquid should be kept carefully secluded from the sunlight, and the addition of a small quantity of absolute alcohol is recommended.

In his experiments upon the lower animals, Richardson found that methylene dichloride was a powerful and advantageous anæsthetic, narcotism being produced more rapidly and continuing longer than when caused by other anæsthetics, passing off, however, with great suddenness. (*M. T. G.*, 1867.) As the result of the paper of Richardson, the dichloride was used as an anæsthetic by various English surgeons, also in Germany and America.

Judging from its chemical constitution, methylene dichloride, containing less chlorine than chloroform, should be the safer of the two agents. It may very well be that the deaths which have occurred from it (*B. M. J.*, Oct. 1869; *Dublin Quarterly Journ.*, Aug. 1870; *P. J.*, 1871, 875) have been due to the commercial drug being something else than it purported to be. Some years ago H. C. Wood had examined in the chemical laboratories of the University of

Pennsylvania methylene dichloride, supplied by one of the most reputable of the English manufacturing chemical firms, and sold as first quality. It contained, however, little or none of the methylene dichloride, and was largely chloroform. Gutzart states, as the result of examination of German specimens of the drug, that they are mixtures of alcohol, methylene dichloride, and chloroform in varying proportions. It seems even probable that Richardson did not have the pure article. The experiments of Geuther and Eichholz, and of Heymanns and Debuck (*Arch. de Pharmacod.*, i.) show that the dichloride acts upon guinea pigs and rabbits similarly to chloroform, but that chloroform is twice as poisonous to the heart. It is possible that methylene dichloride has advantages over chloroform, but the high price of the pure drug must interfere with its use. Any commercial article offered below price may be relied upon as impure. The quantity used by Richardson averaged a fluidrachm (3.75 Cc.) every five minutes. As yet methylene dichloride cannot be regarded as a safe anæsthetic. Even the mixture of methylene dichloride and absolute ether, which Richardson introduced under the name of *methylene ether* (*M. T. G.*, ii. 1872; i. 1873), has caused death. (*P. M. T.*, iii. 718; *M. T. G.*, July, 1873.)

The methylene dichloride may be given internally in the dose of from ten to thirty minims (0.6–1.8 Cc.), which may be dissolved in dilute spirit.

CARBON TETRACHLORIDE. *Tetrachlor-methane. Carbonei Tetrachloridum. Carboneum Chloratum. Chlorocarbon. Tétrachlorure de Carbone, Formène Perchloré, Fr. Chlorkohlenstoff, G. CCl₄.*—This substance, though discovered by Regnault so early as 1839, did not come into general notice until December, 1865, when it was suggested as an anæsthetic by Simpson of Edinburgh. (*M. T. G.*, Dec. 1865.) It had, however, been previously used as an anæsthetic by A. E. Sansom and John Harley, who experimented with it in 1864, and recorded their experience in Sansom's work on Chloroform, published in May, 1865. (*B. and F. Med.-Chir. Rev.*, 1867, 551.) To procure it, dry chlorine is passed first through a bottle containing carbon disulphide, and then through a porcelain tube filled with pieces of porcelain and kept at a bright red heat. The vapors are condensed in a well cooled receiver, forming a yellowish-red liquid, which is a mixture of carbon tetrachloride and sulphur chloride. The sulphur chloride is removed by slowly adding the liquid to an excess of potash lye or milk of lime, the moisture being set aside, and agitated from time to time until the sulphur compound is decomposed, and then distilled. Chloroform is made to yield it by the substitution of an atom of chlorine for one of hydrogen; thus CHCl_3 (chloroform) becomes CCl_4 (carbon tetrachloride).

Carbon tetrachloride is a transparent colorless liquid, of the sp. gr. 1.599 (Regnault), boiling at 77° C. (170.6° F.), with a vapor density of 5.33, and an agreeable aromatic flavor. At 30° C. (86° F.) it solidifies to a crystalline mass. It has already found an extensive use in organic laboratories as a solvent for fats, replacing petroleum benzin to advantage because of its non-inflammability. As a solvent for alkaloids in assay work and in manufacturing processes it takes the place of chloroform. Mixtures of 40 per cent. light petroleum benzin with 60 per cent. carbon tetrachloride, or 50 per cent. benzene with 50 per cent. carbon tetrachloride, are also unflammable.

P. Smith describes its effects as follows. About half a fluidrachm (1.8 Cc.) on a handkerchief was inhaled. The vapors had a quince-like odor, and produced a sense of coolness in the fauces, followed by a feeling of calmness and comfort. A very rapid and fugacious anæsthesia was produced by a larger dose. Small doses of the carbon tetrachloride caused in animals entire loss of power and consciousness, from which they soon recovered entirely; but larger doses occasioned death. These results were confirmed by John Harley. Trials on human beings led to the conclusion that the carbon tetrachloride may be usefully employed, by inhalation, for the relief of pain, especially headache, *tic douloureux*, toothache, *dysmenorrhœa*, etc.

J. Y. Simpson concluded, however, that it depresses the heart much more than does chloroform, and it has failed to come into use. See also *L. L.*, June, 1867. Its vapor, applied to the eye by sprinkling a few drops on the hand, is asserted to be an effectual means of relieving some forms of *conjunctivitis*, *ulceration of the cornea*, *photophobia*, etc. Injected subcutaneously, in the dose of from ten to twenty minims (0.5–1.0 Cc.) it relieved pains in the walls of the chest and abdomen without subsequent nausea. Internally, Simpson tried it only in small doses in *gastrodynia*, in which it had the same effects as chloroform. (*M. T. G.*, 1865, 651.)

Chloroiodolipol.—This is stated to be a chlorine substitution product of phenol, creosote, and guaiacol. It is used in chronic affections of the respiratory tract by inhalation.

Chlorol.—A liquid disinfectant containing mercuric chloride, sodium chloride, hydrochloric acid and copper sulphate, dissolved in water. It should be used with caution.

Chlorolin.—This is a liquid disinfectant said to contain about twenty per cent. of monochlorophenol and trichlorophenol. It is applied to wounds in solutions varying in strength from one-half to three per cent. Pills containing one thirtieth of a grain of chlorolin have been used in the treatment of tuberculosis.

Chlorphenols.—By the action of chlorine upon phenol is produced a mixture of ortho- and parachlorophenol ($C_6H_4Cl.OH.$) and by continued action trichlorophenol ($C_6H_2Cl_3.OH.$). *Orthochlorophenol* is a liquid boiling at $175^\circ C.$ ($347^\circ F.$) and solidifying at $7^\circ C.$ ($44.6^\circ F.$); the *parachlorophenol* forms crystals melting at $37^\circ C.$ ($98.6^\circ F.$) and boiling at $217^\circ C.$ ($422.6^\circ F.$). Both have an unpleasant, penetrating odor. *Trichlorophenol*, which was discovered by Laurent, crystallizes in needles, which melt at $68^\circ C.$ ($154.4^\circ F.$) and boil at $244^\circ C.$ ($471.2^\circ F.$). It is easily soluble in alcohol and ether.

Cech (*Prakt. Ch.*, Bd. xxii.) was the first to show that a mixture of three isomers of monochlor- and trichlorophenols was an extremely active antiseptic, more powerful than phenol itself; but it is chiefly to Karpow, working in the laboratory of Nencki, that we are indebted for our knowledge of these subjects. This investigator found that metachlorophenol is poisonous to the rabbit, the minimum fatal dose being 1.08 Gm. per kilogramme, and the chief symptom violent clonic convulsions. He experimentally demonstrated that both orthochlor- and parachlorophenol escape with the urine, in combination with sulphuric acid, and probably also with glycouronic acid, the urine becoming rapidly blackish on exposure to air, and confirmed the

observations of Kütz (A. G. P., Bd. xxx.) that the urine of dogs poisoned with the chlorphenols polarizes to the left. It would appear almost certain that the chlorphenols undergo at least partial decomposition in the organism, giving origin to hydroquinone, pyrocatechin, and other educts found after poisoning with phenol. The action of these chlorphenols upon the general system is probably practically that of phenol. As germicides these compounds were found by Nencki to be very active, the 2 per cent. solution being stronger than the 5 per cent. phenol solution, and only a little weaker than the one-thousandth sublimate solution.

In practical medicine chlorphenols have been used by Simanoffski, by Girard, and by others. According to Girard, the 2 per cent. solution is irritant to the surface of wounds, but Simanoffski asserts that even the 20 per cent. solution in glycerin is not irritant to mucous membranes. A. Spengler (*Arch. des Sci. Biolog.*, vol. iv. 1895–96) states that the parachlorophenol acts very energetically upon the tubercle bacillus, and that its 10 per cent. glycerin solution, applied locally to the larynx, causes no irritation but an anæsthesia which lasts some days and is very advantageous in the treatment of *tubercular laryngitis*. These statements have been confirmed by Simanoffski. The chlorphenols have been used in *ozæna*, *gonorrhœa*, *ulceration*, and various other surgical affections, and Girard affirms that a 1 per cent. solution affects wounds favorably, and that a 2 per cent. solution affords an excellent method of sterilizing the instruments and hands of surgeons.

The *chlorsalols*, the *salicylic esters of chlorphenols*, were also studied by Nencki and found to undergo decomposition in the intestines or system, the salicylic acid or its derivatives appearing in the urine. The antiseptic properties of these chlorsalols were found to be much greater than that of salol. Girard has used them in *doses* of from sixty to ninety grains (3.9–5.8 Gm.) a day in *cystitis* and *diarrhœa* with excellent results. Paserini has employed them in *phthisis* and in *bronchitis* by means of an inhaling apparatus, in which fifteen minims (0.9 Cc.) are placed on a piece of cotton, the patient inhaling with slow and deep inhalations from five to ten minutes daily. Usually at first some pulmonic irritation, and even for a day or two temporary exacerbation, occur, but the final results are said to be remarkable.

Menthorol, so called, is a moderately thick liquid, with an agreeable taste and the odor of parachlorophenol, which is said to be a mixture of menthol and parachlorophenol. It may be used as a local remedy in a 5 to 15 per cent. solution in the treatment of *ulcerations of the throat and lungs*.

Chroaol.—*Terpin-iodo-hydrate*, $C_{10}H_{12}.2HI$, occurs in greenish-yellow crystals, having an aromatic odor; it is insoluble in water, soluble in alcohol and glycerin, slightly soluble in ether and chloroform. It has been used externally in the treatment of *psoriasis* and other skin diseases as a dusting powder or 10 per cent. ointment.

Chrome Yellow. *Chromate of Lead. Lemon Yellow. Leipzig Yellow. Paris Yellow.* $PbCrO_4$. This is the neutral lead chromate prepared by precipitating a solution of lead nitrate with potassium chromate. It is of a beautiful lemon-yellow color. The basic lead chromate ($PbO.PbCrO_4$) possesses a red color, and is sometimes used as a pigment. *Chrome green* is either *chromium sesquioxide* or a mixture of chrome yellow and

Prussian blue. The chromates are often adulterated with lead sulphate. Duviller (*J. P. C.*, Août, 1873, 114) detects this by heating one part of the suspected pigment with a mixture of from two to three parts of nitric acid, sp. gr. 1.420, one to two parts of water, and one-fourth part of alcohol. The chromate is all dissolved, but any sulphate present remains unaffected. Lead chromate has been used by bakers for giving a rich yellow coloring to buns, and there can be no doubt of its having produced fatal poisoning in a number of cases. John Marshall has shown that its exhibition in animals is followed by an absorption, which takes place very slowly.

Chromium.—Chromium was discovered by Vauquelin in 1797. Its most common ore is *chrome iron*, consisting of ferrous oxide and chromium sesquioxide. This is not an abundant mineral, the principal source of supply being at present Asia Minor. Chromium is obtained by igniting its oxide in contact with charcoal with the aid of the electric arc; or by the more recent methods of reduction of its oxide by finely divided metallic aluminum (Goldschmidt), or by metallic silicon (Green and Wahl). It is a brittle metal, of a grayish-white color like platinum, with some lustre, and very hard, so that it scratches glass. Its sp. gr. is 6.8, atomic weight 51.7, and symbol Cr. It does not change by exposure to the air, and is with difficulty attacked by the acids. It forms with oxygen five compounds: 1, the monoxide (CrO), 2, the sesquioxide (Cr_2O_3), 3, the trioxide or chromic acid (CrO_3). Of the two others, one may be considered as a compound of the monoxide and sesquioxide ($\text{CrO} \cdot \text{Cr}_2\text{O}_3$), and the other, called *perchromic oxide*, consists of two atoms of chromium and seven of oxygen (Cr_2O_7). Chromium combines with chlorine in two proportions, forming the *dichloride* and *sesquichloride*. The chief value of chromium in the arts is as the source of potassium dichromate and of pigments, although recently it has come into extensive use as an alloy, called *ferro-chromium*, for the manufacture of chrome steel and nickel-chrome steel.

Chrysarobin Oxide.—*Chrysarobini Oxidum*. A brownish-black powder, obtained by boiling chrysarobin in water with sodium peroxide; its 5 to 10 per cent. ointment has been highly recommended by Unna in the treatment of facial, genital, and other forms of *eczema* for which chrysarobin is too irritating. It has no influence in dry eruptions.

Cichorium. *Cichorium Intybus*, L. *Chicory*. *Succory*.—A perennial herbaceous composite plant, indigenous in Europe, but naturalized in this country, where it grows in fields, and in roads along the fences. The whole plant has a bitter taste, without acrimony or any very peculiar flavor. The taste is strongest in the root and weakest in the flowers. The leaves, when young and tender, are eaten as salad. Chicory is a feeble, non-irritating tonic.

The root is much used as a substitute for or adulterant of coffee. In preparing it, Dausse recommends that the dried root should be cut into rather large and equal pieces, which are to be roasted until they lose 140 out of 500 parts. The pieces are then easily ground in a mill, and afford a yellowish-brown powder. (*Ph. Cb.*, 1850, 688.) In France alone the annual consumption of chicory root amounted in 1860 to sixteen million pounds. For methods of detection in ground coffee, see *P. J.*, 1867, 141; also Allen (*Com. Org. Anal.*, 2d ed., vol. iii., part 2, 540), and

J. R. Leebody (*Chem. News*, 1874, 243). A glucoside has been obtained from the blossoms of *Cichorium Intybus* by Nietzki (*A. Pharm.*, (3) 8, 327), to which the formula $\text{C}_{32}\text{H}_{34}\text{O}_{19}$ is assigned. On boiling with dilute acids it yields glucose and a compound, $\text{C}_{20}\text{H}_{14}\text{O}_9$. This decomposition product seems to exist in the blossoms ready formed along with the glucoside. The *garden endive* is also a species of *Cichorium*, *C. Endivia*, L.

Cicuta. *Cicuta virosa*, L. *Water Hemlock*. *Cowbane*. *Ciguë vireuse*, Fr. *Wasserschierling*, G.—A perennial, umbelliferous European plant, growing on the borders of pools and streams. It is very poisonous to most animals which feed upon it, though said to be eaten with impunity by goats and sheep. According to Wikszemski, it acts upon frogs similarly to picrotoxin, at first stimulating the convulsive centres in the medulla and producing violent general spasms, and later causing general centric paralysis. (Dragendorff, *Jahresb.*, 1875, 494.) Upon man it operates as an acrid narcotic, producing vertigo, intoxication, and convulsions, followed by general paralysis and death. (*Ibid.*) Infusion of galls is recommended as an antidote, but should not be relied on to the exclusion of emetics. When the plant causes vomiting, as it frequently does, fatal effects are less prone to ensue. It is said to be less poisonous dried than fresh; Van Ankum (*J. P. C.*, 1868, 105, 151) has shown that the active principle is a resinous, chemically indifferent substance, to which the name *cicutoin* has been given. Böhm (*A. E. P. P.*, v. 281) has since obtained this principle pure, as a thick, tenacious, amorphous substance, of acid reaction, of slight odor but disagreeable taste. The dry root yielded about 3.5 per cent., the fresh 0.2 per cent. of cicutoin. The presence of a volatile alkaloid resembling *coniine*, and termed *cicutine*, has been observed by Wittstein and Buignet. The volatile oil, obtained by distillation, was found by Simon not to be poisonous. According to Julius Trapp, it is identical with the aromatic oil of cumin seeds. (*Chem. Cb.*, 1858, 414.) On the other hand, the alcoholic extract of the dried root operated as a violent poison upon animals. (*Ann. Ch. Ph.*, xxxi. 258.) At present the plant is never used internally, and rarely externally as an anodyne poultice in local pains.

Cicuta maculata, L., *American water hemlock*, *Musquash root*, *Beaver poison*, *Spotted cowbane*. This grows in meadows and on the borders of streams throughout the United States, and is closely analogous, in botanical character and in effects, to the European species. In several instances children have been fatally poisoned by eating its root. This consists of several oblong, fleshy tubers, sometimes as long as the finger, spreading out from the base of the stem, and having an odor and taste not unlike those of parsnip. For microscopic examination of plant, see *A. J. P.*, July, 1891. *Cicuta* has been highly lauded as a specific in nervous and sick headache (*Proc. A. Ph. A.*, 1858, 253), but is rarely if ever used. J. E. Young found in the seeds an alkaloid supposed to be identical with *coniine*. (*A. J. P.*, xxvii. 294, confirmed by R. Glenk, *A. J. P.*, 1891, 328.)

In poisoning by either of these species of *Cicuta*, free vomiting should be induced as speedily as possible, and symptoms met as they arise.

Cinchonidine Salicylate. *Cinchonidinæ Salicylas*. $\text{C}_{19}\text{H}_{22}\text{N}_2\text{O} \cdot \text{C}_7\text{H}_6\text{O}_3$.—This salt occurs in needles soluble at 18° C. (64.4° F.) in 766 parts of water. It is capable of producing physiologically

the action of the quinine salts, and no doubt is a powerful antiperiodic, inferior, however, to the ordinary preparations of that alkaloid. It has been recommended and considerably used as a specific in *chronic and subacute rheumatism*, in doses of from fifteen to twenty grains (1-1.3 Gm.) a day, best given in pill or capsule.

Cinnamic Acid. *Acidum Cinnamicum*. $C_6H_5CH=CH.COOH$.—This acid occurs naturally in Peru and Tolu balsams, and is made synthetically by the reaction of acetyl chloride upon benzaldehyde, or by the action of a mixture of acetic anhydride and fused sodium acetate upon benzaldehyde. It forms colorless, lustrous plates, melting at $133^\circ C.$ ($271^\circ F.$), and is insoluble in cold water, but quite soluble in boiling water and in alcohol. Cinnamic acid is used in medicine solely in the treatment of *tuberculosis*, especially in the form of *sodium cinnamate* (*hetol*). As originally suggested by A. Landerer (*M. M. W.*, xxxv. Nos. 40, 41), this salt is to be given intravenously, and, according to Tobias, the same vein may be injected from fifty to sixty times in succession. Most extraordinary results have been claimed for the method, Landerer affirming that in the early stages of uncomplicated tuberculosis 85 per cent. of the cases can be cured. The heated controversy to which Landerer's paper gave rise has been well reviewed by W. J. Robinson (*M. A.*, 1902). It does not appear probable that the Landerer treatment will accomplish what is claimed for it, and the conclusion of Robinson that sodium cinnamate is not a direct curative agent in tuberculosis and is of no more value symptomatically than is creosote, is probably correct. The sodium cinnamate may be given by the mouth in doses of from two to three grains (0.13-0.2 Gm.). The initial intravenous dose of the intravenous treatment should not exceed one-fiftieth of a grain (0.0013 Gm.); the injection may be made every third day and the amount increased until one-third of a grain (0.021 Gm.) has been reached. A 10 per cent. solution in glycerin affords an excellent method of administration.

Citarin. *Sodium Anhydromethylenecitrate*. $(Na.O.COCH_2)_2.CO \begin{smallmatrix} CH_2 \\ CO \end{smallmatrix} O$.—A readily soluble compound which is said to liberate formaldehyde in the blood. It is asserted to be a useful remedy in cases of *uric acid gravel*, and in *gout* and *chronic rheumatism*, in doses of 30 to 45 grains (2-3 Gm.) four times a day.

Citrophen. $C_3H_4(OH)(CONH.C_6H_4.OC_2H_5)_2$. This compound of citric acid and *p*-phenetidin originated with Roos. It is a white crystalline powder, soluble in forty parts of water; its melting point is $181^\circ C.$ ($358^\circ F.$) and its ready solubility in water adapts it for hypodermic use. It is used as an antipyretic, also in *migraine* and *neuralgia*. Dose, ten to fifteen grains (0.65-1.0 Gm.).

Civet. *Zibethum*. *Civette*, Fr. *Zibeth*, G. This is an odorous substance, obtained from two animals of the genus *Viverra*; the *V. Civetta* or *civet cat* of Africa, and the *V. Zibetha*, which inhabits the East Indies. It is secreted in a cavity opening between the anus and external genitals, and is collected from animals confined for the purpose. It is semi-liquid, unctuous, yellowish, becoming brown and thicker by exposure to the air, of a very strong, peculiar odor, similar to that of musk, though less agreeable and less diffusible, and of a bitterish, subacid, disagreeable, fatty taste. When heated it becomes quite fluid,

and at a higher temperature takes fire and burns with a clear flame, leaving little residue. It is insoluble in water, and only slightly soluble in ether and cold alcohol, but heated alcohol dissolves it almost entirely, depositing it again upon cooling. It contains, among other ingredients, a volatile oil, fat, and free ammonia. In medicine it was formerly employed in lieu of castor and musk; it is now used exclusively as a perfume. For analyses of commercial samples, see *P. J.*, 1897, 101.

Clematis. *Clematis recta*, L. (*C. erecta*, L.) *Upright Virgin's Bower*. *Clématite*, Fr. *Waldrebe*, G.—A perennial European plant. The leaves and flowers have an acrid, burning taste. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing, and applied to the skin they produce inflammation and vesication; hence their old name of *flammula Jovis*. The acrimony is greatly diminished by drying. Störck found this clematis to be diuretic and diaphoretic, in doses of from one to two grains (0.065-0.13 Gm.) of the extract a day, or from thirty to forty grains (2-2.6 Gm.) of the leaves given in infusion three times a day, and to be useful, locally and internally, in *syphilitic, cancerous*, and other *foul ulcers*.

Other species of *Clematis* have the same acrid properties; among these *C. flammula*, L., or *sweet-scented virgin's bower*, which, though a native of Europe, is cultivated in our gardens, *C. vitalba*, L., or *traveller's joy*, also a native of Europe, and several indigenous species, of which *C. virginiana*, L., or *common virgin's bower*, *C. viorna*, L., or *leather flower*, and *C. crispa*, L., have been used as substitutes for *C. recta*, L. All these are climbing plants. Rochebrune (*Toxicol. Africaine*, i.) affirms that he has found in *C. flammula*, L., an alkaloid, *clematine*, two milligrammes of which will produce in the guinea pig copious and frequent urination, general tremors, great disturbance of respiration, feebleness and intermittency of the heart beat, followed in seven minutes by convulsions ending in coma and death.

From the bruised roots and stems of *C. vitalba*, L., boiled for a few moments in water to diminish their acrimony, and then digested in sweet oil for a little while, is made a preparation used locally in Europe for the *itch*. Twelve or fifteen applications are said to be usually sufficient. Gaube has found in this species an alkaloid, also named *clematine*, which forms with sulphuric acid a salt crystallizable in six-sided needles; also an acrid volatile oil analogous to mezereon in its properties, tannic acid, mucilage, and earthy salts. (*J. P. C.*, Aout, 1869.)

Clove Bark. *Cortex Caryophyllatus*. *Cassia Caryophyllata*.—Under these names two barks occur in the market. Of these the most abundant comes from the West Indies, and is derived from a tree, *Dicypellium caryophyllatum*, Nees (*Licaria guaianensis*, Aublet, *Persea caryophyllacea*, Mart.), Fam. Myrtaceæ. It is usually in cylinders, from one to two feet long by an inch in diameter, composed of numerous separate pieces rolled around one another and having a dark brown color, a pungent taste, and an odor similar to that of cloves. The second variety of clove bark occurs in fragments, resembling the other form in odor and color but softer and lighter, and supposed to be derived from *Myrtus caryophyllata* (L.) (*Eugenia caryophyllaea*, Wight), which grows in Ceylon. This clove bark has aromatic properties not unlike those of the spice from

which it derived its name, but it is much inferior and is not used in this country. Some authors have confounded with it a different bark, produced in the Moluccas, and known by the Indian name of *culilawan*. (See *Culilawan*.) For description of a false clove bark, see *A. J. P.*, vol. xv.

Cnicus. *Cnicus arvensis*, Hoffm. (*Carduus arvensis* (L.), Robs. *Cirsium arvense*, Scop.) *Canada Thistle*.—This European composite plant, to which have been attributed diaphoretic, emetic, and tonic properties, according to Herman J. Pierce (*A. J. P.*, lxviii, 1896) contains a volatile alkaloid.

Coal Tar.—When bituminous coal is subjected to dry distillation, besides the incondensable gases which serve for lighting, and the charcoal left behind as coke, which is a valuable fuel, there are formed numerous other pyrogenic products, necessarily more or less varying in character and amount, not only according to the kind of coal used, but also with the varying circumstances of the decomposing process. Most of these newly formed bodies, all of which are volatile, are condensed into a dark thick liquid or semi-liquid substance called coal tar. Formerly this was considered as refuse matter, but from it are now prepared substances of great value in the arts and in medicine. Our purpose is to give a condensed view of these substances. For greater details, see Lunge, *Coal-Tar and Ammonia*, 2d ed., London, 1887, and Sadtler's *Industrial Organic Chemistry*, 3d ed., Philadelphia, 1901, chap. xi. The composition of coal tar varies considerably with the temperature at which the distillation of the coal is effected, the yield of solid bodies and of gases being larger when the temperature is higher, while at a lower temperature the liquid portion of the tar is in increased amount. When coal tar is submitted to distillation and rectification, it yields the following products, solids, liquids, and gases, in variable proportion:

1. **Solids.**—Naphthalene, $C_{10}H_8$, methyl-naphthalene, $C_{11}H_{10}$, naphtha-ethylene and diphenyl, $C_{12}H_{10}$, fluorene, $C_{13}H_{10}$, anthracene and phenanthrene, $C_{14}H_{10}$, fluoranthene, $C_{15}H_{10}$, methyl-anthracene, $C_{15}H_{12}$, retene, $C_{15}H_{12}$, chrysene, $C_{18}H_{12}$, pyrene, $C_{16}H_{10}$, picene, $C_{22}H_{14}$, and carbazol, $C_{15}H_{11}N$.

2. **Liquids.**—These may be neutral hydrocarbons, acids, and ethers of the same, or bases. The *neutral hydrocarbons* are benzene, C_6H_6 , toluene, C_7H_8 , methyl-toluene, and iso-xylene, C_8H_{10} , pseudocumene, and mesitylene, C_9H_{12} , cymene, $C_{10}H_{14}$. The *acid constituents* are phenol, C_6H_5O , orthocresol, paracresol, and metacresol, C_7H_5O , phlorol, $C_8H_{10}O$, rosolic acid, $C_{30}H_{16}O_9$, pyrocatechin, $C_6H_3O_2$, and creosote, consisting of the methyl ethers of pyrocatechin and its homologues, $C_7H_3O_2$, $C_8H_{10}O_2$, and $C_9H_{12}O_2$. There are also present, probably in combination with the ammonia of the ammoniacal liquor, acetic, butyric, carbonic, hydrocyanic, sulphocyanic, and hydrosulphuric acids. The *bases* are ammonia, NH_3 , methylamine, CH_3NH_2 , ethylamine, $C_2H_5NH_2$, phenylamine, $C_6H_5NH_2$, pyridine, C_5H_5N , picoline, C_8H_8N , lutidine, C_7H_9N , collidine, $C_8H_{11}N$, leucoline, $C_9H_{11}N$, iridoline, $C_{10}H_{13}N$, cryptidine, $C_{11}H_{13}N$, acridine, $C_{13}H_9N$, coridine, $C_{13}H_{15}N$, rubidine, $C_{11}H_{17}N$, and viridine, $C_{12}H_{19}N$.

3. **Gases.** (1) *Illuminating gases.*—Acetylene, C_2H_2 , ethylene, C_2H_4 , propylene, C_3H_6 , butylene, C_4H_8 , allylene, C_3H_4 , crotonylene, C_4H_6 , terene, C_5H_8 , and vapors of benzene, C_6H_6 , styrolene, C_8H_8 , naphthalene, $C_{10}H_8$, methyl-naphthalene,

$C_{11}H_{10}$, fluorene, $C_{13}H_{10}$, fluoranthene, $C_{15}H_{10}$, hexane, C_6H_{14} , heptane, C_7H_{16} , and octane, C_8H_{18} .

(2) *Heating and diluting gases.*—Hydrogen, H_2 , marsh-gas (methane), CH_4 , carbon monoxide, CO .

(3) *Impurities.*—Carbon dioxide, CO_2 , ammonia, NH_3 , cyanogen, $(CN)_2$, methyl cyanide, CH_3CN , sulphocyanic acid, CN_2SH , hydrogen sulphide, H_2S , carbon disulphide, CS_2 , carbon oxysulphide, COS , and nitrogen, N_2 .

Cobalt. (Co = 58.56.)—This not very abundant metal is usually found associated with arsenic, and is rarely used in its pure condition in medicine or pharmacy. It occurs as *smaltine* or *tin-white cobalt*, *cobalt glance*, or *sulpharsenide*; *cobalt bloom*, *erythrine*, or *arsenate*; *earthy cobalt* or *wad*, a mixture of cobaltous oxide and black manganese oxide, and *spieß cobalt*, $(Co, Ni, Fe) As_2$.

Spieß cobalt is frequently employed as the source of cobalt salts, and the substance called in commerce *zaffre* is an impure cobalt arsenate, made by simply roasting the crude cobalt ores or calcining them, with access of air, and is used to give a blue color to glass, enamels, and pottery glaze. The native ore is frequently found in commerce under the name of *flystone*, and is used for poisoning flies, by roughly grinding it and putting a small quantity in a saucer with sweetened water. *Smalt* is the common name used for glass colored by fusing with oxide of cobalt, producing a blue pigment, for coloring glass, etc. The soluble salts of cobalt, particularly the *chloride* and *sulphocyanate*, have been used to impregnate paper, etc., giving it ordinarily a pink tint, indicative of the presence of moisture, while on elevation of temperature and drying the color changes to blue. Advantage has been taken of this fact to produce the so-called *barometer paper*.

A cobalt oxide, prepared by precipitating the chloride with potassium hydroxide, has been employed in *rheumatism*. It is emetic in the *dose* of 10 or 20 grains (0.65–1.3 Gm.). The salts of the metal are irritant poisons. The statement that the cobalt salts and hydrocyanic acid will form in the animal system a potassium or sodium-cobalt-cyanide and are antagonistic poisons and may be used as antidotes one for the other, is probably not correct. (See Hübner, *A. I. P.*, vol. ix.)

Cobalt Blue.—This beautiful pigment is a compound of cobalt oxide and aluminum oxide, obtained by precipitating the mixed solutions of a salt of aluminum and one of cobalt by means of an alkali, and washing, drying, and strongly calcining the precipitate. (Berzelius.) The cobalt blue of Thénard is made by heating together the hydrated cobalt sulphosphate and aluminum hydroxide. It is used in painting.

Cobweb. *Spiders' Web.* *Tela Araneæ.* Spiders' webs were formerly much used in *head-ache*, *hætic fever*, *asthma*, *hysteria*, and *nervous irritation*, but probably acted solely through the imagination. *Dose*, from ten to twenty grains (0.65–1.3 Gm.) *pro re nata*. (See *L. L.*, 1867.) Spiders' web is useful as a styptic, especially after extraction of teeth, the cavity being stuffed full of the web.

Cocculus. *Cocculus Indicus.* *Coque du Levant*, Fr. *Kokkelskörner*, *Fischkörner*, *Tollkörner*, G. *Indian Berries.* *Oriental Berries.* *Fish Berries.* *Menispermum Cocculus*, L. *Anamirta Cocculus*, Wight and Arn. *Cocculus suberosus*, DC. (Fam. *Menispermaceæ*).—This is a climbing shrub, with a suberose or corky bark, which grows along the Malabar Coast, and in Eastern

Insular and Continental India. By Roxburgh it was proved to be one source of *Cocculus*, which is, however, probably derived also from other plants, notably from the *Cocculus Plukenetii*, DC. (now *Pachygone ovata*, Miers.), of Malabar, and *C. lacunosus*, DC. (now *Anamirta paniculata*, Colebr.), of Celebes and the Moluccas. It was known to the Arabian physicians, and was imported into Europe from the Levant, from which circumstance it was called *Cocculus levanticus*. It is now brought exclusively from the East Indies.

Cocculus Indicus, as found in commerce, is roundish, somewhat kidney-shaped, about as large as a pea; having a thin, dry, blackish, wrinkled exterior coat, within which is a ligneous bivalvular shell, enclosing a whitish, oily, very bitter kernel. It is without odor, but has an intensely and permanently bitter taste. It bears some resemblance to the bayberry, but is not quite so large, and may be distinguished by the fact that in the *Cocculus Indicus* the kernel never wholly fills the shell. When the fruit is kept long, the shell is sometimes almost empty. The Edinburgh College directed that "the kernels should fill at least two-thirds of the fruit." Boullay discovered in the kernel *picrotoxin*.

A tincture of *Cocculus Indicus* is sometimes used made by macerating the ground fruit in diluted alcohol two weeks, in the proportion of four ounces in a pint. For Procter's formula for preparing a fluidextract, see *U. S. D.*, 17th ed., or *A. J. P.*, 1863.

Cocculus Indicus is used in India and elsewhere to stupefy fishes. Its powder, mixed with oil, is locally employed in the East Indies in *obstinate cutaneous affections*. An ointment of it has been used in *tinea capitis*, and to destroy vermin in the hair. Death in a child six years old, preceded by tetanic spasms and extremely contracted pupil, resulted from the application of a strong tincture of the fruit to the scalp. (*Med. Exam.*, N. S., viii. 227.) It should be used with great caution when the surface is abraded. For cases of poisoning, see Sozinsky, *Phila. Med. News*, Nov. 3, 1886; Mitchell, *Therapeutics*, Philadelphia, 1880; T. F. Haynes, *P. M. T.*, vol. xiv. 748. Moderate doses produce vertigo, weakness and headache; after large doses there are violent headache, vomiting, and epileptiform convulsions.

Cochlearia. *Cochlearia officinalis*, L. *Common Scurvy-grass.* *Herbe au Scorbut*, Fr. *Herba Cochlearia*, P. G. *Löffelkraut*, G. *Spoonwort*.—This annual or biennial cruciferous plant, is a native of the northern countries of Europe as well as the United States. The whole herb is active. It has, when fresh, a pungent, unpleasant odor if bruised, and a warm, acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil, which is separable in very small quantity by distillation with water, and is probably produced by reaction between a fixed principle in the plant and water, under the influence of myrosin acting as a ferment. (*Chem. Cb.*, 1856, 124.) The oil was at first supposed to be identical with the oil of mustard, and, later, Geiseler gave its formula $(C_5H_5)_2CS$. (See *A. J. P.*, 1859, 416.) The boiling point, according to A. W. Hofmann, is about $160^\circ C.$ ($320^\circ F.$), while that of mustard oil is $147^\circ C.$ ($296.6^\circ F.$). (*Chem. News*, 1869, 286.) According to Hofmann, the oil is a mustard oil of the butylic series, having the formula $C_8H_8NS = C_4H_9CSN$. Hofmann has made it synthetically.

Common scurvy-grass has been much used in *scurvy*, and even in *chronic rheumatism*. The fresh plant may be eaten as a salad, or used in infusion; the expressed juice has also been used.

Cocillana Bark.—The bark of a number of species of *Guarea* (Fam. *Meliaceae*) has in former times attracted attention on account of its asserted purgative and emetic properties. *G. Rusbyi* (Brit.), Rusby (*Sycocarpus Rusbyi*, Brit.), a species related to *Guarea trichiloides*, L., is supposed to yield cocillana. (*A. J. P.*, 1890, 178; *Bull. Pharm.*, 1893, 350.) The bark of this large Bolivian tree, which was discovered by H. Rusby, is believed by him (*T. G.*, 1888) to contain an alkaloid; but by John W. Eckfeldt (*Med. Bull.*, 1891) its active principle is thought to be a glucoside. In doses of from twenty to fifty grains (1.3–3.2 Gm.) the bark causes vomiting, with prostration and some purging; also, it is said, much sneezing, dull frontal headache, and discharge from the nasal mucous membrane. The therapeutic action of the drug resembles that of ipecac, although as an expectorant it is somewhat more stimulant. (See *N. Y. M. J.*, Dec. 1889, and April, 1890.) It has been used in *acute and subacute bronchitis*, *bronchial pneumonia*, *phthisis*, etc., with asserted success. Dose of the fluidextract, from eight to twenty minims (0.5–1.3 Cc.) every three or four hours.

Cælocline. *Cælocline polycarpa*, A. DC. *Xylopicium polycarpum*, O. Kze. *Unona polycarpa*, DC. *Xylopia polycarpa*, Oliver. *Berberin Tree.* *Yellow-dye Tree of Soudan*.—This small tree, of the fam. *Anonaceae*, growing in Soudan, Sierra Leone, and certain parts of Western Africa, was described by William F. Daniell. (*P. J.*, Feb. 1857.) When wounded, the tree exudes a juice which produces a yellow stain upon linen that cannot be washed out. The epidermis of the bark is greenish-gray, interrupted by occasional blackish patches; the inner layers are of a golden yellow, and very fibrous, so that they can be separated in ribbon-like bands. The bark is moderately but disagreeably bitter, and stains the saliva yellow. Water extracts its color and bitterness. Stenhouse has ascertained that it contains *berberine*. The bark is much used in Africa for dyeing yellow. In Sierra Leone it is employed topically, in powder or decoction, for *obstinate ulcers*.

Coffee. *Caffea. Semen Caffee. Café*, Fr. *Kaffee*, G. *Caffe*, It. *Cafe*, Sp. *Bun*, Ar. *Copi Cotta*, Cingalese. *Kaeva*, Malay.—*Coffea arabica*, Linn., is a small evergreen tree from fifteen to thirty feet in height. The genus *Coffea* contains a number of species which probably produce the alkaloid caffeine, but only two of which yield commercial coffee,—namely, *Coffea arabica* and *Coffea liberica*. The two species closely resemble one another, but are at once distinguished by the fact that the corolla is 4 to 5 cleft in *C. arabica* and 9 cleft in *C. liberica*. The seeds of the Liberian plant are also much larger than are those of the Arabian, are not greenish, and have the groove deeply wrinkled along its edges. The fruit of the coffee plant is a roundish berry, umbilicate at top, at first green, then red, and ultimately dark purple. It is about as large as a cherry, and contains two seeds surrounded by a paper-like membrane, and enclosed in a yellowish-purple matter. These seeds, divested of their coverings, constitute coffee.

This tree is a native of Southern Arabia and Abyssinia, and probably pervades Africa about the

same parallel of latitude as it is found growing wild in Liberia, on the western coast of the continent. About the year 1690 it was introduced by the Dutch into Java, and in 1718 into their colony of Surinam. Soon after this latter period the French succeeded in introducing it into their West India Islands, Cayenne, and the Isles of France and Bourbon.

The tree is raised from the seeds, which are sown in a soil properly prepared, and, germinating in less than a month, produce plants which, at the end of the year, are large enough to be transplanted. These are then set out in rows at suitable distances, and in three or four years begin to bear fruit. It is said that they continue productive for from thirty to forty years. Though almost always covered with flowers and fruit, they yield most largely at two seasons, and thus afford two harvests during the year. Various methods are employed for freeing the seeds from their coverings; but that considered the best is, by means of machinery, to remove the fleshy portion of the fruit, leaving the seeds surrounded only by their papery envelope, from which they are separated by peeling and winnowing mills.

The annual production of coffee for the world is about one million tons, of which the American countries produce in the neighborhood of nine-tenths, Brazil giving to commerce three-fourths of the world's supply. After South America, the chief producer of coffee is Java, that island sending into commerce nearly twice as much as the remaining Asiatic countries. The amount of coffee entering commerce from Africa is small. The character of coffee varies greatly, not only with the climate in which it is grown but with the circumstances of its cultivation and the character of the stock which produces it. The most esteemed varieties are those which are known as *Mocha* and *Java*, but probably the bulk of the berry retailed as *Mocha* or *Java* is of South American origin.¹ Coffee improves by age, losing a portion of its strength and acquiring a more agreeable flavor. It is said to be much better when allowed to ripen perfectly on the tree than as usually collected. The grains should be hard, and should readily sink in water. When soft, light, black or dark colored, or musty, they are inferior.

Mussaenda coffee, so called, is not a true coffee, but, according to Lapeyrère, is the seeds of the *Mussaenda borbonica*, or "wild orange" of the Island of Réunion, and contains from 0.3 to 0.5 per cent. of caffeine. Dunstan, however, found no alkaloid in the seeds of *M. borbonica*, while according to the botanists of Kew Gardens, the seeds which Lapeyrère examined were really derived from *Gaertnera vaginata*. (P. J., Nov. 1889.) *Senoussi coffee*, which is said to have a fine flavor, is obtained in the Soudan from the *Coffea excelsa*, which reaches the size of a tree.

Coffee has a faint, peculiar odor, and a slightly sweetish, somewhat austere taste. An analysis by Payen gives for its constituents, in 100 parts, 34 of cellulose, 12 of hygroscopic water, from 10 to 13 of fatty matter, 15.5 of glucose, with dextrin and a vegetable acid, 10 of legumin, 3.5 of *potassium and caffeine chlorogenate*, 3 of a nitrogenous body, 0.8 of free caffeine (see *Caffeina*, p. 252), 0.001 of concrete volatile oil, 0.002 of fluid volatile oil, and 6.697 of mineral substances. (J. P. C., 3e sér., x. 266.) Pfaff recognized, in the precipitate produced by lead acetate with the decoction of coffee, two peculiar principles, one resembling tannin, called *caffe-tannic acid*, and the other an acid, called by him *caffaic acid*. The latter is thought to be identical with the *chlorogenic acid* of Payen. When strongly heated, it emits the odor of roasted coffee, and it is supposed to be the principle to which the flavor of coffee as a drink is owing. A remarkable property of caffeic acid is that, when acted on by sulphuric acid and manganese dioxide, it is converted into quinone, being in this respect analogous to quinic acid. The sugar of coffee is a reducing sugar, but is almost completely caramelized in the roasting process, being reduced thereby from 8.5 per cent. to 0.5 per cent. Caffe-tannic acid has been ascertained by Hlasiwetz to be a glucoside with the formula $C_{14}H_{20}O_7$ and resolvable into glucose and a peculiar crystallizable acid, $C_8H_6O_4$, named by him *caffaic acid* (J. P. C., 1867, 307), and which may be obtained from coffee by boiling a solution of the extract with potassium hydroxide, treating the resulting liquid with sulphuric acid in excess, and extracting the caffeic acid with ether, which yields it somewhat impure by evaporation. (Ibid., January, 1868, 75.) Caffeic acid has the constitution of a dihydroxy-cinnamic acid, and on fusion with potassium hydroxide yields protocatechuic and acetic acids. The *coffee fat*, which ranges in different varieties from 14 to 21 per cent., is, when purified, white, without odor, of a buttery consistence, melting at 37.5° C. (100° F.), and becomes rancid on exposure. According to Rochleder (Wien. Akad. Ber., xxiv. 40), it contains glycerides of palmitic acid and of an acid of the composition $C_{12}H_{24}O_2$.

During the roasting process coffee swells to almost double its original volume, losing from 15 to 23 per cent. of its weight (Ph. Cb., 1850, 687), and acquires a new, peculiar odor and a bitter taste. An active empyreumatic oil (*caffeol*, $C_8H_{10}O_2$) is developed during the process, probably at the expense of a portion of the caffeine. Much of the alkaloid, however, escapes change, and a portion of it is volatilized. The excellence of the flavor of roasted coffee depends much upon the manner in which the process is conducted, and the extent to which it is carried. It should be performed in a covered vessel, over a moderate fire, and the grains should be kept in constant motion. When they have acquired a chestnut-brown color, the process should cease. If too long continued, it renders the coffee bitter and acrid, or, by reducing it to charcoal, deprives it entirely of flavor. During a severe roasting the coffee loses a portion of caffeine, which sublimates, while in a slight roasting it loses none; yet ordinary coffee for drinking, prepared by percolation, contains rather more caffeine when prepared from strongly roasted than from slightly roasted coffee, because the caffeine is more easily extracted from the former. (Herman Aubert. See A. J. P., 1873, 121.) The coffee should not be roasted long before it is used,

¹ Julian E. Walter gives the following results of the analyses of several kinds of unroasted coffee: Java, 0.89 per cent. caffeine; Liberian Java, 1.08 per cent. caffeine; Costa Rica, 1.24 per cent. caffeine; Mocha, 0.54 per cent. caffeine; Pea-berry or Penroll, 0.77 per cent. caffeine; Rio, 1.12 per cent. caffeine. (Ph. Rec., May 5, 1890, 176.) Bertrand (Bull. des Sci. Pharm., iv.) gives the following results of studies of the percentage of caffeine in various coffee berries: In *Coffea arabica* the percentage varied from 0.69 to 1.60. Of species other than the *C. arabica*, *C. canephora* was found to be the richest in alkaloid, the berries yielding 1.97 per cent., while those of the *C. humboldtiana*, Baill., were remarkable by reason of their containing a bitter principle, *cafamartin*, but no caffeine at all, the berries of *C. mauritiana* contained only 0.07 per cent.

and should not be kept in the ground state. Paul and Cownley found in preparing "low and medium roasted" coffee no perceptible loss of alkaloid, while in "over-roasted" coffee the loss amounted to one-third. The average of caffeine in roasted coffee they fix at 1.3 per cent. (*P. J.*, 1887, 822.)

The leaves of the coffee plant possess properties analogous to those of the fruit, and are extensively used by the Malays. Stenhouse found them to contain caffeine in larger proportion than the coffee bean, and also caffeic acid. The leaves are prepared for use by drying over a clear fire and then powdering by rubbing in the hands. The powder is made into an infusion like common tea. The taste is like that of tea and coffee combined. (*P. J.*, xii. 443, xiii. 207 and 382, and xvi. 1067.)

According to Paul and Cownley, a cup of coffee (3 fl. oz.), prepared by percolation through half an ounce of coffee, contains a little less than two and a half grains of caffeine. (*P. J.*, April, 1887.) The beverage, coffee, has a tendency to derange digestion and to act upon the bowels, so that in chronic or acute diarrhœa its use frequently has to be forbidden. Its habitual excessive use may give rise to troublesome dyspepsia, to cardiac irritability, or to headache, and even to vertigo. It differs so in its effects from tea, and it is said from the drink made from green coffee, as to indicate that its action depends at least in part on some substance formed during the process of roasting. In 1853 J. Lehmann found that the empyreumatic oil of coffee, *caffœone*, is active, but more recent investigations have yielded contradictory results. Hare and Marshall (*M. News*, Phila., lii.) believed that they proved the empyreumatic oil to be active. E. T. Reichert (*Ibid.*, 1890, lvi.), however, found it in dogs inactive, excepting in so far that when given intravenously it mechanically interfered with the circulation. Binz (*Ch. I. M.*, 1900, xxi.) was only able to produce with it in man a feeble nervous excitement, with restlessness, and increase in the rate and depth of respirations. Caffeone is apparently the same as the empyreumatic volatile oil, *caffœol*, which in 1880 Bernheimer (*M. Chem.*, 1) obtained from roasted coffee and believed to be a methyl derivative of saligenin; besides it and caffeine, Bernheimer obtained from the roasted coffee hydroquinone, methylamine, pyrrol, and acetone. Coffee roasters often add water and a little lard to the hot roasted coffee to increase the weight and gloss the grains. Jaeckle (*Zeitsch. f. Unters. d. Nahrungs. u. Genuss.*, 1898) failed to get *caffœol*, but in a later investigation Erdman (*A. E. P. P.*, 1902, Bd. 48) secured it as a brown oily substance with a strong odor of coffee and an acid reaction having a specific gravity of 1.0844. From this oil Erdman separates valeric acid, *furane-alcohol*, a peculiar nitrogenous substance having strongly the aroma of coffee, and various phenols; the chief constituent was *furane-alcohol*, there being at least 50 per cent. of it. Erdmann found that in doses of between 0.5 and 0.6 gramme per kilo of weight, *furane-alcohol* kills a rabbit by respiratory paralysis, and that the symptoms of poisoning are a short primary excitement, salivation, diarrhœa, respiratory depression, continuous fall of the bodily temperature, and death from collapse with respiratory failure. In man, doses of from 0.6 to 1 gramme of *furane-alcohol* increased respiratory activity without producing other symptoms. Coffee has been used in times past in various diseases, but as a medicine it has been replaced by caffeine. Roasted coffee, espe-

cially in the form of powder, has long been known to have some disinfecting and deodorizing power. Leuderitz has found that this is based upon a feeble influence exerted upon bacteria.

Syrup of coffee is prepared by Dörvault in the following manner: Treat a pound of ground roasted coffee by percolation with boiling water until two pints have passed. Evaporate eight pounds of simple syrup to six, add the infusion, and strain. Two tablespoonfuls of this syrup may be added to a cup of hot water or milk. It is also used with carbonic acid water.

Collinsonia. *Collinsonia canadensis*, L. Horse-weed. Horse-balm. Richweed. Heal-all. Stoneroot. Knot-root. Knob-weed. Guérit-tout. Baume de Cheval, Fr. *Collinsonie*, G.—A labiate plant, which grows in woods from Canada to the Carolinas. The whole plant has a strong disagreeable odor, and a warm pungent taste. C. N. Lochman (*A. J. P.*, 1885, 228) found in the root a resin, tannin, starch, mucilage, and wax; in the leaves resin, tannin, wax, and volatile oil. The alkaloid discovered by H. J. Lohmann in the root of the *Collinsonia canadensis* appears to have been a magnesium salt. (See *D. C.*, 1902.) It is tonic, astringent, diaphoretic, and diuretic. *Collinsonia* is said to be locally irritant. A decoction of the fresh root has been used in catarrh of the bladder, leucorrhœa, gravel, and dropsy.

Cologne. *Spiritus Odoratus*. U. S. 1880. *Perfumed Spirit. Eau de Cologne*, Fr. *Kölnwasser*, G.—"Oil of Bergamot, sixteen parts [or two fluidounces]; Oil of Lemon, eight parts [or one fluidounce]; Oil of Rosemary, eight parts [or one fluidounce]; Oil of Lavender Flowers, four parts [or half a fluidounce]; Oil of Orange Flowers, four parts [or half a fluidounce]; Acetic Ether, two parts [or two fluidrachms]; Water, one hundred and fifty-eight parts [or eighteen fluidounces]; Alcohol, eight hundred parts [or six and a half pints], to make one thousand parts [or about eight pints]. Dissolve the Oils and the Acetic Ether in the Alcohol, and add the Water. Set the mixture aside, in a well-closed bottle, for eight days, then filter through paper, in a well-covered funnel." U. S. 1880.

Cologne water was introduced into the Pharmacopœia of 1880, but was dropped at the 1890 revision. In our opinion a more fragrant spirit, and one more closely resembling the original, would be made if the quantity of oil of orange flowers or *neroli* were doubled.

Colubrina.—*Mabea bark*, yielded by the *Colubrina reclinata*, Brongn. (*Marcocrella reclinata*, O.Kze. Fam. Rhamnaceæ) (*Ceanothus reclinatus*, L'Herit.), of South America, has been analyzed by Elborne and Wilson, who find in it a glucoside. It is used in the West Indies as a stomachic. (See *P. J.*, April 11, 1885.)

Colutea. *Colutea arborescens*, L. Bladder Senna. *Baguenaudier*, *Séné Indigène*, Fr. *Falsche Senna*, G.—A leguminous shrub growing spontaneously in the southern and eastern parts of Europe, and cultivated in gardens. The leaflets are purgative, and in some parts of Europe are used as a substitute for senna, which is said to be sometimes adulterated with them. Barbey (*P. J.*, 1895, 261) isolated *coluteic acid*, which occurs in white crystals, insoluble in water, soluble in alcohol, chloroform, and carbon disulphide. Bladder senna is comparatively very feeble. It is administered in infusion or decoction, of which the dose is about half a pint, containing the virtues of from one to three ounces of the leaves.

Commelina.—Under the name of *Yerba del Pollo*, *Commelina tuberosa*, L., is said to be very largely used in Mexico in the treatment of internal hemorrhage, especially from the womb. From thirty to sixty grains (2.0–3.9 Gm.) of the extract may be taken in the course of one day. (See *A. J. P.*, 1897, 290.) The North American species, *Commelina communis*, L., has also had hæmostatic properties attributed to it. For chemical and microscopical study, see *A. J. P.*, July, 1898.

Commiphora. *Commiphora Berryi*, Engl. *Balsamodendron Berryi*, Arn. (Fam. Burseraceæ.) *Mulu Kilivary*.—This Indian thorn yields an abundant gum resin. (*P. J.*, Aug. 1899.)

Comptonia. *Comptonia peregrina* (L.), Coulter (*C. asplenifolia*, Gaertn.). *Sweet Fern*. *Fern-gale*. *Meadow-fern*. (Fam. Myricaceæ.)—A shrubby indigenous plant, named from the resemblance of its leaves to the spleenwort fern. It grows in thin sandy or stony woods, from Nova Scotia to North Carolina and Michigan. All parts of it possess a resinous, spicy odor. R. T. Chiles has found in it tannic and gallic acids, volatile oil, extractive, gum, resin, and a substance resembling saponin. (*A. J. P.*, xlv. 306.) H. K. Bowman found it to contain 8.20 per cent. of tannin. (*A. J. P.*, 1869, 193.) It is said to be tonic and astringent; its decoction is used in *diarrhœa*.

Condurango. *Cundurango*. *Cortex Condurango*, P.G.—This drug some years ago attracted a great deal of attention as a reputed remedy in cancerous disease, but further experience has demonstrated its uselessness. It appears, however, to be used largely in South America as an alterative in chronic syphilis, has been recognized by the German Pharmacopœia, and so merits a brief notice here. According to an official investigation (*A Report on the Origin and Therapeutic Properties of Condurango*, by Ruschenberger, Washington, 1873) made by Passed Assistant Surgeon Joseph G. Ayers, U. S. N., there are at least ten different plants known in the republic of Colombia as condurango. The variety which has been used in cancer, and which may be considered as genuine condurango, is the *condurango blanco*, the product of an asclepiadaceous vine from ten to thirty feet in length and from one to two inches in diameter. The plant, which has been named *Pseumagenetus equatoriensis*, Rusch., is the *Gonolobus Condurango* of Triana and the *Marsdenia Condurango* of G. H. Reichenbach. The bark is prepared by pounding the stem with a mallet, to separate it, and then drying it in the sun. It is from one-sixteenth to one-sixth of an inch thick, with a smooth external surface of an ash-gray color, diversified with greenish and blackish lichens. When dried on the stem the bark has a darker color. Thomas Antisell (*A. J. P.*, xliii. 289) found in it tannin, extractive matter, and a yellow resin, to which he attributes whatever of virtue the plant may possess. Vulpinus (*P. J.*, 1885, 1066) found in it *condurangin*, a substance very closely allied to vincetoxin of Tanret, and, like it, converted by warming when in concentrated solution into a tolerably stiff jelly. For Barthe's method of isolating it, see *A. J. P.*, 1892, 640. Carrara (*A. J. P.*, 1892) obtained from the so-called condurangin of commerce two principles: one insoluble in water, soluble in benzene, a light, almost white, powder, melting at from 60°–61° C. (140°–141.8° F.), and of the composition $C_{20}H_{32}O_8$. Both compounds are decomposed by acids, yielding a

brown pitchy substance, insoluble in water. According to Firbas, condurangin in solution can be recognized by freeing from alcohol with gentle warmth, precipitating with a saturated solution of sodium chloride, dissolving the precipitate in chloroform, and adding a liquid composed of equal parts of sulphuric and hydrochloric acids and alcohol. On warming, the mixture assumes a green color, which turns a beautiful greenish-blue on the addition of a trace of ferric chloride. This *Lafon reaction* is given also by adonidin, oleandrin, sapotoxin and digitoxin. *Condurango blanco* seems to have little or no positive physiological action. Gianuzzi and Bufalini, indeed, affirm that it is a convulsant, like strychnine, but Lauder Brunton has shown (*J. P.*, vol. v.) that it has no action upon frogs or rabbits unless the unfiltered solution be injected into the jugular vein, and it would seem probable that the convulsions seen by the Italian observers were the result of cerebral embolisms. Nevertheless, Kobert found condurangin to be a violent poison, causing convulsions followed by paralysis; he believes it to be a mixture of several principles. (*S. Jb.*, 1889, No. 9.) H. Chiriboga states that three drachms of the drug taken by himself in the form of decoction produced considerable activity of the circulation, copious diaphoresis, increased secretion of urine, and even some vertigo and disturbance of vision. Under the name of *Guayaquil condurango* a drug has appeared in the European markets composed of pieces of bark and fragments of woody branches, believed to be derived from an asclepiadaceous plant closely related to the genus *Gonolobus*. *Mexican condurango* is composed of split stems or thin adherent bark, and is thought to be yielded by an *Aristolochia*. For full description, see *Ph. Rund.*, May, 1888.

Condy's Fluid.—A solution made by dissolving 53 parts of potassium permanganate and 333 parts of crystallized aluminum sulphate in 777 parts of hot water.

The potassium alum, which crystallizes out when the liquid cools, is separated. The liquid is therefore a solution of the permanganate of aluminum with some aluminum sulphate. It is used as a disinfectant.

Condy asserted that in this disinfecting solution all of the available oxygen in the permanganate is utilized, whereas only 60 per cent. of the oxygen is utilized in the simple alkaline permanganate.

Connarus. *Connarus guianensis*, Lamb. *C. africanus*, G. F. W. Mey. *Seribéle*.—The seeds and root bark of this plant (Fam. Connaraceæ), from French Guinea, are used as tæniifuges; two ounces of the seeds in decoction, without straining. (Maclaud, *P. J.*, 1896, 243.)

Contrayerva. *Contrayerba*. *Contrayerve*, Fr. *Bezoarwurzel*, *Giftwurzel*, G.—The root of *Dorstenia Contrayerva*, L., of the fam. Artocarpaceæ, a native of Mexico, the West Indies, and Peru. According to Pereira and Martius, the contrayerva of the shops is the product of *D. brasiliensis*, Lam., and is brought from Brazil. The term contrayerba, in the language of the Spanish Americans, signifies counterpoison or antidote, and was applied to this root under the impression that it had the property of counteracting all kinds of poison. The probability is that the root sold as *contrayerva* is derived from several species of *Dorstenia*, among which, besides *D. Contrayerva*, two others are mentioned by Houston,

D. Houstoni, L. (not now regarded as distinct from *D. Contrayerva*, L.), and *D. drakena*, L., the former growing near Campeachy, the latter near Vera Cruz.

The root, as found in commerce, is oblong, an inch or two in length, of varying thickness, very hard, rough, and solid, of a reddish-brown color externally, and pale within; and has numerous, long, slender, yellowish fibres attached to its inferior part. The odor is aromatic; the taste warm, slightly bitterish, and pungent. The fibres have less taste and odor than the tuberous portion. The sensible properties are extracted by alcohol and boiling water. The decoction is highly mucilaginous. The tincture reddens infusion of litmus, and lets fall a precipitate on the addition of water. Mussi (*L'Orost*, 1894, 259) investigated this plant and found two substances, which he called provisionally *cajapine* and *contrayerbaine*. *Contrayerva* is a stimulant tonic and diaphoretic, and has been given in *low fevers*, *typhoid dysentery*, and *diarrhæa*, and other diseases requiring gentle stimulation.

Dose, of powdered root, half a drachm (2 Gm.). In the root of the *Gaboon ivy* (*Dorstenia klaineana*) Heckel and Schlagdenhauffen have found a coumarin-like body, *pseudocoumarin*. (*Ph. Cb.*, xliii.)

Convallaria Polygonatum, L. (*Polygonatum uniflorum*, Gilib.; now *P. officinale* (L.), All.). *Sealwort*. Solomon's Seal. *Seau de Salomon*. Genuillet, Fr. *Weisswurz*, Salomon's Siegel, G. (Fam. Liliacæ).—A perennial, herbaceous European plant, whose root is inodorous. It is said to be emetic. In former times it was used externally in *bruises*, especially those about the eyes, in *tumors*, *wounds*, and *cutaneous eruptions*, and was highly esteemed as a cosmetic. At present it is not employed. The berries and flowers are said to be acrid and poisonous. *Polygonatum multiflorum*, L. (All.) (*C. multiflora*, L.), which grows both in this country and in Europe, is analogous to the preceding in properties. (See John H. Rauch, *Im. Dis.*, 1849.)

Convolvulus. *Convolvulus Panduratus*, L. (Now *Ipomœa pandurata* (L.), Meyer.) *Wild Potato*. *Man-root*. *Man of the Earth*. *Wild Jalap*. The wild potato plant has a perennial root, and a round, purplish, procumbent or climbing stem, which twines around neighboring objects, and grows sometimes twelve feet in height. The leaves, which stand alternately on long petioles, are broad, heart-shaped at the base, entire or occasionally lobed on the sides like a guitar or violin, somewhat acuminate, deep green on the upper surface, and paler beneath. The flowers are in fascicles, upon long axillary peduncles. The calyx is smooth and awnless; the corolla tubular, campanulate, very large, white at the border, but purplish red at the base. The plant is indigenous, growing in the Eastern United States in sandy fields and along fences, and flowering from May to September. A variety with double flowers is cultivated in the gardens for the sake of ornament. The root, which was the official part, is very large, two or three feet in length, about three inches thick, branched at the bottom, externally of a brownish-yellow color, and full of longitudinal fissures, internally whitish and milky, and of a somewhat acid taste. The wild potato is feebly cathartic and diuretic (*N. Y. Journ. of Med.*, x. 375), useful in *strangury* and *calculous diseases*. Forty grains (2.6 Gm.) of the dried root are said to purge gently.

Copal.—A resinous substance brought from the East Indies, South America, and the eastern and western coasts of Africa, but most abundantly from the first mentioned source. It is the concrete juice of different trees, and is furnished by exudation. The East India copal has been ascribed to the *Vateria indica*, L. (Fam. *Dipterocarpaceæ*), (*Elaeocarpus copalliferus*, Retz., *Vateria acuminata*, Hayne), and the Brazilian, by Martius and Hayne, probably with reason, to different species of *Hymenæa* (Fam. *Leguminosæ*). There are some grounds for believing that the East India copal is also the product of a *Hymenæa*; at least a specimen of this resin was collected by Perottet from the *Hymenæa verrucosa*, Hornem. (*Trachylobium hornemannianum*, Hayne), which he found growing in the Isle of Bourbon. This tree is a native of Madagascar, and probably of the neighboring parts of Africa, and Perottet was informed that the copal of India is taken thither by the Arabs of Muscat, who obtain it from the east coast of Africa. (*J. P. C.*, 3e sér., i. 406.) It is stated by James Vaughan, who was stationed as army surgeon at Aden in Arabia, that copal is taken to that port from the African coast, opposite the island of Zanzibar, where it is said to be dug up from the earth. (*P. J.*, xii. 385.) Playfair, British consul at Zanzibar, has sent to the Kew Museum specimens of the bark of a tree, with the resin *in situ*, and specimens of the collected resin, and of the fruit of the tree, which leave little doubt that the Zanzibar copal is obtained from *Hymenæa mozambicensis* (*Trachylobium mossambicense*, Klotzsch; now *T. hornemannianum*, Hayne). In a communication from John Kirk, dated Zanzibar, March 20, 1865, it is stated that the smooth copal exported from that region is obtained from *Trachylobium mossambicense*, Klotzsch, a small tree or bush, distinguished by its rounded head of glossy leaves, with groups of white flowers at the ends of the branches. The trunk and limbs are covered with a clear resinous exudation, portions of which, after solidifying, drop to the ground and are collected, while other portions are broken from the tree. This kind of resin is always smooth, and is exported to India. Another variety, with an indented goose-flesh surface, known in the English market as *animé*, is dug from the earth, and though the product of forests now extinct, originated probably from the same tree. (*P. J.*, 1869, 654.) W. F. Daniell (*P. J.*, xvi. 369 and 423) has given an account of several varieties of copal produced on the coast and interior parts of Western Africa, from Sierra Leone to Angola and Benguela. Those from Sierra Leone, which are most highly valued for their superior hardness and transparency, are said by Daniell to be derived from the *Guibourtia copallifera* of Bennett (*Copaifera guibourtiana*, Benth.), a large leguminous tree, growing preferably in mountainous regions, and very nearly related, botanically, to the *Hymenæas* which produce copal in other regions. The drug is mostly collected, not from the tree itself, but from the beds and borders of streams, into which it is washed down, during the rains, from the hillsides, in the soil of which it had been deposited.

The commercial product known as *Manila copal*, according to Tschirch and Koch, is derived from *Agathis Dammaræ*, Rich. (*Dammaræ orientalis*, Lamb.), a conifer. It consists chiefly of free amorphous resin acids, namely, *alpha*- and *beta*-mancophthalic acid, $C_{10}H_{18}O_2$ (about eighty per

cent.), and contains besides about 12 per cent. of a resin, $C_{20}H_{32}O_2$, and about five per cent. of essential oil. The latter, when fresh, forms a liquid as clear as water, very mobile, having a pleasant odor, and the sp. gr. 0.840; it boils at from 165° to 170° C. (329° – 338° F.), and mixes in all proportions with alcohol, ether, chloroform and fatty oils.

Copal varies in appearance and properties as procured from different sources. It is in roundish, irregular, or flattish pieces, often rough over the surface, probably from the impression of sand in its soft state, colorless, yellowish, or brownish yellow, more or less transparent, very hard, with a shining, conchoidal fracture, inodorous and tasteless, of a sp. gr. varying from 1.045 to 1.139, insoluble in alcohol, partially soluble in ether, and slightly so in oil of turpentine. Some varieties unite with alcohol, if suspended in its vapor while boiling. By heat it melts and emits gases, loses from 15 to 20 per cent. of weight, and is altered so as to become more soluble in ether, alcohol, and oil of turpentine, and in this way copal varnishes are usually made. It is not a proximate principle, but consists of various resins united in different proportions. According to Unverdorben and Filhol, some five different resins can be obtained by the successive action of solvents. On the distillation of copal, an oil is obtained of the composition $C_{10}H_{16}$, boiling at from 160° to 165° C., and sp. gr. 0.965, together with an oxygenated oil, showing it to have arisen from the oxidation of various terpenes, $C_{10}H_{16}$. (For an account of the present views on the nature of copal resins see Tschirch, *Die Harze und die Harzbehälter*, Leipzig, 1900.) The East India or African copal is described by Schindler as of a globular form, softer and more transparent than the other varieties, with a surface always clear, and having an agreeable odor when heated. It is readily and freely dissolved by the oils of turpentine and rosemary when pure, but not by these fluids when rendered resinous by age. It is more readily fusible than the others, and makes the best varnish. The West India copal is in flat pieces, seldom weighing more than three ounces, rarely containing insects, very hard, of a rough appearance, of a yellowish color, and without odor or taste. It is much less readily dissolved by oil of turpentine than the East India variety, swells but does not dissolve in oil of rosemary, and is slightly soluble in absolute alcohol. A third kind, probably also American, is in convex or concave pieces, about a pound in weight, often containing insects and other impurities. In solubility it resembles the last mentioned variety, in fusibility it is intermediate between it and the East Indian, and is altogether inferior. (P. J., 1850.) The African or Sierra Leone copal is described by Daniell as occurring "in small round tears, or irregular conical and smooth nodulated masses, seldom exceeding in size an ordinary duck egg. They are covered, to a greater or less extent, by a peculiar white efflorescence, which increases by age. Their color graduates from a pale green to a lemon or dull yellow." (*Ibid.*, xvi. 369.) Welwitsch states that this drug is mostly found in sandy soil, in the hilly districts, along the whole coast of Angola, where its prevalence coincides with that of *Adansonia digitata*, L. (Fam. Malvaceæ.) It is dug from the earth, or found in spots where it has been collected by the washing of the rains, or laid bare by earth-falls, and the quantity annually collected in this region, and

exported from Benguela, was at one time very large. The surface, like that described by Daniell, is covered with a whitish earthy crust, sometimes exhibiting veins or network, probably produced by attrition in their conveyance by floods. (A. J. P., 1866.)

Inhabane copal has been shown to be the product of *Copaifera gorskiana*, Benth. (Fam. Leguminosæ), and seeds sent to Kew Gardens in 1886 germinated, and the plant has been widely introduced into both the East and West Indies, and into Australia. (P. J., xix. 508.)

Crude and scraped copal are known in the market; the former of a dull opaque appearance externally, the latter much clearer and more transparent, in consequence of being deprived of its outer coat. The process of *scraping* is said to consist in the removal of the exterior portion by means of an alkaline solution, which readily dissolves copal. This resin is used chiefly in making varnishes. H. Violette states (A. J. P., 1863, 140) that certain varieties of copal used for varnish, which are not naturally soluble in ether, oil of turpentine, benzine, petroleum, etc., become soluble in these menstrua, whether cold or hot, by being heated in close vessels to the temperature of from 176.7° to 204.4° C. (350° to 400° F.), and thus yield excellent varnishes without loss of matter; and the same resin, heated as above with one-third of linseed oil and three-fourths of oil of turpentine, gives directly a clear, limpid, slightly yellowish varnish, fit for the most delicate uses. (J. P. C., 4e sér., iv. 284.) Edison found aniline oil a good solvent for copal.

Copper Acetate. *Cupri Acetas*, U. S. 1880. $Cu(C_2H_3O_2)_2 \cdot 2H_2O = 198.14$. *Crystallized verdigris*. *Crystals of Venus*. *Verdet*, *Cristaux de Vénus*, Fr. *Essigsäures Kupfer*, *Aerugo crystallisata*, *Crystallisirter Grünspan*, G.—This salt may be prepared by dissolving verdigris in acetic acid, or by precipitating a concentrated solution of lead acetate with copper sulphate. It is the normal cupric acetate, as distinguished from the basic salt. "Deep-green, prismatic crystals, yielding a bright green powder, efflorescent on exposure to air, odorless, having a nauseating, metallic taste and an acid reaction. Soluble in 15 parts of water and in 135 parts of alcohol at 15° C. (59° F.), in 5 parts of boiling water and in 14 parts of boiling alcohol. When heated above 100° C. (212° F.), the salt loses its water of crystallization, and at a temperature above 200° C. (392° F.), it is gradually decomposed. The aqueous solution of the salt has a bluish-green color, which is rendered deep blue by an excess of ammonia. On heating the salt with sulphuric acid, acetic vapors are evolved. If the aqueous solution of the salt be treated with hydrogen sulphide until all the copper is precipitated, the filtrate should leave no residue on evaporation (alkalies, alkaline earths, and iron). If the aqueous solution be heated to boiling with solution of soda in excess, it will yield a filtrate which should not be clouded by hydrogen sulphide (absence of lead, zinc)." U. S. 1880.

Verdigris. *Impure Subacetate of Copper*, U. S. 1870. *Copper Subacetate*. *Viride Aeris*, *Aerugo*, Lat.; *Acétate de Cuivre brut*, *Sous-acétate de Cuivre*, *Vert-de-gris*, *Acétate basique de Cuivre*, *Verdet gris*, Fr. *Grünspan*, *Spangrün*, *Basisches Essigsäures Kupfer*, *Kupferoxyd*, G.; *Verde Rame*, It.; *Cardenillo*, Sp.—This basic salt is prepared in the south of France, more particularly in the neighborhood of Montpellier. It is also manufac-

tured in Great Britain and Sweden. In France the process is conducted in the following manner. Sheets of copper are stratified with the residue of the grape after the expression of the juice in making wine, and are allowed to remain in this state for a month or six weeks. At the end of this time the plates are found coated with a considerable quantity of verdigris. This is scraped off, and the plates are then replaced as at first, to be further acted on. The scrapings thus obtained form a paste, which is afterwards well beaten with wooden mallets, and packed in oblong leathern sacks, about ten inches in length by eight in breadth, in which it is dried in the sun, until the loaf of verdigris, as it is called, attains the proper degree of hardness. The rationale of the process is easily understood. The juice of the grape refuse undergoes the acetous fermentation, and the acetic acid attacking the copper forms the subacetate. In England a purer verdigris is prepared by alternating copper plates with pieces of woollen cloth steeped in pyroligneous acid. Verdigris comes to this country exclusively from France, being imported principally from Bordeaux and Marseilles. The importation for 1904 amounted to 59,843 lbs., valued at \$7,750. It occurs in masses of a pale green color, and composed of a multitude of minute silky crystals. Sometimes, however, it occurs of a bright blue color. Its taste is coppery. It is insoluble in alcohol, and, by the action of water, a portion of it is resolved into the neutral acetate which dissolves, and the tribasic acetate which remains behind in the form of a dark green powder, gradually becoming black. It is hence evident that, when verdigris is prepared by levigation with water, it is altered in its nature. When verdigris is acted on by sulphuric acid, it is decomposed, vapors of acetic acid being evolved, easily recognizable by their vinegar odor. It is almost entirely soluble in ammonia, and dissolves in hydrochloric and diluted sulphuric acids, with the exception of impurities, which should not exceed 5 per cent. When of good quality, it has a lively green color, is free from black or white spots, and is dry and difficult to break. The green rust, called in popular language verdigris, with which copper vessels are very frequently coated, when not kept clean, is a copper carbonate, and should not be confounded with true verdigris. Verdigris, apart from its impurities, is a variable mixture of the basic copper acetates.

The blue variety has approximately the composition $(C_2H_3O_2)_2Cu.Cu(OH)_2 + 5H_2O$. When treated with water it is gradually decomposed into two parts, according to the reaction:

The latter of these products constitutes the green variety of verdigris. (Flückiger, *Pharm. Chem.*, 758.) The local and general action of verdigris upon the animal economy and the treatment of its poisoning are the same as those of copper sulphate. It is not used internally.¹

Copper Ammonio-sulphate. *Cuprum Ammoniatum*. Ammoniated Copper. *Cuprum Sulfuricum Ammoniatum*. *Sulfate de Cuivre ammoniacal*, *Cuivre ammoniacal*, Fr. *Schwefelsaures Kupferoxyd-Ammoniak*, *Ammoniakalisches Kupfersulfat*, G.—“Take of Copper Sulphate half a troy-ounce; Ammonium Carbonate three hundred and sixty grains. Rub them together in a glass mortar until effervescence ceases. Then wrap the Ammoniated Copper in bibulous paper, dry it with a gentle heat, and keep it in a well-stopped glass bottle.” *U. S.* 1870.

When the two salts above mentioned are rubbed together, a reaction takes place between them, attended with the elimination of the water of crystallization of the copper sulphate, which renders the mass moist, and with the simultaneous escape of carbon dioxide gas from the ammonium carbonate (sesquicarbonate), which occasions an effervescence. The color is at the same time altered, passing from the light blue of the powdered copper sulphate to a beautiful deep azure. The nature of the chemical changes which take place in the formation of what is commonly called “ammoniated copper” depends somewhat upon the conditions of action. When anhydrous cupric sulphate is exposed to the action of dry ammonia gas, the mass becomes heated, and a deep blue powder, $CuSO_4 + 5NH_3$, results, which on exposure to the air is capable of exchanging the 5 molecules of ammonia for a corresponding amount of water. If, however, one part of powdered cupric sulphate be added to three parts of ammonia solution (sp. gr. 0.960), and after the subsidence of any ferric hydroxide present as impurity, six parts of alcohol be added to the clear liquid, crystals will be formed of the composition $Cu(NH_3)_4SO_4 + H_2O$. If this preparation be allowed to remain exposed to the air, it will lose ammonia and water, and be changed into a mixture of basic sulphates. Ammoniated copper sulphate loses two molecules of NH_3 and the one molecule of water at $150^\circ C.$ ($302^\circ F.$), and at $260^\circ C.$ ($500^\circ F.$), only anhydrous sulphate remains, which frequently, however, contains cuprous oxide.

This salt has a beautiful deep azure-blue color, a strong ammoniacal odor, and a styptic, metallic taste. It is soluble in water, and the solution has an alkaline reaction on vegetable colors; but, unless there is excess of ammonium sesquicarbonate, the solution deposits copper subsulphate if much diluted. When exposed to the air it parts with ammonia, and is said to be ultimately converted into ammonium sulphate and copper carbonate. This change is apt to occur, to a greater or less extent, while it is drying. It should not, therefore, be prepared in large quantities at a time, and should be kept in well-closed bottles. By heat the whole of it is dissipated, except the copper oxide. Arsenic trioxide precipitates a green copper arse-

forms, consisting of the red or suboxide of copper (cuprous oxide); and that at the end of the process little or none of the metallic salt remains. This happens especially when granular or old honey is employed. (Harley, *P. J.*, xl. 357.) The change is owing to the decomposition of the cupric oxide by the grape sugar of the honey, converting it into cuprous oxide. The inference is that, in making the preparation, so as to fulfil the objects of the original prescription, simple syrup should be used. It was formerly employed, either undiluted or mixed with some mild ointment, to destroy fungous granulations or to repress their growth. In the latter state it acts as a stimulant to flabby, indolent, and ill-conditioned ulcers; and, largely diluted with water, it has been used as a gargle in venereal ulcerations of the mouth and throat. It is sometimes also applied undiluted, by means of a camel's-hair brush,

¹ *Lintimentum Eruptivis*, *Mel Egyptiacum*, *Unguentum Egyptiacum*.—This is an old preparation, formerly official in Great Britain. The following is the process for it given in the old London Pharmacopœia: “Take of Verdigris (Subacetate of Copper), in powder, an ounce; Vinegar seven fluidounces; Honey fourteen ounces. Dissolve the Verdigris in the Vinegar, and strain through linen; then gradually add the Honey and boil down to a proper consistence.” The ounces used here are troyounces. It sometimes happens, during the boiling of the acetic solution of the verdigris, that a red deposit rapidly

nite from its solution. Solutions of potassium and sodium hydroxides, lime water, and the acids are incompatible with it. Ammoniated copper was formerly much employed in *epilepsy, chorea, hysteria*, etc. It is at present very seldom exhibited. In overdoses it produces vomiting, and the poisonous effects which result from the other preparations of copper. *Dose*, in pill or solution, a quarter or half a grain (0.016–0.032 Gm.), twice a day, and gradually increased to four or five grains (0.26 or 0.32 Gm.).

Copper Arsenite. *Cupri Arsenis. Scheele's Green.*—This salt was brought forward for the purpose of treating *diarrhœa* on the homœopathic principle, in the *Symptomen-Codex* of Jahn, in 1865, and has been greatly lauded by John Aulde and other regular practitioners in the treatment of *diarrhœa, enterocolitis, cholera morbus, and dysentery*. It is to be given in doses of from one-three-thousandth to one-two-thousandth of a grain (0.000022–0.000033 Gm.), at intervals of from ten to twenty minutes, until some effect is produced. It does not seem to be sustaining its first reputation. According to H. A. Hare copper arsenite is a valuable remedy in *anæmia*; *dose*, one-twentieth grain (0.003 Gm.).

Copper Iodide. *Cupri Iodidum. Cuprous Iodide. Kupferjodür.* G.—A white powder, insoluble in diluted acids and in water; soluble in ammonia water and solution of potassium iodide. Made by adding a solution of potassium iodide to a solution of copper and iron sulphates.

Copper Nitrate. *Cupri Nitras. Br. 1885. Cupric Nitrate.* $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$.—"May be obtained by dissolving copper in diluted nitric acid and evaporating the solution until crystallization takes place on cooling to a temperature not lower than 70° F. (21.1° C.)." *Br. 1885.* This salt was introduced in the 1885 revision of the British Pharmacopœia, to be dropped in 1898. As obtained by the above process, the crystals are prismatic and of a deep blue color, and very deliquescent and corrosive. At a temperature below 70° F. (21.1° C.), with one-third of its weight of water it forms tabular crystals which have the composition $\text{Cu}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$. The addition of a very little more water causes the crystals to form a styptic and caustic fluid. The diluted aqueous solution should show only a faintly acid reaction to litmus-paper. This salt has the physiological and medicinal properties of copper sulphate, and may be used in the same dose.

Copper Nucleinate. *Cuprol.*—This salt is a greenish powder and is said to contain 6 per cent. of the metal and to be readily soluble in hot water and not to be thrown out of its solution by alkalies and not to precipitate with albuminous liquids. It is used in 10 per cent. solution with one-half per cent. of chlorotone as a preservative. It has been highly recommended in the treatment of *trachoma* and other conditions of the conjunctiva. The assertion is made that it has greater penetrating powers and produces less irritation than ordinary salts of copper. (Von Sicherer, *Die Ophthalm.* Kt., 1901.)

Copper Oxide, Black. *Cupri Oxidum Nigrum. Cuprum Oxydatum. Oxyde noir de Cuivre, Safran de Vénus.* Fr. *Kupferoxyd.* G.—*Cupric oxide*, CuO , is obtained most conveniently by heating to redness the nitrate. This oxide, in the form of ointment, made by mixing four parts with thirty of lard, has been locally used twice a day to remove *chronic indurations of the glands*. (Hoppe, *Ann. Thér.*, 1855.) It is also asserted

to be an active *ténicide* of very feeble toxic power. It is given by Dörr in doses of one and a half grains (0.096 Gm.) four times a day for several days, the last dose followed by castor oil. (See *Ther. Geg.*, 1901.)

Copper Phenolsulphonate. *Cupri Phenolsulphonas. Copper Sulphocarbonate. Paraphenolsulphosaures Kupfer.* G. $(\text{C}_6\text{H}_4(\text{OH})\text{SO}_3)_2\text{Cu} + 5\text{H}_2\text{O}$.—Green prismatic crystals soluble in water and alcohol. Made by reaction between copper sulphate and barium phenolsulphonate. Used externally as an antiseptic (1 to 100 or 200) solution in *gonorrhœa* and *blennorrhœa*.

Coptis. *Goldthread. Coptide.* Fr. *Gelbe (Kleinste) Niesswurze*, G.—The slender, bright yellow root of the ranunculaceous plant *Coptis trifolia* (L.), Salisb., was formerly official in the U. S. Pharmacopœia. It inhabits the northern region of this continent and of Asia, and is found in Greenland and Iceland. It delights in the dark shady swamps and cold morasses of northern latitudes and alpine regions, and abounds in Canada and in the hilly districts of the Northern United States.

Dried goldthread, as brought into the market, is in loosely matted masses, consisting of the long, thread-like, orange-yellow roots, frequently interlaced, and mingled with the leaves and stems of the plant. It is without odor, and has a purely bitter taste, unattended with aroma or astringency. It imparts a bitterness and yellow color to water and alcohol, but most perfectly to the latter, with which it forms a bright yellow tincture. The infusion is precipitated by silver nitrate and lead acetate. (Bigelow.) It affords no evidence of containing either resin, gum, or tannin. The plant undoubtedly contains *berberine*, which, according to F. F. Mayer (*A. J. P.*, 1863) and E. Z. Gross (*Ibid.*, 1873), is associated with another alkaloid. Gross states that *coptine* differs from *berberine* in its colorless crystals, and by forming with *mercuric potassium iodide* (Mayer's reagent) a crystalline instead of flocculent precipitate. See also John J. Schulz (*A. J. P.*, 1884, 261). C. W. Burr detected starch in *Coptis trifolia*. (*A. J. P.*, 1884, 31.) Goldthread is a simple tonic bitter, bearing a close resemblance to quassia in its mode of action, and applicable to all cases in which that medicine is prescribed, though, from its higher price, not likely to come into general use as a substitute. In New England it is employed as a local application in *aphthous ulcerations* of the mouth, but it probably has no other virtues in this complaint than such as are common to the simple bitters. It may be given in substance, infusion, or tincture. The dose of the powder is from ten to thirty grains (0.65–2.0 Gm.), or of a tincture made with an ounce of the root to a pint of diluted alcohol, one fluidrachm (3.75 Cc.).

The *Coptis Teeta* of Wallich, which grows in the mountainous regions bordering on Assam, is much used as a tonic by the natives and by the Chinese. It is analogous in properties to *C. trifolia*, and is said to contain 8½ per cent. of *berberine*. It has been brought into use in British India. It is highly commended by Twining as a stomachic tonic. (*P. J.*, 1870, 161.) *Coptis anemonifolia*, Lieb. and Zucc., is said to contain *berberine*, and has been used in Japan in *intestinal catarrh*. (*Sei-i-Kwai*, 1892.)

Coral. *Corail.* Fr. *Koralle.* G.—The solid mesodermal calcareous skeletons of the coral polyps, *anthozoa*, were formerly used in medicine, but

have passed out of vogue. Their chief constituent is calcium carbonate, colored by ferric oxide, and united with more or less animal matter.

Corallin. Pæonin.—A coloring or dyeing material, derived from *rosolic acid* or *aurin* ($C_{19}H_{14}O_8$), which is itself derived from *phenol* or *carbolic acid* by the joint action of sulphuric and oxalic acids upon it. It is formed by exposing together rosolic acid and alcoholic ammonia to a heat of $149^{\circ} C.$ ($300.2^{\circ} F.$), and is considered to be an intermediate product between pararosanine and pararosolic acid. A solid substance is thus obtained, in scales of a peony redness, with reflected green or dull yellow rays, almost insoluble in water, soluble in alcohol and the fixed oils. Ambrose Tardieu, having met with some extraordinary cases of a severe vesicular eruption upon the feet, attended with violent inflammation and swelling, and with general febrile symptoms, attributed to the wearing of red socks, found that these socks yielded nothing to water, cold or hot, feebly acidulated or alkaline, but did give up their red coloring matter to boiling alcohol of 85° . By evaporating the alcoholic solution thus made, an extract was obtained, whose alcoholic solution given hypodermically caused death in various lower animals. An alcoholic solution of pure corallin was then injected. A dog was killed by twenty centigrammes (about three grains), a rabbit by half the quantity, and a frog by five centigrammes, or less than a grain. In the dog and rabbit there was violent purgation, with intense fever and progressive prostration, and the leg of the side in which the injection had been made was very painful. After death the neighborhood of the wound was found suppurating, the stomach sound, and the intestines distended, with signs of violent inflammation of the mucous membrane; the liver presented evidences of fatty degeneration and the lungs appeared as if dyed by the scarlet coloring matter. Roussin succeeded in extracting a portion of the coloring matter from the lungs and liver, and dyeing with it a skein of silk. These experiments are very interesting from a medico-legal point of view, as corallin might be readily detected in this way, if at any time, accidentally or otherwise, the cause of fatal results. Hitherto the effects on the human subject have been confined to the painful cutaneous affection, which has been so satisfactorily traced to contact of the skin with the silk fabrics dyed with it; but even in these cases there were serious constitutional symptoms, as fever, headache, giddiness, and nausea. (*J. P. C.*, 1859, 262.)

Local poisoning may be caused by aniline red as well as by corallin. The two colors may be distinguished in tissues. *Aniline red* disappears very rapidly by contact with ammonia; but the color reappears by the addition of an acid, or by the evaporation of the alkali. *Corallin red* is not dissolved by cold water, yields a slight color to boiling water, but rapidly disappears from the tissue under the action of boiling alcohol. Alkalies brighten the color without changing it; acids precipitate the coloring matter in yellow flakes. (*Ibid.*, 1869, 371.) Some observers later than Tardieu believe that pure corallin is not poisonous, and that the symptoms have been produced by arsenic or other contaminating substances. (See *M. T. G.*, 1869, 421; *P. J.*, 2d ser., xi, 360; also *N. Y. M. J.*, 1870, 599; *N. R.*, i, 288.)

Corallorhiza. *Corallorhiza odontorhiza* (Willd.), Nutt. *Coral-root*. (Fam. Orchidaceæ).—This is a parasitic leafless herb, sending up from a coral-like rhizome a simple scape or flower stem, from six

to sixteen inches high, furnished with sheaths instead of leaves, of a light brown or purplish color, and bearing small, greenish-brown flowers in a long spike. The plant grows throughout the United States east of the Mississippi. The rhizome is the part used. It is much branched and toothed, and of a brown color, and from its resemblance to coral gave name to the plant. It has a strong peculiar odor, and an astringent bitterish taste. It is much valued by the eclectics as an energetic diaphoretic, destitute of general stimulant properties. It is given in fevers; dose of powder, thirty grains (2 Gm.) every two hours.

Cordol. *Tribromsalol*. $C_6H_4.OHCOO.C_6H_2Br_3$. A white, tasteless, and odorless powder, insoluble in water, ether, and alcohol, freely soluble in chloroform and glacial acetic acid. *Cordyl* or *acetyl tribromsalol* is insoluble in water, and occurs in the form of fine white needles. *Cordeine* or *methyl tribromsalol* occurs in small white crystals, which are insoluble in water, but soluble in alcohol and chloroform. Cordol, cordyl, and cordeine are said to be hypnotics which have the advantage of being almost tasteless. The dose of either is from eight to fifteen grains (0.5–1.0 Gm.).

Coriaria. *Coriaria myrtifolia*, L. *Currier's Sumach*. *Redoul*, *Sumach des Corroyeurs*, Fr. *Gerberstrauch*, G. (Fam. Coriariaceæ).—This is a shrub growing wild in Southern Europe, which is sometimes cultivated in gardens on account of its handsome foliage. The leaves, which are used for dyeing black, were at one time employed to a considerable extent in France in the adulteration of senna. The fruit, resembling berries in form, are black, and about the size of a pea. Both these and the leaves are poisonous in large doses, and several instances of death are on record from eating the fruit. (Mérat and De Lens.) Riban has discovered in the fruit *coriamyrtin*. This is in the form of white crystals, inodorous, excessively bitter, and extremely poisonous. It fuses at $220^{\circ} C.$ ($428^{\circ} F.$), and crystallizes again on cooling. It is but slightly soluble in water, hot or cold, but freely so in alcohol, ether, chloroform, and benzol. Its composition is represented by the formula $C_{30}H_{38}O_{10}$. It ranks with the glucosides, as when boiled with diluted hydrochloric acid at least three decomposition products are formed, of which one separates in yellow flocks, while the solution reduces alkaline copper solutions. About three grains caused in a dog vomiting, severe convulsions, and death in an hour and a quarter. Riban obtained it by treating the juice of the fresh or an infusion of the dried fruit and leaves at first with lead acetate, then with hydrogen sulphide to throw down the lead, concentrating the filtered liquid to a syrupy consistence, and agitating this with ether, which extracted the poison, and yielded it on evaporation. (*J. P. C.*, 1864, 487.)

Tolocopetate, a Mexican drug, is said to be the product of a *Coriaria*, probably *C. myrtifolia*, containing *coriarin* and *coriamyrtin*, and to be actively poisonous.

Toot-poison. *Tu-tu*.—In New Zealand a poisonous plant, known as the *toot-plant*, has proved very destructive to the domestic animals. W. Lauder Lindsay found it to be the *Coriaria ruscifolia* of Linnaeus (*C. sarmentosa*, Forst.), and in its action on the system to be an irritant narcotic. For an elaborate account of the *toot-plant*, and its poisonous effects, see *Brit. and For. Med.-Chir. Rev.*, 1865, 153, and 1868, 465. From these it appears that more than one species of *Coriaria*

inhabit New Zealand, *C. thymifolia*, Humb. et Bonpl., and *C. angustissima*, Hook. f., besides the *ruscifolia*; though Lindsay appears to think that the two former may be merely varieties of the third. It is not only cattle that are poisoned by the plant, but not infrequently also children, and occasionally even an adult. The cattle are probably, in general, poisoned by eating the young shoots. W. S. Key attributes poisonous qualities to an oil (*Chem. News*, 1890, xxii.), but it has been shown by T. Hill Easterfield and B. C. Aston that the three New Zealand species of coriaria contain a glucoside, *tutin*, $C_{17}H_{26}O_7$, which is not identical with coriamyrtin, and which, according to Marshall, is toxic especially to the medulla oblongata and the basal ganglia of the brain. (*Proc. Chem. Soc.*, xvi. 213.) It is affirmed by T. H. Hustwick (*P. J.*, vol. xv. 22) that goats are not poisoned by the tu-tu, and have even been used to eradicate the plant by browsing, also that the berries when ripe are not only not poisonous to man, but, if care is taken to reject the seeds, are a grateful and refreshing fruit. The prominent symptoms of the poisoning in man are giddiness, stupor, and coma, with or without delirium or convulsions. Occasionally the delirium resembles that of alcoholic intoxication, in other instances approaches that of acute mania, and is attended with violent muscular action. Loss of memory is characteristic of the convalescence.

Cork. *Suber. Liège*, Fr. *Kork*, G.—The great use made of this substance in pharmacy and the arts justifies a brief notice of it. It is chiefly produced by *Quercus Suber*, L. (Fam. Cupuliferæ), but is obtained also from the *Q. occidentalis*, F. Gay, and from *Q. pseudosuber*, Santi. It consists of the exterior layers of the bark beneath the epidermis, which acquire in these species an extraordinary development, becoming thick, and of that peculiar spongy consistence which characterizes cork. The tree begins to yield cork when fifteen or sixteen years old, and every six or eight years furnishes a fresh supply, even for a century and a half, before it perishes, that interval of time being required for the renewal of the suberose layers by the living portions of the bark beneath. There are four constituent layers of the bark: the epidermis, within this the cork, next the cellular envelope, and lastly the liber which lies upon the wood. Each of these increases year by year; but the cork thus naturally produced is not valued. The commercial product is obtained by an artificial process. The exterior layers are removed, and the liber exposed. In the interior of this, at a variable distance from the surface, a layer of the proper cork is now formed, apparently by a change in the substance of the liber, the outer portions of which perish, while annually a new layer is added to the cork already existing, until it acquires a thickness which will justify its removal. Incisions are made in such a way that the cork is removed in large concave plates, which are then flattened under pressure, and dried. At present cork comes into commerce from Portugal, Spain, France, Italy, Tunis, Algeria, and Morocco. About one million of quartels of it are said to be produced annually.

A cork has recently come into the United States commerce from Nicaragua. It has been found by E. F. D. Baker to be obtained from the roots of the *Anona*, a tree closely resembling in appearance the ordinary cottonwood of the United States.

In selecting cork for use, those parts should be preferred which are soft and of uniform consist-

ence, and in the choice of the larger plates those should be selected which are thick, flexible, elastic, finely porous, and of a reddish color. Boiling hot alcohol extracts from rasped cork tissue some 10 per cent. of soluble principles. From the hot alcohol solution a substance crystallizes which was first noticed by Chevreul under the name of *cerin*. According to Kugler (*Dissertation on Suberin*, Halle, 1884), besides cellulose and lignocellulose, cork contains two constituents, *cerin*, to which he gives the formula $C_{20}H_{32}O$, and *suberin*, which is a fat, and contains stearic acid and *phellonic acid*, $C_{22}H_{42}O_3$. This constituent, suberin, prevents the penetration of liquid into the cork, and is only extracted by alcoholic alkali solutions. When treated with nitric acid, cork yields a peculiar acid, which has been denominated *suberic acid*. This is a dibasic acid homologous with oxalic acid, and has the formula $C_8H_{14}O_4$. It is formed by the oxidation of many other substances, such as the oils from linseed, castor bean, cocoa nut, almond, spermaceti, etc.

Stanislaus Martin has called attention in France to the use of refuse corks in Paris, where they are collected by the scavengers, and sold to persons whose business it is to revive them, recutting such as are of unsuitable shape, filling up the interstices with mastic, and covering them over with some powder which may give them a fresh and proper appearance. In consequence of the high price of cork, those which are thus prepared over again are said to be used in the bottling of beverages. Corks are sometimes bleached with sulphurous acid, and the odor of hydrogen sulphide has been noticed in prescriptions which have been compounded, when such corks have been used in the dispensing bottle. (*P. J.*, 1881, 1080.) Mohr has found that old corks may be regenerated by allowing them to soak for twenty-four hours in hot water, washing well several times, allowing to stand for a few hours in a mixture of one part of hydrochloric acid and fifteen parts of hot water, and finally washing well in pure water. (See also *A. J. P.*, 1875, 467.) It is easy to conceive that a cork at one time used to enclose arsenical or other deadly solution may become saturated with the poison, and afterwards impart enough of it to another liquid, if not to produce dangerous effects on the health, at least to give to tests evidence of its presence, and thus lead to serious suspicions. No cork, therefore, which has been used in a bottle containing a poisonous substance should be employed a second time.

Cornus. *Dogwood*. *Ecorce de Cornouiller à grandes fleurs*, Fr. *Grossblüthige Cornelrinde*, G.—Under the name of *Cornus*, the U. S. Pharmacopœia formerly recognized the bark of the root of *Cornus florida*, L. (Fam. Cornacæ), the only American species of the genus which attains the size of a tree.

The barks of two other indigenous dogwoods are sometimes substituted for that of *C. florida*, L. Each of these is a shrub with opposite leaves, the flowers in flat spreading cymes, and the fruit globular and blue. *C. circinata*, L'Her., is further distinguished by its branches being greenish and warty; its leaves round-oval, abruptly pointed, and woolly underneath. *C. Anomum*, Mill. (*C. sericea*, L.), is to be recognized by its purplish branches, and by the fact that the branchlets, stalks, and lower surface of the elliptical pointed leaves are silky and downy.

These dogwoods are found in all portions of the United States east of the Mississippi.

Dogwood bark was used many years ago as an antiperiodic in *intermittent fever*, but it is only a feeble, astringent tonic. Formerly from one to two ounces of the powder were given in the interval between the paroxysms of intermittent fever, and the U. S. Pharmacopeia recognized the fluid-extract, and gave in the edition of 1880 the following formula for its production: "Cornus, in No. 60 powder, one hundred grammes [or fifty ounces av.]; Glycerin, twenty grammes [or seven and a half fluidounces]; Diluted Alcohol, a sufficient quantity, to make one hundred cubic centimeters [or three pints]. Mix the Glycerin with fifty ounces [or forty-one fluidounces] of Diluted Alcohol. Moisten the powder with thirty grammes [or fifteen fluidounces] of the mixture, and pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterward, Diluted Alcohol, until the Cornus is exhausted. Reserve the first eighty-five cubic centimeters [or forty fluidounces] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure one hundred cubic centimeters [or three pints]." U. S. 1880. The dose of this fluidextract was from half a fluidrachm to a fluidrachm (1.8-3.75 Gm.).

Cornutine Citrate. *Cornutine Citras.*—*Cornutine citrate* of commerce is a blackish-brown powder. According to Kobert, Lewitzky, Krohl, and others, the alkaloid cornutine is the active principle of ergot. For practical purposes the citrate is preferable on account of the difficulty of solution of cornutine. Lewitzky affirms that, in doses of from one-twelfth to one-sixth grain (0.005-0.01 Gm.) cornutine administered by the mouth is very active and certain in its influence upon *uterine contraction* and in congestive and hemorrhagic *metritis*. This is confirmed by Thompson and Krohl. Meisel alleges that it is a powerful remedy in *hemorrhage* and *paralytic spermatorrhoea*. The citrate may be given hypodermically.

Coronilla. *Coronilla scorpioides*, Koch.—In 1886 (Nancy Thesis) Cardot announced that the *Coronilla scorpioides* (Medic.), Koch, a papilionaceous plant of Southern France, is an active cardiac poison. In 1889 Schlagdenhauffen and Reeb (*R. G. Clin. Therap.*, July, 1889) isolated a glucoside, *coronillin*, to which they assigned the formula $C_{11}H_{12}O_6$. It was a yellowish powder, soluble in water, acetone, and amyl alcohol; slightly soluble in chloroform and ether. Heated with diluted hydrochloric acid an amorphous resin was separated, *coronillein*. This also occurs as a yellow powder, but is not bitter to taste. It is insoluble in water, but dissolves in alcohol, acetone, and chloroform. The physiological studies by Gley, by Schlagdenhauffen and Reeb, and by Prevost, some years since, led to the conclusion that coronillein acts upon the heart in a manner similar to digitalis, and to the practical trials of the drug as a succedaneum for digitalis. The most recent researches are those of Luigi Maramaldi (*R. T.*, cxxxvi.), who finds as the result of elaborate experiments that coronillin in small dose lowers the rate and increases the energy of the cardiac beats; while in larger doses it increases the systolic contraction up to the point of permanent ventricular

spasm, these results being due to a direct influence upon the cardiac muscular fibre, which increases gradually its tonicity so that it becomes less extensible during diastole, contracts with more than the normal force, and finally fixes itself in systolic arrest. This action upon the heart is accompanied by increase in the arterial pressure, followed after a time by lowering of the pressure, which apparently is the result of failure of diastole, causing the amount of blood forced out of the heart at each systole to be insufficient to fill the arteries. The inhibitory intracardiac ganglia are said to be at first stimulated, afterwards paralyzed. The drug also depresses the spinal cord, and lowers the respiratory movements by an action which is believed by Maramaldi to be partly centric and partly peripheral. Death is produced by cardiac arrest. The toxic lethal dose for the frog weighing about 30 Gm. was found by Maramaldi to be from 0.0004 to 0.0005 Gm.; for the dog to be 0.0005 Gm. per kilo (1 to 2,000,000) of the animal's weight.

Locally, coronillin appears to be actively irritant. In Maramaldi's experiments it failed to assert its physiological action when administered to the dog by the mouth, a result believed by the investigator to be due to its decomposition by the acid in the stomach. It is claimed for it that it is an excellent cardiac tonic, superior to digitalis in that it is very rapidly eliminated. As it has been found by various clinicians to be active in man when given by the mouth, it is probable that the comparative feebleness of human gastric juice permits of its absorption unchanged. The dose given by various clinicians has varied greatly, from three to five grains (0.2-0.32 Gm.)—Spillemann—downward. These differences probably depend upon differences in purity of the various samples used; of the commercial coronillin the dose is commonly stated at present to be one and one-half grains (0.096 Gm.) from four to six times a day, but it must be noted that Schlagdenhauffen affirms that three-fourths of a grain (0.048 Gm.) is a toxic dose. *Coronilla* varia of Europe also probably contains coronillin. (V. Poulet, *B. G. T.*, 1891.)

Coryl is a mixture of methyl chloride and ethyl chloride. It has been used in dentistry and minor surgery as an anesthetic.

Corylus. *Corylus rostrata*, Ait. *Beaked Hazel*. This is a small indigenous shrub of the fam. Betulaceæ, growing especially in mountainous districts. The nut is invested with a scaly involucre, projecting beyond it like a beak, and thickly covered with short spicules like those of *Mucuna pruriens*, DC. (Fam. Leguminosæ.) These spicules have been employed by Huebener as an anthelmintic. They operate in the same way as cowhage, and may be administered in the same manner and dose. (See *A. J. P.*, xiv. 280.)

Cosaprin, $C_6H_4 \begin{matrix} \text{SO}_2\text{Na} (1) \\ \text{NH} - \text{CO} \cdot \text{CH}_3 (4) \end{matrix}$, is the acetyl derivative of sodium parasulphanilate, and is obtained by the reaction of acetic anhydride upon the sodium salt of *parasulphanilic acid*. Cosaprin forms a greenish-white finely crystalline tasteless powder of a mild saline taste, freely soluble in water, difficultly soluble in alcohol, and almost insoluble in ether, forming a colorless solution with a weak acid reaction. It has been studied by V. Vámosy and Fenyvessy (*Th. M.*, 1897), who find that it resembles phenacetin very closely in its action, but is characterized by the promptness and shortness of its influence.

Cosciniu. Br. Add.—The dried stem of *Cosciniu fenestratum* (Gaertn.), Colebr. (*Menispermum fenestratum*, Gaertn.). The stem of this menispermaceous plant has long been used in Ceylon and Southern India as a yellow dye and bitter tonic, and has found its way into Europe under the names of *false columba* and *tree turmeric*. It almost certainly contains berberine and is an efficient stomachic. The Br. Add. recognizes an *infusion* (*Infusum Coscini*, Br. Add.), dose, one-half to one fluidounce (15–30 Cc.); a *concentrated solution* (*Liquor Coscini Concentratus*, Br. Add.), dose, one-half to one fluidrachm (1.8–3.75 Cc.); and a *tincture* (*Tinctura Coscini*, Br. Add.), dose, one-half to one fluidrachm (1.8–3.75 Cc.).

Cotarnine Hydrochloride. *Stypticin*. $C_{12}H_{15}NO_4.HCl$.—This salt occurs in commerce in yellow crystals, readily soluble in water and alcohol. It is made by oxidizing narcotine. The fact that the only chemical difference between hydrastinine and cotarnine is that in the latter OCH_3 is substituted for one atom of hydrogen led Freund to suggest the substitution of cotarnine in *dysmenorrhœa* and *menorrhagia* for hydrastinine, and on trial Gottschalk found that it was powerfully hæmostatic and also analgesic. Falk (*Th. M.*, vol. x. 1896) found that cotarnine produces in frogs paralysis by depression of the spinal cord, and in warm blooded animals a slightly narcotic condition followed by paralysis, results of an influence respectively upon the cerebral cortex and the spinal cord. On the circulation it has no direct influence. On the respiratory centres it so acts as to produce a primary stimulation, soon followed after the large dose by lessened respiratory movements, and finally central asphyxia and death.

There is a great mass of clinical evidence that cotarnine is a valuable remedy in the arrest of *excessive menstruation* and also that it is very effective in pulmonic and other internal hemorrhages and as a local hæmostatic. Cotarnine gauze and purified cotton saturated with cotarnine have been greatly praised by dentists and surgeons. In excessive menstruation one-half grain (0.032 Gm.) may be given three or four times a day for four days before the expected discharge, the dose being increased to one grain (0.065 Gm.) when the menstruation appears. In hæmoptysis three grains (0.2 Gm.) may be given at once subcutaneously, and repeated in half an hour, if required.

Coto Bark.—In the years 1873 and 1874 a bark bearing this name appeared in the London drug market, coming from Bolivia. Its botanical origin still remains unknown. Under the name of *coto-coto*, the bark of a rubiaceous plant (*Paliourea densiflora*) is employed in Brazil in *rheumatism*. Whether this be the Bolivian plant or not is very uncertain.

Coto bark occurs in pieces a foot or more long, from three to four inches wide, and from one-half to three-quarters of an inch thick. The outer surface is irregular, often looking as though it had been shaved or split off, and in other parts covered with a fine adherent epidermis free from lichens; the inner surface also is irregular, with numerous rather closely placed, longitudinal projecting bark bundles.

The general color approaches cinnamon-brown; upon fresh cross section the bark is seen to be filled with yellowish spots, except in the outer portions. The odor is aromatic, and much more apparent if bruised; the taste hot, and somewhat

aromatic; the powder is very pungent to the nostrils. The microscope shows the outer bark to be composed of thin-walled, colorless, parenchymatous cells, containing starch granules, with numerous yellowish sclerenchymatous cells joined into groups. The inner bark contains numerous yellow bark cells, mostly joined into bundles of from twenty to fifty. For microscopic structure, see *P. J.*, vi. 301, also *Ph. Era*, May, 1888. The coto bark which we have seen in the American market conforms with the original description, but other barks are said to pass under the name. The most important of these is the so-called *Paracoto bark*, which is stated to differ from the true coto bark chiefly in its having a less pungent but more agreeably spicy taste, and being marked with deep whitish furrows upon its surface. Wittstein found in coto bark a volatile alkaloid, a pungent aromatic volatile oil, yellowish-brown soft resin, brown hard resin, starch, gum, sugar, calcium oxalate, tannin, and formic, butyric, and acetic acids. (*A. Pharm.*, iii. 4, 219.) Jobst and Hesse obtained a crystallizable body, *cotoin*, from true coto bark, by making an ethereal extract from the powdered bark, treating this with warm petroleum benzin, and allowing the mixture to stand until clear. The clear liquid yields cotoin in crystals on spontaneous evaporation. The oily resinous residue contains considerable cotoin, which may be obtained by boiling with milk of lime and adding to the solution hydrochloric acid. After twenty-four hours the clear liquid will be found studded with large, glistening, laminated crystals of cotoin, of a pale yellow color. Cotoin, $C_{14}H_{12}O_4$, is sparingly soluble in cold water, more soluble in hot water, insoluble in petroleum benzin, very soluble in alcohol, chloroform, benzol, acetone, and carbon disulphide. Nitric acid becomes blood-red in contact with cotoin, sulphuric acid is colored brownish-yellow, and ferric chloride blackens a dilute solution of cotoin.

Paracotoin, $C_{15}H_{12}O_8$, is extracted from paracoto bark, in which it exists associated with *oxy-leucotin*, $C_{34}H_{32}O_{12}$, *leucotin*, $C_{34}H_{32}O_{10}$, *hydrocotoin*, $C_{15}H_{14}O_4$, and *dibenzoylhydrocotoin*, $C_{32}H_{32}O_8$. Paracotoin may be distinguished from cotoin by giving no reaction with ferric chloride. *Piperonylic acid* (*methyleneprotocatechuic acid*), $C_8H_6O_4$, is present in both barks. Coto bark is decidedly irritating; its powder, rubbed upon the skin, is said to produce heat and redness, and, according to Burkart, fifteen grains (1.0 Gm.) taken into the stomach produce persistent burning pain, followed by repeated vomiting. The remedy was first introduced as serviceable in *diarrhœa*, and seems to have established its reputation. Although observers are not explicit upon this point, it is evident that when there is a tendency to acute inflammation it must be used with great caution. The *paracoto bark* is said to resemble it in its action, but to be much less powerful. The fluid-extract and tincture are very eligible preparations, the former made with alcohol in the usual way, and the tincture 1 part in 10 of alcohol, which may be given in from five to fifteen-minim (0.3–0.9 Cc.) doses every two or three hours.

The active principle, cotoin, is given by Dr. Burkart in doses of three-quarters of a grain (0.048 Gm.) every two or three hours. He states that he could detect it in the urine from four to six hours after the ingestion of the dose. Balz (Tokio, Japan) is said to have treated *cholera* successfully by hypodermic injections of three grains (0.2 Gm.) of paracotoin. Oxy-leucotin, leucotin, and hydro-

cotin are very feeble. The value of cotin in the treatment of *diarrhœa* has been confirmed by various clinicians. It has been used in catarrhal diarrhœas and the diarrhœas of tubercular ulceration, of typhoid fever, and of other conditions. (See B. G. T., vol. xi. 167.) It does appear to have some special effect upon the alimentary canal, as, according to Pribram (*Prager Med. Wochens.*, 1880) and Albertoni (*A. E. P. P.*, xvii. 293), it markedly lessens the excretion of indican. Albertoni also believes that it actively dilates the abdominal vessels and thereby hastens absorption, and Bibrana, that it is an antiseptic. It is not probable that cotin has any general action upon the system, and Jobst found that even fifteen grains (1.0 Gm.) injected hypodermically into the rabbit produced no other than local symptoms. *Dose*, of cotin, from one to three grains (0.065–0.2 Gm.); of fluidextract of coto, from five to twenty minims (0.3–1.3 Cc.), four to six times a day.

Cotula. U. S. 1870. *Mayweed. Wild Chamomile. Dog Chamomile. Camomille puante. Maroute. Herbe de camomille puante. Herbe de maroute.* Fr. *Hunds-Kamille, Hunds-Kamillenkraut, Stinkende Kamille, G. Camomilla fetida, Cotula.* It. *Manzanilla loca, Sp. Herba Chamomilla Fœtida. Anthemis Cotula, L. Maruta Cotula, De Cand.*—The mayweed is an annual composite plant, which grows abundantly both in the United States and in Europe. In this country it is found in the vicinity of inhabited places, growing among rubbish, along the sides of roads, and in waste grounds. W. H. Warner found in the flowers volatile oil, oxalic, valeric, and tannic acids, coloring matter, acrid fatty matter, bitter extractive, and salts of potassium, calcium, magnesium, and iron. (*A. J. P.*, 1858, 390.) Patone (1859) claimed to have found an alkaloid, *anthemidine*, and a crystallizable bitter acid, *anthemidic acid*, but his results have not been confirmed. The whole plant has a strong, disagreeable odor, and a warm, bitter taste, and imparts these properties to water.

The medicinal properties of this species of *Anthemis* are essentially the same as those of chamomile, for which it may be substituted, but its disagreeable odor is an obstacle to its general use. On the continent of Europe it has been given in *hysteria* as an antispasmodic. It has also been thought to be emmenagogue. It is said to have the property of vesicating, if applied to the surface fresh and bruised. The whole plant is active, but the flowers, being less disagreeable than the leaves, are preferred for internal use. The remedy is best administered in the state of infusion.

Cotyledon Umbilicus, L. Navelwort. Pennywort. *Cotylet, Nombil de Venus, Fr. Nabelkraut, G.*—This is a perennial, herbaceous, succulent plant, of the fam. *Crassulaceæ*. The plant is a native of England, where it grows upon old walls and rocks, and dry sandy banks.

According to Flétet, it contains *trimethylamine*, combined with an unknown acid. When the powder of the plant is exposed to the air, it attracts moisture, and exhales a disagreeable odor strikingly analogous to that of fish, and an extract treated with a fixed alkali disengages, even in the cold, an odor which, at first ammoniacal, soon acquires the fishy character referred to. The plant contains cellulose, starch, glucose, mucilage, chlorophyll, yellow coloring matter, a volatile oil smelling like sandarac, tannin, iron, and salts of potassium, sodium, calcium, and iron, with 0.9 per

cent. of nitre, and 95 per cent. of water. (*Ann. Thér.*, 1865, 125.) It has been highly lauded in *epilepsy* (for references, see 16th edition U. S. D.), but it has very feeble and uncertain therapeutic properties. *Dose*, of fresh juice, from one-half to one fluidounce (15–30 Cc.), two or three times a day; of fluidextract, one fluidrachm (3.75 Cc.); of dry extract, five grains (0.32 Gm.); to be increased and given steadily for months.

Cow Tree. *Palo de Vaca. Palo de Leche.*—The milky juice of the *Brosimum galactodendron*, D. Don (Fam. *Urticacæ*), is much used in South America instead of cream in tea and coffee, etc. It is obtained by making incisions in the tree, is white and viscous, turns sour on exposure to the air, and deposits a caseous substance. According to the analysis of Boussingault, its composition varies very much, but it always contains a large percentage of fatty matters (32.2 per cent.), and much less casein, albumen, sugar, and phosphates. (*P. J.*, ix. 679.)

Crab Orchard Salt.—A mild, saline purgative, obtained by evaporating the waters of springs at Crab Orchard, Lincoln County, Kentucky. Its principal active ingredients are the magnesium, sodium, and potassium sulphates; it contains also a little iron and lithium. In its crude form it is not wholly soluble, and sometimes it is purified by dissolving and straining through flannel, and evaporating. As thus prepared, it is white, and as a purgative is about 20 per cent. stronger than the crude salt. It, however, lacks the tonic properties of the latter. According to R. Peter, the composition of the dry salt is: magnesium sulphate, 63.19 per cent.; sodium chloride, 4.77; sodium sulphate, 4.20; potassium sulphate, 1.80; calcium sulphate, 2.54; calcium, magnesium, and iron carbonates, and silica, 0.89; water of crystallization and loss, 22.61; total, 100.00. *Dose* from one to two teaspoonfuls. (See *A. J. P.*, 1874, 5.)

Crabs' Claws. *Chela Cancrorum.*—These, finely powdered, were formerly official. In the 100 parts are 60 parts of calcium carbonate and 14 of calcium phosphate, with 26 of animal matter.

Crabstones. *Lapilli Cancrorum. Crabs' Eyes. Oculi (Calculi) Cancrorum. Yeux (Pierres) d'Ecrevisses.* Fr. *Krebsaugen, Krebssteine, G.* Concretions found in the stomach, one on each side, of the European crawfish, at the time the animal is about to change its shell; chiefly procured in the province of Astrakhan, in European Russia. The crawfish are bruised with wooden mallets and laid up in heaps to putrefy. The animal remains are then washed away, and the stones picked out. They are inodorous, insipid bodies, somewhat hemispherical in shape, of a whitish or reddish color, hard and stony consistence, and laminated texture. They are very variable in size, weighing from one to twelve grains each. They effervesce with acids, and, without dissolving, become converted, owing to the animal matter which they contain, into a soft transparent mass, retaining the original shape of the stone. By this character they are distinguished from counterfeit stones, which are sometimes fabricated of chalk mixed with mucilaginous substances. They consist of calcium carbonate and phosphate, cemented together by animal matter. Crabstones have been used as an absorbent and antacid, given in the same dose as prepared chalk.

Cranberries. Fruit of *Oxycoccus macrocarpus* (Ait.), Pers. (*Vaccinium macrocarpon*, Aiton.) (Fam. *Vacciniacæ*).—These familiar berries, so well known as an article of diet, have come into

notice as a source of citric acid. For method, see *J. P. C.*, 4e sér., xviii. 439. The leaves of the *Vaccinium Vitis-idaea* (L.) have been studied by Edo Claassen (*A. J. P.*, 1886) and A. M. Karger (*P. J.*, vol. lxx.). They contain *arbutin*, *hydroquinone*, and *tannin*. *Benzoic acid* has also been recognized as normally present in small amounts. In the cranberry Edo Claassen found an uncrystallizable glucoside, *oxycoccin*.

Creosote Albuminate. *Creosotum Albuminatum.* *Nutrincresosote*.—A yellow-gray powder, which is said to contain 40 per cent. of pure creosote and to be free from irritant action.

Creosote Carbonate. *Creosotum Carbonicum.* *Cresotal*.—This is a mixture of the phenol-carbonates of the several constituents of creosote, and is obtained by the action of carbon oxychloride upon the phenol-sodium compounds of creosote. It is a thick, oleaginous, pale yellow, almost tasteless liquid, soluble in ethyl and methyl alcohol, chloroform, in benzene, and in fatty oils; insoluble in water; having an oleaginous taste, which after a time suggests that of creosote. Its specific gravity is from 1.165 to 1.168. It contains 92 per cent. of pure creosote and is analogous to guaiacol carbonate.

It is stated that this substance is free from the poisonous activity of creosote and is well tolerated by the digestive apparatus, and that it has the activity of creosote in *phthisis* and other forms of *tuberculosis*, in chronic *bronchitis* and *enteritis*, *ulcerations*, *intestinal indigestion*, and in various other derangements of the alimentary canal. It is decomposed in the system, as the odor of creosote is imparted to the breath and the urine becomes blackish from the appearance in it of the educts from creosote. In *phthisis* and in chronic *bronchitis* creosote carbonate is much used in doses of fifteen to thirty minims (0.9–1.8 Cc.) up to two to four fluidrachms (7.5–15.0 Cc.) a day, administered in capsule, emulsion, or preferably in milk, sometimes added to cod liver oil. Fifteen fluidrachms (66 Cc.) a day are asserted to have been given without any unpleasant symptoms. It has been used to a considerable extent hypodermically. Before the administration it should be warmed, so as to obtain complete fluidity.

Creosote Iodide. *Creosotide*.—A product obtained by causing iodine to enter into combination with the cresol constituents of beechwood creosote. It contains approximately 25 per cent. of its weight of iodine. It is an amorphous brownish powder, practically insoluble in water and having a faint characteristic odor and taste. It is prescribed in incipient *tuberculosis* with alleged good results; also in *asthma* and as a gastric and intestinal antiseptic. *Dose*, one-fourth to one-half grain (0.016–0.032 Gm.) three or four times a day.

Creosote Oleate. *Creosoti Oleas.* *Oelsaures Creosot*, *Oleokreosot*, G.—An oily liquid, light yellowish in color, almost odorless, but with slight creosote taste, insoluble in water and almost so in 90 per cent. alcohol, freely soluble in absolute alcohol, ether, chloroform, benzene and fixed and volatile oils.

It is used for the same purposes as creosote in doses of from one to three fluidrachms (3.75 to 11.25 Cc.).

Creosote Phosphate. *Creosoti Phosphas.* *Phosote*.—A combination of creosote and phosphoric acid, in the form of a syrupy, colorless liquid, with almost no odor or taste of creosote. It contains about 80 per cent. of creosote and 20 per cent. of phosphoric anhydride.

The *dose* is two fluidrachms (7.5 Cc.) given in 24 hours, and it is said to be one of the best forms in which to administer creosote. *Creosote Phosphate* and *Creosote Tannophosphate* (*Taphosote*) have also been introduced as antiseptics.

Creosote Tannate. *Creosotum Tannicum.* *Creosal.* *Tannosal*.—The tannic acid ester of creosote. It is obtained by heating equal quantities of beechwood creosote and pure tannin to 80° C. (176° F.) and adding gradually phosphorus oxychloride and purifying the product. It is soluble in water, alcohol, glycerin, and acetone and occurs as a dark brown hygroscopic powder. It is astringent and antiseptic, and may be given in daily doses of forty-five grains (3 Gm.), representing 26 grains (1.8 Gm.) of creosote.

Creosote Valerate. *Creosotum Valeras.* (*Eosote*).—A mixture of the valeric esters of the phenols contained in creosote. It forms a rather mobile oily liquid, boiling at about 240° C. (464° F.), and soluble in alcohol and ether. This substance as an internal medicine is practically identical with the creosote carbonate. *Dose*, three grains (0.2 Gm.).

Crescentia. *Crescentia Cujete*, L.—The fruit of this South American plant (Fam. Bignoniaceæ) has been found by Gustav Peckoldt to contain *crescentinic acid* and a blue coloring matter allied to indigo. (*Ph. Rund.*, Aug. 1884.)

Cresin. *Cresapol*.—Made by dissolving 25 per cent. of cresol in 75 per cent. of a solution of sodium cresoxyl-acetate. A brown, clear liquid soluble in alcohol and water. It is said to be less toxic than phenol. Cresin is used in $\frac{1}{2}$ to 1 per cent. solution as a disinfectant for wounds.

Cresol Iodide. *Iodocresol.* *Traumamol*. C_6H_3I . $(CH_3)OH$.—This is formed by the action of potassium iodide solution upon an emulsion of cresol and water. It contains but one atom of iodine, while Iosophan or cresol triiodide contains three atoms, and, consequently, a higher percentage of iodine. It is a violet-red, odorless, amorphous powder; insoluble in water, acids, and alcohol; dissolving with difficulty in ether, readily in alkaline solutions, and freely in chloroform. It contains 55 per cent. of iodine, and has been commended as powerfully antiseptic, non-irritant, and having local anæsthetic properties. It is used locally in *syphilitic* and other *ulcers*, *eczema*, especially when attended with much discharge, *intertrigo*, and various other skin diseases. Also as a substitute for iodoform in surgery. In *herpes* a 10 per cent. traumamol collodium has been found very useful, and a 5 to 10 per cent. traumamol zinc ointment has been highly commended. Pure traumamol may also be used as a dusting powder.

Cresol Naphthol.—A brown, viscous, tar-like liquid, insoluble in but emulsifying with water. Guinard states that it is a very active germicide, and that it is impossible to produce poisoning in the lower animals by giving by the mouth, largely on account of its inducing vomiting at once. Its aqueous solution, like that of other creolin products, has the disadvantage of depositing in wounds.

Cresol Preparations.—On account of the insolubility of cresol, various compounds were some time since put upon the market. The most important of these are *bacillool*, *creolin*, *lysol*, *solveol*, *paracresol*, and *tricrosol*. These compounds are not essentially different from the *Liquor Cresolis Compositus*, U. S.

Creolin is said to be an emulsion of cresol, obtained by means of rosin soap. There are in the market at least two sets of preparations, the one

of German the other of English origin. An analysis of Creolin-Pearson, published by Pfrenger (*A. Pharm.*, 1890, 701), gives: phenols, 2.67; hydrocarbons, 44.94; organic bases, 2.76; sodium, 1.45; resin, 32.45; sulphur, 0.248; chlorine, 0.14; water (by difference), 5.34. The phenols consisted of ortho- and meta-cresol, with traces of phenol and the oxyleucols; the hydrocarbons, of the higher homologues of benzene, with naphthalene and anthracene; the bases belonged to the quinoline group. Creolin forms a milky emulsion or mixture with water; with chloroform, ether, and absolute alcohol it mixes in all proportions. It is sometimes called *cresoline* or *sanatol*.

Medicinal Properties.—According to Jessner, the first report upon creolin was that of F. von Esmarch (*Ob. B.*, Bd. ii., Nos. 10 and 11), who stated, as the result of experiments made with creolin and phenol upon putrefactive bacteria and upon the bacteria of *cholera*, *typhoid fever*, and *anthrax*, that it was much more powerful than phenol as a germicide, except in the case of the anthrax bacillus. It is claimed for creolin that it is not poisonous. Jessner (*L. M. R.*, Aug. 1889) gave eight ounces (249 Gm.) to a cow without any effect; and daily doses of one hundred and twenty grains (7.7 Gm.) were given to a man without any bad general symptoms, or any noticeable effect except decrease of intestinal gases and limitation of the putrefactive processes in the intestine. The urine also required longer than usual for ammoniacal fermentation. In a case reported by Kortüm, nine hundred grains (60 Gm.) are said to have been taken without bad effects, while in a case reported by S. Korach (*D. M. W.*, xxi. 1895), seventy-five grammes of creolin were taken for suicidal purposes. Although both coma and collapse, with complete loss of corneal reflexes, and tracheal râles, also vomiting and diarrhoea, occurred, the patient finally recovered without permanent injury. It is true that Neudörfer (*Internat. Klinisch. Rundsch.*, April, 1888) has shown that injection of creolin into the venous circulation of dogs produces a marked effect, but this may be mechanical, connected with the insolubility of the remedy. Fatal human poisoning by creolin has, however, occurred. Bitter (*B. M. J.*, 1890) has seen restlessness, anxiety, nausea, amblyopia, and a tendency to syncope, with a peculiar strong taste of tea or smoke, produced by the drug. The urine in some of these cases was dark and strongly albuminous, evidently acute nephritis having set in. Fliesburg (*Northwestern Lancet*, Dec. 1891) details a case of a three-weeks-old babe who was killed by thirty drops of undiluted creolin, the chief symptoms being those of violent irritation of the mouth and upper respiratory and digestive tracts.

Compared with other antiseptics, creolin seems to be innocuous. Externally, according to Neudörfer, the solution of 1 to 5 per 1000 is non-poisonous and very antiseptic. He claims that it does not affect the hands or instruments of the surgeon, and is the best of the antiseptics for practical purposes. *Creolin gauze*, as usually sold, contains from 5 to 10 per cent. of the creolin; Neudörfer believes that the 1 per cent. is sufficiently strong. He recommends, especially for local use, the creolin in a powder combined with asbestos, in the proportion of 5 to 100, and for the disinfection of catheters and other instruments, a 33 per cent. solution with olive oil.

Internally, creolin is probably a very important remedy when it is desired to check fermentation in the alimentary canal. Locally applied, it has been largely used with great success in the treatment of *scabies*, in the form of a 5 per cent. ointment with vaseline. In *ammoniacal cystitis*, washing out the bladder with a half per cent. solution of creolin has yielded excellent results. It also seems to be a very effective local application in the treatment of *acute* and *chronic dysentery*, and also in the *cholera morbus* of children. In the case of adults, large enemas of a one-half of one per cent. solution may be used; in the case of infants the strength should be about one-half of this. As a local application in *gonorrhœa*, creolin has been used with alleged most excellent results, both in the form of bougies containing half a grain of creolin, and the injection of creolin dissolved in olive oil (1 in 3). For washing out the uterus after *labor*, the strength of the creolin solution should be 1 per cent.

Creolin is recommended by Jaksch as a deodorant to iodoform; a mixture of from 1 to 2 per cent. of creolin with iodoform produces a compound *creolin-iodoform* of a faint aromatic odor, soluble in alcohol and ether, and believed to possess the therapeutic properties of iodoform. Water removes from it the creolin and leaves the iodoform.

Ethylenediaminetriecresol or *kresamin* is a mixture of triecresol with ethylenediamine. It is a colorless aqueous liquid, having a phenol-like odor, and after standing in the air becomes of a light yellow color without losing disinfecting power. According to H. Eckstein, it is an exceedingly powerful antiseptic, especially adapted to the preserving of specimens for microscopic use. As a local application the same author has found it very valuable in those cases of *eczema* in which there was a pronounced secondary infection of the skin, and also in *sycoosis* and similar parasitic diseases. Bandages of it wet with a solution of from 1:4000 to 1:400 were kept applied to the part. In *lupus* and some similar conditions local protracted baths of from three to twelve hours' duration, with a concentration of 1:4000, were found efficacious. From 10 to 15 per cent. ointments of it were also employed.

Lysol is made by dissolving the fraction of tar oil which boils between 190° and 200° C. (374°–392° F.) in fat, and subsequently saponifying by the addition of alkali, in the presence of alcohol; it is a brown, oily looking, clear liquid, with a feebly aromatic, creosote-like odor. It is described as containing 50 per cent. of cresols, miscible with water (forming a clear, saponaceous, frothing liquid), also with alcohol, petroleum spirit or petroleum benzin, chloroform, carbon disulphide, and glycerin. To the aqueous solution of the saponified cresols and fat may be added any desired quantity of the higher phenols.

Lysol was introduced as a disinfectant by V. Gerlach (*Zeit. für Hygiene*, June, 1891), who, as the result of an elaborate research, found that both in pure cultures and in mixed masses of pathogenetic bacteria it is more powerful as a germicide than is phenol or creolin; that its 1 per cent. solution has a soapy feeling, and can be used for the purpose of disinfecting the hands without the use of soap; that for the purposes of disinfecting sputa and stools it is by far the most powerful of the germicides; that it is free from irritating properties, unless in strong solution, so that wounds may be sprayed with a 3

per cent. solution and absolutely disinfected; and that comparatively it is much less poisonous than phenol, corrosive sublimate, or even creolin; 1 or 2 per cent. solutions were said to produce some slight transient burning when brought in contact with the mucous membrane. According to Lemke and Straube, a 0.3 per cent. solution will, in fifteen minutes, completely arrest the development of pus organisms, and a 0.5 per cent. solution even remove the odor of putrefying flesh. The value of lysol as an antiseptic has been confirmed by Vulpis, by Michelsen, and other surgeons, and there can be little doubt as to its applicability to the needs of antiseptics, although various surgeons seem to find it a little more irritating than at first stated, and some condemn it as not superior to the older antiseptics. Szuman (*Nowiny Lekarskie*, June, 1891) affirms that a solution stronger than 1 per cent. produces irritation, and that even two parts to a thousand are irritating to the bladder. It does not injure metallic instruments to an appreciable extent or those made of rubber, but celluloid articles are said to become friable and useless under its action. A large number of cases are on record in which lysol has caused severe and sometimes fatal poisoning. The symptoms have been similar to those of phenol poisoning, with marked fall of temperature, and in many cases hemorrhagic nephritis. Indeed, lysol is probably, in proportion to its remedial activity, as toxic as is phenol. H. Cramer has reported death from its vaginal use. (*Centrab. f. Gynækol.*, Oct. 1898.)

Paracresol is a patented disinfectant, to which the formula $\text{C}_6\text{H}_4 \begin{Bmatrix} \text{CH}_3(1) \\ \text{OH}(4) \end{Bmatrix}$ is ascribed. It is said to give with water in every proportion a pure, neutral, non-caustic, almost odorless solution, similar to that of phenol, but more active and safer. It is evidently not paracresol, before described, as that has odor and is soluble in water with difficulty.

Solveol and *solutol* are said to be respectively solutions of sodium cresolate in excess of cresol, and of cresol in excess of sodium cresolate. They are affirmed to be about as poisonous as phenol. *Solveol* has been especially praised, it being affirmed to be distinctly more powerful than phenol as a germicide, and in a one-half to five per cent. solution a very valuable antiseptic, especially in major gynecological operations. (See *D. M. W.*, Sept. 1892; *Journ. Méd. de Paris*, 1892.)

Trioresol is a clear, colorless liquid, of a creosote-like odor, a specific gravity of from 1.042 to 1.049, and boiling between 185° and 205° C. (365°–401° F.). It is soluble in cold water to the extent of from 2.2 to 2.5 per cent., and forms a clear solution, thus showing it to be free from neutral oil, naphthalene, etc. It is said to be composed of orthocresol, 35 per cent.; metacresol, 40 per cent.; paracresol, 25 per cent.

The concurrent testimony of Grüber (*Archiv für Hygiene*, 1893), of Walter Reed, U. S. A. (*St. L. M. S. J.*, 1894), of Charteris (*L. L.*, 1894), and other investigators and surgeons, show that tri-cresol is a very active germicide, which is probably three times as powerful as pure phenol. Its 1 per cent. solution even in the presence of albuminous fluids readily destroys pathogenetic bacteria. It may be used for all purposes for which phenol is employed. It is said to affect the skin of the operator much less than does phenol, and to be much less irritating to wounds than either phenol

or bichloride of mercury solutions. It does not act on surgical instruments. For the ordinary purposes of surgery the 1 per cent. solution may be employed. It is probably less toxic than phenol. Charteris, indeed, affirms that it is only one-third as active a poison as is phenol.

Cresol Salicylates. *Cresalols. Cresol Salols.*
 $\text{C}_6\text{H}_4 \begin{Bmatrix} \text{OH} \\ \text{COC}_6\text{H}_4\text{CH}_3 \end{Bmatrix}$. Salicylates may be prepared from ortho-, meta-, or para-cresol by a process similar to that used in the making of salol. They are insoluble in water, slightly soluble in cold alcohol, and are easily crystallized. The *meta-cresol salicylate* is the cresalol generally referred to by that name. It fuses at 74° C. (165.2° F.), and is easily soluble in alcohol and ether. Nencki states that the cresalols decompose in the alimentary canal, and are efficient substitutes for phenyl salicylate, and less poisonous. (*C. R. A. S.*, Feb. 1889.)

Cresol Triiodide. *Meta-cresol Tri-iodide.* (*Losophan.*) $\text{C}_6\text{H}_3(\text{CH}_3)\text{OH}$.—A fine, yellowish powder, with a rather strong, not altogether disagreeable odor; insoluble in water, soluble in alcohol, ether, and chloroform, exceedingly so in oil. Merck (*Jahresbericht*, 1892, 77) describes it as obtained in colorless needles, fusing at 121.5° C. (251° F.). It contains 78.39 per cent. of iodine. A specimen prepared by Friedrich Baeyer & Co. was found by Petersen (*M. M. W.*, July, 1891) to yield its iodine with difficulty, passing through the alimentary canal almost without absorption; applied to the mucous membrane of the nose in *acute inflammation*, it was found to act very well in checking secretion and lessening inflammatory action.

Cresotinic Acid.—*Cresotic acid, homosalicylic acid, oxytoluic acid*, $\text{C}_6\text{H}_3 \begin{Bmatrix} \text{CH}_3 \\ \text{OH} \\ \text{COOH} \end{Bmatrix}$, may exist as ortho, meta, or para modification, and is the homologue of salicylic acid, bearing the same relation to cresol that salicylic acid does to phenol. The cresotic acids may be made artificially from the cresols by a reaction analogous to that used in making salicylic acid.

Only the para compound is used in medicine. It crystallizes in white needles, melting at 151° C. (303.8° F.). As long ago as 1876 *sodium cresotate* was proposed as an antipyretic, but the commercial drug furnished was proved to be a mixture of varying composition, and has been replaced by the pure sodium paracresotate, a white, finely crystallized powder, having a somewhat bitter taste, forming a permanent solution in twenty-four parts of hot water. It is made as stated by the Kolbe process of heating the sodium paracresol with carbon dioxide under pressure. Charteris (*B. M. J.*, March, 1891) found that ortho- and para-cresotic acids act upon rabbits as poisons, the lethal dose being less than half a grain (0.032 Gm.) of the ortho, and one grain (0.065 Gm.) of the para, acid per pound. According to the experiments of Demme (*W. M. Bl.*, Feb. 1870), sixty grains (3.9 Gm.) of the sodium paracresotate may be taken by man without producing very distinct symptoms, except an antipyretic action in cases of fever. The same authority used the drug with asserted good results in *acute articular rheumatism*. In some of the cases marked collapse occurred, in others there was erythematous eruption.

Cruvin. *Quinoline-bismuth sulphocyanide.* ($\text{C}_9\text{H}_7\text{HSCN}$)₂Bi(SCN)₃.—*Quinoline-bismuth rhoda-*

nate, a reddish-yellow powder with weak odor of quinoline, insoluble in water, alcohol, and ether. Crurin of the markets is a preparation containing 25 per cent. of active ingredients with starch. According to the researches of Müller it is bacteriologically active, and it has been especially recommended in the treatment of ulcers of the leg, by dusting them at intervals in full strength or diluted, *pro re nata*. It has also been highly recommended by E. Jacobi in *gonorrhœa*, according to the following formula: Rub fifteen grains (1.0 Gm.) of crurin with seventy-five minims (4.6 Cc.) each of distilled water and glycerin and gradually add sufficient distilled water to make six and one-half troyounces (201.5 Gm.).

Cryptocarya. *Cryptocarya australis*, Benth. (Fam. Lauracæ).—From the bark of this Queensland tree, T. L. Bancroft (*Austral. Journ. Pharm.*, March, 1887) has separated an alkaloid which is said to be a powerful respiratory poison.

Cucurbita. *Cucurbita Citrullus*, L. (*Citrullus vulgaris*, Schrad. *Citrullus Citrullus* (L.), Karst.) *Watermelon*.—The seeds of the watermelon are employed, to a considerable extent, as a domestic remedy in *strangury* and other affections of the urinary passages. They have properties similar to those of the seeds of the other Cucurbitacæ, of which four different kinds were formerly official under the name of the *greater cold seeds*,—viz., those of *Cucurbita Pepo*, L., or *pumpkin*, of *Lagenaria vulgaris*, Ser. (L. *Lagenaria* (L.), Cockerell; *Cucurbita Lagenaria*, L.), or *gourd*, of *Cucumis Melo*, L., or *muskmelon*, and *Cucumis sativus*, L., or *cucumber*. These, when bruised and rubbed up with water, form an emulsion, which was formerly thought to possess considerable virtue, and was much used in *catarrhal affections and disorders of the bowels and urinary passages*. Watermelon seeds are also esteemed by some as a diuretic. The infusion of two ounces of the bruised seeds to a pint may be taken *ad libitum*. In the form of *Arboosnyi miód*, or *watermelon honey*, or as a freshly expressed juice, the Russian peasants are said to employ watermelon in the treatment of *dropsy, urino-genital affections, chronic hepatic congestion, and chronic intestinal catarrh*. Manassein (*Vrach*, Nov. 1881), found that the melon honey acts upon the lower animals as a very powerful diuretic, and causes when in sufficient dose fall of the arterial pressure, rapid pulse, and death from cardiac paralysis.

The pulp of the root of *Lagenaria vulgaris*, or *gourd*, is said by Chapin to be a powerful and even drastic purgative, and to be used by the natives of the Sandwich Islands successfully in the treatment of *dropsy*. (See *N. Y. Journ. of Med.*, 1855, 203.)

Culilawan. *Cortex Culilaban*.—An aromatic bark, produced by *Cinnamomum Culilawan*, Blume (*Laurus Culilaban*, L.), (Fam. Lauracæ), a tree of considerable size, growing in the Molucca Islands, Cochin-China, and other parts of the East. It is usually in flat or slightly rolled pieces, several inches long, an inch or more in breadth, and one or two lines thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The epidermis is for the most part removed, but when present is of a light brownish-gray color, soft to the touch, and somewhat spongy. The color of the bark itself is a dull, dark, cinnamon brown, the odor highly fragrant, the taste agreeably aromatic, and not unlike that of cloves. The active constituent is a volatile oil, smelling like a mix-

ture of the oils of cajuput and cloves. Culilawan has the medicinal properties of the aromatics, but is rarely used. (See *Cortex Caryophyllata*.)

Cumin. *Cuminum*, Lond. *Cuminum*, Ed. *Cumin*, Fr. *Kreuzkümmel*, *Mutterkümmel*, *Römischer (langer, scharfer) Kümmel*, G.—The so-called cumin seeds are the fruit of the *Cuminum Cuminum*, L., an annual umbelliferous plant, which is a native of Egypt, but is cultivated for its fruit in Sicily, Malta, and other parts of Europe.

The cumin fruits (*seeds*) are elliptical, flat on one side, convex, furrowed, and rough on the other, about one-sixth of an inch in length, and of a light brown color. Each has seven longitudinal ridges. Two fruits are sometimes seen united. Their odor is peculiar, strong, and heavy; their taste warm, bitterish, aromatic, and disagreeable. They contain much essential oil, which is lighter than water, yellowish, and has the sensible properties of the seeds. It consists of three distinct oils, one a hydrocarbon, *cymene*, $C_{10}H_{14}$, recognized now as *isopropyl-p-methyl-benzene*, another *cuminol*, $C_{10}H_{12}O$, which may be regarded as *cumin aldehyde*, $C_{10}H_{11}OH$, and the third a terpene, $C_{10}H_{16}$. Dumas, a long time since, obtained a cymene identical with that of oil of cumin seeds, by dehydrating camphor, and Paternò prepared it in a similar way from oil of turpentine. (*J. P. C.*, 4e sér., xx, 409.) In his discovery Paternò seems, however, to have been preceded by several chemists, C. R. A. Wright apparently having the priority. (*A. J. P.*, xlvii, 117; see especially *A. J. P.*, xlv, 452.) Cumin aldehyde has also, together with cymene, been obtained from the seeds of *Cicuta virosa*, L. (Trapp, *Ann. Ch. Ph.*, cviii, 386.) In medicinal properties cumin seeds resemble the other aromatic umbelliferous fruits. Dose, fifteen to thirty grains (1-2 Gm.).

Cumol. *Pseudocumol*. $C_6H_5(CH_3)_3$ (1 : 3 : 4). An oily fluid derived from coal tar, boiling at 168° to 178° C. (334.4° - 352.4° F.). Cumol has been especially recommended by Krönig (*Centralbl. f. Gyn.*, 1894) for the purpose of sterilizing catgut, which is placed in the cumol and slowly heated up to 160° C. (320° F.). After two hours it is removed and freed from the adhering cumol by petroleum benzine.

Cunila. *Cunila origanoides* (L.), Britt. *O. Mariana*, L. *American Dittany*. *Sweet Horse-mint*. *Stonemint*.—A small indigenous perennial herb, growing on dry, shady hills, from New England to Georgia, and flowering in June and July. The whole herb has a warm pungent taste and a fragrant odor, dependent on an essential oil. This, according to Philip Milleman of Chicago, is of reddish-amber color, becoming light yellow by exposure to light, of a delicate, fragrant odor, very similar to that of oil of monarda, of a warm, pungent taste, and of the sp. gr. 0.920. It is readily soluble in alcohol, ether, and chloroform. On spontaneous evaporation, it leaves a small crystalline residue. Iodine decomposes it, producing white vapors; by sulphuric acid it is reddened and decomposed, by nitric acid resinified, and by hydrochloric acid decolorized, though its color returns on exposure. It is slightly rubefacient; in the dose of five or ten minims (0.3-0.6 Cc.) it is carminative, and of from fifteen to twenty minims (0.9-1.3 Cc.) diaphoretic. The same author found in the dried herb tannic acid, a trace of glucose, gum, bitter extractive, resin, and salts of potassium, calcium, magnesium, and iron. (*A. J. P.*, Nov. 1866, 495.) American dittany is a gently stimulant aromatic, analogous to mints.

Cuprargol.—Cuprargol is a dull, grayish-white powder, which is slowly soluble in water, and has been used as an astringent in ophthalmology in 20 per cent. solutions.

Curcuma. U. S. 1870. *Turmeric. Curcuma longa*, L., *Amomum Curcuma*, Jacq., includes *C. rotunda*, L. (Fam. Marantaceæ.)—The rhizome of this plant is perennial, tuberous palmate, and internally of a deep yellow or orange color. The plant is a native of the East Indies and Cochin-China, and is cultivated in various parts of Southern Asia, particularly in China, Bengal, and Java, whence the root is exported. The best is said to come from China.

The dried root (*Safran des Indes, Souchet des Indes*, Fr.; *Kurkuma, Gelbwurzel*, G.; *Curcuma*, It., Sp.; *Zirsood*, Arab.; *Huldie*, Hindoo) is in cylindrical or oblong pieces (*Curcuma longa*), about as thick but not as long as the finger, tuberculated, somewhat contorted, externally yellowish brown or greenish yellow, internally deep orange yellow, hard, compact, breaking with a fracture like that of wax, and yielding a yellow or orange-yellow powder. Another variety (*Curcuma rotunda*), comparatively rare, is round or oval, about the size of a pigeon's egg, and marked externally with numerous annular wrinkles. Sometimes it comes cut into two transverse segments. The two varieties have a close resemblance in sensible properties, and are thought to be derived from the same plant, though formerly ascribed to different species. The odor of turmeric is peculiar; the taste warm, bitterish, and feebly aromatic. It tinges the saliva yellow. Analyzed by Pelletier and Vogel, it was found to contain lignin, starch, a peculiar yellow coloring matter called *curcumin*, a brown coloring matter, gum, an odorous and very acrid volatile oil, and a small quantity of calcium chloride. Curcumin was obtained, mixed with a little volatile oil (about 1 per cent.), by digesting the alcoholic extract of turmeric in ether, and evaporating the ethereal tincture. It has been obtained, by F. A. Daube, in deep yellow crystals, of a diamond lustre, by a process which may be found in the *A. J. P.* (1871, 308). C. L. Jackson and Menke have submitted turmeric root to a thorough examination, and give the following results: The turmeric oil was first removed from the ground root by treatment with ligroine, then the curcumin mixed with a large quantity of resin is extracted with ether, and finally purified by crystallization from alcohol. The oil extracted by ligroine was dark yellow, and amounted to 11 per cent. of the root. The purified curcumin amounted to 0.3 per cent., and melted at 178° C. (352.4° F.). Analyses of the pure curcumin, of several of its salts, and of derivatives, show its formula to be $C_{14}H_{14}O_4$. (*Am. Chem. J.*, iv. 77.) It is brown in mass, but yellow in the state of powder, without odor or taste, insoluble in benzin, scarcely soluble in water, but very soluble in alcohol, ether, and the oils. It is a diatomic monobasic acid. When treated with weak oxidizing agents it yields vanillin. The alkalis rapidly change its color to a reddish brown, and paper tinged with tincture of turmeric is employed as a test of their presence. The paper is rendered brown also by boric acid, which it thus serves to detect. When treated with a mixture of sulphuric and boric acids it yields a product called *rosocyanin*, because it dissolves in alcohol with a fine red color, and is turned blue by alkalis. Its alcoholic solution produces colored precipitates with lead acetate,

silver nitrate, and other salts. Turmeric is used for dyeing yellow, but the color is not permanent. James Cook has found in turmeric an alkaloid, which forms crystallizable salts with sulphuric and nitric acids, and, separated from these acids by ammonia, yields a semi-crystalline precipitate. He observed also indications of a second base. (*P. J.*, Nov. 1870.) Ivanow Gajewsky also states that there is an alkaloid in the root. (*Pharmacographia*, 641.)

This root is a stimulant aromatic, bearing some resemblance to ginger in its operation, and is much used in India as a condiment. It is a constant ingredient in the curries so generally employed in the East. In former times it had some reputation in Europe as a remedy in jaundice, but its medicinal action was purely imaginary, based on the old doctrine of signatures, and at present it is employed only to impart color to ointments and other preparations.

Turmeric, when used as an adulterant, may be detected by means of a mixture of boric and sulphuric acids, but according to A. E. Bell, a much better test is afforded by the use of the reagent made by dissolving 1 gramme of diphenylamine in 20 Cc. of 90 per cent. alcohol, carefully adding 25 Cc. of pure sulphuric acid. To a little of the suspected powder, placed on a slide, a drop of the reagent is added with a glass rod. Spots of a fine purple color immediately develop, which may be readily recognized with the microscope.

Turmeric paper, used as a test, is prepared by tingeing white unsized paper with a tincture or decoction of turmeric. The tincture may be made with one part of turmeric to six parts of proof spirit; the decoction, with one part of the root to ten or twelve of water. The access of acid or alkaline vapors should be carefully avoided.

Curry Leaves. *Currie.*—The leaves of the *Murraya (Bergera) Kœnigii*, Spreng. (Fam. Aurantiaceæ), a tree of India, are very largely used in that country as an aromatic, stomachic stimulant; when powdered and mixed with spices and other substances it forms *curry powder*, which is much used for seasoning food, rice, cooked dishes, etc.; it is also employed in *dyspepsia*, *diarrhœa*, and even *dysentery*. According to J. G. Prebble (*Pharmacographia Indica*, vol. i.), curry leaves yield to distillation a small quantity of volatile oil, and also contain a greenish-black resin, and a glucoside, *kœnigin*. The clear oil extracted from the seeds is known as *simabolee* oil.

Cuttlefish Bone. *Os Sepiæ, Os de Sèche (Seiche)*, Fr. *Sepie, Weisses Fischbein*, G.—This is a calcareous body, situated underneath the skin, in the back of the *Sepia officinalis*, L., or *cuttlefish*, of European seas. It is oblong-oval, from five to ten inches long, and from one and a half to three inches broad, somewhat convex on both sides, with thin edges, of a rather firm consistence upon the upper surface, very friable beneath, and composed of numerous layers, loosely connected, so as to give to the mass a porous consistence. It is lighter than water, of a white color, a feeble sea odor, and a saline taste. It contains, according to John, from 80 to 85 per cent. of calcium carbonate, besides animal matter, a little common salt, and traces of magnesia. Its fine powder may be given as an antacid, and it is sometimes used as an ingredient of tooth-powders. Small pieces of it are often put into bird cages that the birds may rub their bills against them, and the powder is employed for

polishing. Another product of the cuttlefish is a blackish-brown liquor, secreted by a small gland in an oval pouch, communicating externally near the rectum by a long excretory duct, through which the animal is said to have the power of ejecting it at will. This, when taken from the fish, is dried, and used in making the water-colors *sepia* and *India ink*.

Cyclamen. *Cyclamen europæum*, L. *Pain de Porceau*, *Arthanite*, Fr. *Erdscheibe*, *Erdbrod*, *Schweinbrod*, G. *Sowbread*.—This is an herbaceous, perennial, stemless plant, of the south of Europe. The root is globular, with many branched fibres, almost black without, and white within, inodorous, and, when fresh, of a bitter, acrid, burning taste. By drying it loses much of its acrimony, and is said to be rendered edible by roasting. Hogs are said to root it up from the ground and to eat it with impunity, and hence its common French name. The root is a drastic cathartic, and is used to cause abortion, but has in such cases produced fatal gastro-enteritis. Its active principle appears to be *arthanitin* of Saladin, the *cyclamin* of S. De Luca. This is a poisonous glucoside, which, when boiled with diluted acids, splits into *cyclamiretin*, $C_{15}H_{25}O_2$, and glucose. It is white, amorphous, inodorous, and, when held a short time in the mouth, intensely acrid, extending its action even to the throat. With cold water it swells and becomes gelatinous, but is readily dissolved, and forms a solution which froths like soap and water, and is coagulated by a heat of about 65.5° C. (150° F.). Alcohol dissolves it with difficulty when cold, but freely when hot; it is soluble in glycerin with the aid of heat; and is insoluble in ether, chloroform, carbon disulphide, and the essential oils. Its formula, according to an analysis by Klinger, is $C_{20}H_{34}O_{10}$, although Kobert (*Chem. Cb.*, 1893, i. 32) makes it one of the class of saponins, and gives it the formula $C_{20}H_{32}O_{10}$, which is the same as that of sarsaparilaponin and smilacin. T. W. C. Martius recommends the following method of preparing it. The tubers, collected in the autumn, dried and powdered, are mixed with animal charcoal, and exhausted at a boiling heat by alcohol of 0.825; the tincture is filtered, concentrated, and set aside for six or eight weeks, when the cyclamin is deposited. This should be washed on a filter with alcohol till it passes colorless, and if the filtrate be concentrated, and set aside, it will deposit a further quantity in a few weeks. The whole is then mixed with animal charcoal and treated with boiling alcohol, which will slowly deposit the pure cyclamin on cooling. Dose, of powdered root is said to be from twenty to forty grains (1.3–2.6 Gm.).

Cydonium. U. S. 1880. *Quince Seed*. *Semen Cydoniæ*. *Semences (Pépins) de Coing*, Fr. *Quittenkerne*, *Quittensamen*, G. *Semi di Cotogno*, It. *Simiente de Membrillo*, Sp.—The *Pyrus Cydonia*, L. (*Cydonia vulgaris*, Pers.), or common quince tree, is characterized as a species by its downy, deciduous leaves. It is supposed to be a native of Crete, but grows wild in Austria, on the banks of the Danube. The fruit is yellow, downy, of an agreeable odor, and a rough, astringent, acidulous taste, and in each of its five cells contains from eight to fourteen seeds. Though not eaten raw, it forms a very pleasant confection, and a syrup prepared from it may be used as a grateful addition to drinks in sickness, especially in looseness of the bowels, which it is supposed to restrain by its astringency. The seeds, which were formerly official, are ovate, angled, reddish-brown exter-

nally, white within, inodorous, and nearly insipid, being slightly bitter when long chewed. Their coriaceous envelope abounds in mucilage, which is extracted by boiling water. "About a quarter of an inch (6 Mm.) long, oval or oblong, triangularly compressed, brown, covered with a whitish, mucilaginous epithelium, causing the seeds of each cell to adhere. With water the seeds swell up, and form a mucilaginous mass. The unbroken seeds have an insipid taste." U. S. 1880. Two drachms of the seeds will render a pint of water thick and ropy. (A. J. P., 1876, 35.) It has been proposed to evaporate the decoction to dryness, and powder the residue. Three grains of this powder form a sufficiently consistent mucilage with an ounce of water. According to Garot, one part communicates to a thousand parts of water a semi-syrupy consistence. (J. P. C., 3e sér., iii. 298.) Pereira considers the mucilage as peculiar, and proposes to call it *cydonin*. It differs from arabin in not yielding a precipitate with potassium silicate, and from bassorin and cerasin in being soluble in water both hot and cold. Tollens and Kirchner (*Ann. Ch. Phys.*, clxxv. 205–226) assign to it the formula $C_{12}H_{22}O_{14}$, regarding it as a compound of gum, $C_{12}H_{20}O_{10}$, and cellulose, $C_6H_{10}O_5$, less one molecule of water. Quince mucilage is very bland, and may be used for the same purposes as other mucilaginous liquids. The U. S. P. 1880 gave the following formula for its preparation. "Cydonium, two parts [or thirty-six grains]; Distilled Water, one hundred parts [or four fluidounces]. Macerate the Cydonium for half an hour, in a covered vessel, with Distilled Water, frequently agitating. Then drain the liquid through muslin, without pressure. This preparation should be freshly made, when required for use." U. S. 1880.

Cynara. *Cynara Cardunculus*, L. (*C. Scolymus*, L.) *Artichoke*.—This is a composite plant, indigenous in the south of Europe, and cultivated as a culinary vegetable. The receptacle and the lower portion of the fleshy leaflets of the flower-heads are eaten. When young, the heads are cut up raw and eaten as salad; when older, they are boiled, and dressed variously. The flowers are said to curdle milk, and the plant to yield a good yellow dye. The leaves and their expressed juice are very bitter, and have been thought to be actively diuretic. Artichoke leaves have been used in *dropsies* and *rheumatic affections*.

Cynoglossum. *Cynoglossum officinale*, L. *Hound's-tongue*, *Langue de Chien*, Fr. *Hundszunge*, G.—A biennial plant of the fam. Boraginaceæ; common both in Europe and in this country. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odor, resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Although hound's-tongue has been believed by some to be nearly inert, there can be little doubt that it is a dangerous poison. The experiments of Diedtlin (*M. S. Rep.*, 1868) many years ago demonstrated that the extract paralyzes motor nerves in vertebrate animals, and K. Greimer has found in it a poisonous alkaloid, *cynoglossine*, which acts upon the animal organism similarly to curare; also a toxic glucoside, *consolidin*, and a notable amount of *choline* (P. J., vol. lxx.). *Consolidin*, a derivative of *consolidin*, like *consolidin*, paralyzes the central nervous system. *Cynoglossum* has been used as a demulcent and

sedative in coughs, catarrh, spitting of blood, dysentery, and diarrhoea. The *pilule de cynoglossa* owe their properties chiefly to opium.

Cytisus. *Cytisus Laburnum*, L. *Laburnum vulgare*, Grisebach. *L. anagyroides*, Medic. (Fam. Leguminosæ.)—*Laburnum* is a small tree, indigenous in the higher mountains of Europe and cultivated throughout the civilized world, for its flowers, which appear early in the spring in rich pendant yellow clusters. All parts of the plants are probably poisonous. In fifty-eight boys poisoned simultaneously by the roots, the symptoms were intense sleepiness, vomiting, convulsive movements, coma, slight frothing at the mouth, and unequally dilated pupils. (*M. T. G.*, vol. ii. 875.) In some cases the diarrhoea has been severe. The convulsions have at times been markedly tetanic; wide-spread anaesthesia has been noted, and also excessive mydriasis, with loss of the pupillary reflex, elevation of temperature, delirium, and cyanosis. After death there have been found erosion of the colonic mucous membrane, extreme hyperæmia of the brain, and nephritis. (*D. M. W.*, xxi. 1895.) For cases, see also previous editions of the *U. S. D.*; *Arbeiten Pharm. Instit. Dorpat*, ii. 1888; *Le Mouvement Méd.*, 1875, No. 28; *Dublin Q. J.*, 1863, 248; *M. T. G.*, Sept. 1862; *L. L.*, Aug. 1870. Chevallier and Lassaigne discovered in the seeds of *laburnum* a white, amorphous, deliquescent, non-nitrogenous substance, of a bitter nauseous taste, soluble in water and weak alcohol, and insoluble in ether. In small doses it produced, in animals, vomiting, convulsions, and death. (Mérat and De Lens.) Husemann and Marmé isolated in 1864 an alkaloid, *cytisine*, a white, crystalline solid, of a bitter, somewhat caustic taste, soluble in water and alcohol, but scarcely at all soluble in ether, chloroform, benzene, or carbon disulphide. A second alkaloid, *laburnine*, was also announced by them. (*Chem. News*, July 16, 1869, 36.) Partheil (*A. Pharm.*, 1892, 448) has since studied *cytisine*, and gives it the formula $C_{11}H_{14}N_2O$, which has been adopted by other authorities. He considers it to be identical with the *ulevine* of the *Ulex europæus*, L. (Fam. Leguminosæ). Ferric chloride colors *cytisine* and its salts blood-red, which color, however, disappears on diluting with water or on addition of hydrogen dioxide. If after the addition of this latter reagent the mixture is heated gently in the water bath an intense blue color is developed. When *cytisine* is distilled with soda lime, pyrrol is obtained, besides a base, $C_9H_{13}N$, which is possibly a hydroquinoline. A. Rannerda purified crude *cytisine*, obtained from the seeds of *Cytisus Laburnum*, L., by the well known shaking out process with chloroform, by distilling it in a partial vacuum. Under a pressure of 2 Mm. and a temperature of 228° C., the alkaloid distils over as a colorless liquid and congeals in the receiver in the form of fine crystalline needles. It separates from absolute alcohol in the form of small transparent rhombic crystals, which have the sp. gr. 1.0046. (*Ap. Ztg.*, July, 1900, 486.) *Cytisine* is stated to be found also in *arnica* flowers.

According to the researches of P. C. Plugge (*A. Pharm.*, 1895), *cytisine* is a very widely distributed alkaloid. He has found it in eight species of the genus *Cytisus*, two of the genus *Genista*, two of the genus *Sophora*, two of the genus *Baptisia*, and in other plants. He asserts that *ulevine* of Gerrard, from *Ulex europæus*, L.; *sophorine* of H. C. Wood, from *Sophora secundiflora*

(Cav.), DC. (*S. speciosa*, Benth.), and *baptisine* of von Schroeder, from *Baptisia tinctoria*, R. Br., are identical with *cytisine*. Plugge also believes that the alkaloid of *Euchestra Horsfieldii*, Benn. (Fam. Leguminosæ), a Javanese pea, whose seeds are used as a contra-poison by the natives, is identical with *cytisine*. Kobert and Radziwillowicz (*loc. cit.*) find that in the lower animals the symptoms of poisoning by *cytisine* resemble somewhat those of strychnine poisoning, but are attended by much vomiting of centric origin; that the alkaloid depresses even in the living organism the ozonizing properties of the red corpuscles; that it first excites and afterwards paralyzes the centre of respiration, and probably in this way causes death; that it also powerfully stimulates the vasomotor centres, producing a marked elevation of blood pressure which is independent of the heart and is followed, if the dose has been large enough, by a gradual fall of pressure, due to paralysis of the vasomotor centres. The motor side of the spinal cord is also strongly excited by small, and finally paralyzed by large, doses. The peripheral ends of the motor nerves are paralyzed in a curare-like method. The alkaloid also seems to have a distinct action upon the uterus, and has frequently produced abortion. Therapeutic trials were made with the alkaloid in hypodermic doses of one-twelfth grain (0.005 Gm.), or by the mouth in from one- to three-minim (0.06–0.2 Cc.) doses of the 1 per cent. solution, in conditions of depression, without much effect. Gray (*J. P. C.*, 1862) found *laburnum* to produce in man narcotic effects, and commends it in vomiting, bronchitis, whooping cough, and asthma.

Damiana.—Under this name have been sold in the American market as aphrodisiacs several distinct Mexican drugs. According to Wellcome, there were on the market in 1875 (*A. J. P.*, xlvii.) at least three of these, each claiming to be genuine.

Of these various drugs, one had a smooth, dark green, broadly lanceolate, dentate leaf, usually having six teeth on each side, heavy midrib, and ribs extending to the point of the teeth, from two to five lines in width and from six to twelve in length; the stem was red and woody, and the leaves gave a minty flavor when chewed. The second variety had a light green, obovate, deeply toothed leaf, having three and occasionally four teeth on each side, with a heavy midrib, and branching ribs extending to the edge. The surface was rough, and both sides were covered with short hairs. It was from two to five lines in width and five to eight in length. The stem was very woody, and near the apex it was quite hairy; on chewing it yielded a sage-like flavor. In the third variety the leaf was light green, lanceolate, having three teeth on each side, which terminated in hard, sharp points; it had a distinct midrib, and was rather indistinctly veined; was from one and a half to three lines in width and four to ten in length. It was quite thick and had a rough surface, with occasional black dots. To the naked eye the leaf appeared to be covered with shining scales, which, under the glass, appeared as minute resin-like globules. This was the only specimen accompanied by flowers. They were compound, with yellow florets and white pappus; the stem was woody, with green epidermis, and covered with resinous secretion. In 1882 there were two *damianas* in the Philadelphia market. One was chiefly composed of pieces of stems and branches, but

contained enough of floral heads and leaves to show that it was the third variety of Wellcome, and was the product of one of the Compositæ, *Bigelovia veneta*, Gray (*Aplopappus discoideus*, DC.). (*M. S. Rep.*, xxxiv. 180.) The second variety was that considered by the introducers as *genuine damiana*. It was the leaves and terminal twigs of a *Turnera* (Fam. *Turneraceæ*), supposed by some to be a new species, *T. aphrodisiaca*, L. F. Ward, now recognized as identical with *T. diffusa*, Willd., and probably only a variety of *T. microphylla*, DC. It is this drug which constitutes the damiana of commerce. The leaves are from three to eight lines long, one to three lines broad, obovate to lanceolate, eight to ten sharp-toothed, smooth or with a few hairs on ribs below, midrib marked with, in some cases, strong, straight veins running to the edge between the teeth; in other cases veins branched and sending a final vein into the tooth; stems fine, woody, reddish, ends of branches hairy. F. W. Rantzer (*A. J. P.*, 1887, 69) obtained from the leaves of this species about one-half per cent. of an amber-colored volatile oil, with a heavy aromatic odor, and a warm, camphoraceous, and bitter taste; also tannin, two tasteless resins, and extractive.

The published reports as to the value of the drug vary greatly, some having had great success with it in *sexual atony*, most others finding it useless; it is probably nothing more than a feeble tonic. *Dose*, an ounce (31 Gm.) of the leaves, either in the form of infusion or fluidextract, may be given daily.

Danais. *Danais fragrans*, Gaertn. f. (Fam. *Rubiaceæ*).—In this Madagascar plant, the root of which is said to be tonic and antiperiodic, Heckel and Schlagdenhauffen found a glucoside, *danain*. (*A. J. P.*, 1886.)

Daphnandra.—The bark of several species of Australian trees belonging to the genus *Daphnandra* (Fam. *Monimiaceæ*) is asserted to be rich in poisonous alkaloid. (*P. J.*, Oct. 1887.) Bancroft states that the active alkaloid is soluble in water, and to some extent is antagonistic to strychnine.

Delphinium.—It is probable that most if not all of the species of this genus of *Ranunculaceæ* are actively poisonous. Thomas C. Hopkins of Baltimore, found in the seeds of *D. consolida*, L., or *Larkspur* (*Lark's claw*, *Knight's spur*), *delphinine* ($C_{24}H_{35}NO_2$), volatile oil, fixed oil, gum, resin, chlorophyll, gallic acid, and salts of potassium, calcium, and iron. (*A. J. P.*, xi.) Rochebrune (*Toxicol. Africaine*, i.) has separated alkaloids believed by him to be identical with *delphinine* from *D. peregrinum*, L., and *D. mauritanicum*, Coss. From the expressed juice of the larkspur *aconitic acid* was obtained by W. Wicke. (*J. P. C.*, 1854.) Moreover, the seeds of the indigenous *D. urceolatum*, Jacq. (*D. exaltatum*, Ait.), are stated to have a physiological action similar to that of the larkspur. The common larkspur (*D. consolida*) is a showy annual, which has been introduced from Europe into the United States, where it has become naturalized, growing in the woods and fields, and flowering in June and July. The flowers are bitter and acrid. In large doses the seeds produce violent vomiting and purging, and are said to be diuretic. They were formerly in the Secondary List of the U. S. Pharmacopœia, and a tincture (1 fl. oz. to 1 pint diluted alcohol) has been used in spasmodic *asthma* and *dropsy*. *Dose*, ten minims (0.6 Cc.), gradually increased. Brett has found that *D.*

peregrinum, L., when growing, is very effective in the destruction of grasshoppers. (*P. J.*, vol. xxi. 1891. See *Staphisagria* in PART I.)

Dextroform is a combination of formaldehyde and dextrin, soluble in water and glycerin, but insoluble in alcohol, ether or chloroform; it occurs as a white almost odorless and tasteless powder; it should be used with caution. It affords, according to Bongartz, in from 10 to 20 per cent. solution, a useful injection in *gonorrhœa* and other toxic diseases, or is used for irrigation in half strength.

Dialiopsus. *Dialiopsus africana*.—In the seeds of this plant Beitter has found a poisonous glucoside belonging to the saponins. (*B. P. G.*, 1902.)

Diamine (*Hydrazin*), $\begin{matrix} H_2N \\ H_2N \end{matrix}$, is a strong base crystallizing in white crystals at 1.4° C. (34.5° F.) and boiling at 113° C. (235.4° F.); it forms salts with the common acids. The free base mixes with water in all proportions and has a strong alkaline character and powerful reducing action. This substance has been proved by Julius Pohl to be actively poisonous. (*A. E. P. P.*, xli. 1898.)

Dianthus. *Dianthus Caryophyllus*. *Clove Pink*. (Fam. *Caryophyllaceæ*).—Of the ordinary garden pink those specimens should be selected for medicinal use which have the deepest red color and the most aromatic odor. The petals should not be collected until the flower is fully blown, and should be employed in the recent state. They have a fragrant odor, thought to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation. In Europe they are employed to impart color and flavor to a *symp*, used as a vehicle. The Edinburgh Pharmacopœia directed this to be made by macerating one part of the flowers, without their claws, in four parts of boiling water for twelve hours, then filtering, and adding seven parts of sugar.

Diaphthol. *Quinaseptol*. *Ortho-oxyquinoline-metasulphonic Acid*. $C_9H_7N.OH.SO_3H$.—Occurs in yellowish-white crystals fusing at 295° C. (563° F.), slowly soluble in cold water. It is an antiferment said to be without toxicity and introduced by Guignard as a urinary disinfectant to replace salol.

Diastin.—A form of diastase introduced for use in certain forms of amylaceous dyspepsia. It is given in the dose of five grains (0.32 Gm.).

Diathesin. *Ortho-oxybenzylalcohol*. *Salicyl alcohol*. $C_6H_4(OH)CH_2OH$.—This phenol-alcohol may be prepared from salicin by the action of dilute acids or emulsin. It forms colorless crystals melting at 86° C. (186.8° F.) and soluble in fifteen parts of water at 22° C. (71.6° F.). It gives a blue color with ferric chloride. This substance has been proposed by L. Lederer (*M. M. W.*, No. 7, 1899) as an antirheumatic and antiseptic. It exists in salicin in combination with glucose, and it is believed by Lederer that the activity of salicin depends not upon the conversion of the ortho-oxybenzylalcohol into salicylic acid, but upon the direct influence of the diathesin. In *rheumatism* it may be given in seven-grain (0.45 Gm.) doses every two hours.

Dichloral Antipyrine. $C_{11}H_{12}N_2O.[CCl_3CH(OH)]_2$.—Made by triturating 94 parts of antipyrine with 165.5 parts of hydrated chloral and crystallizing from hot water. It differs from hypnal in containing one molecule more of the hydrated chloral. Its uses and dose are the same as hypnal, viz., from five to twenty grains (0.32 to 1.3 Gm.), as an analgesic and hypnotic.

Didymium is now recognized generally as a mixture of *neodymium* and *praseodymium*, the salts of the former being in general rose-colored while those of the latter are of a greenish-yellow. The by-products obtained in the manufacture of gas mantles and certain other chemical manufactures have been utilized in making the salts.

Didymium Chloride, Didymii Chloridum.—This salt has been used in the form of a rose-red, odorless and non-irritant solution containing 25 per cent. to 30 per cent. of the salts. It has been affirmed that the chloride is superior to phenol as a germicide, but the experiments of I. Schmidt and of Pfücker (*M. R.*, 1898, 1900) show that it is much inferior, a 5 per cent. solution being required to destroy ordinary germs.

Didymium nitrate, Didymii Nitras, $\text{Di}_2(\text{NO}_3)_6 \cdot 12\text{H}_2\text{O}$, occurs in rose-colored crystals soluble in water and alcohol. Antiseptic in solution of the strength of 1 in 2000. (*Cb. B.*, xxi.)

Didymium Salicylate, Dymol.—A very fine white powder free from odor. It has been specially recommended by Kopp, Roth, and others as an innocuous, non-irritant, desiccant, and antiseptic dusting powder in various skin diseases, especially in weeping *eczema*, and also *hidrosis*, and *burns* of the first and second degree. In *erysipelas* and drier forms of skin disease it failed to be of service.

Didymium Sulphate, Didymii Sulphas.—This salt has been marketed in the form of a pale rose-red powder to be used for disinfecting closets, etc.

Diervilla. *Diervilla trifida*, Moench. *D. canadensis*, Muhl. *D. Diervilla* (L.), MacM. *Bush Honeysuckle.*—A low, erect indigenous shrub, growing especially in rocky places throughout the Northern States. The whole plant is supposed to be possessed of diuretic and astringent properties, and is given in infusion by the eclectics in diseases of the urinary passages.

Diethylketone.—*Propione*, $\text{C}_2\text{H}_5\text{CO} \cdot \text{C}_2\text{H}_5$, is obtained by the dry distillation of *calcium propionate* $(\text{C}_3\text{H}_5\text{O}_2)_2\text{Ca}$. A transparent liquid, soluble in twenty-four parts of water, mixing with water, alcohol, and ether, boiling at 101°C .; (213.8°F .); recommended by Albanese and Barabini in 1892, as inducing sleep in animals. It has been used by Giovanni in the treatment of *maniacal* and *hysterical excitement* in doses of from eight to twenty grains (0.5–1.3 Gm.). It should be administered in dilute solution.

Diiodoacetylene, C_2I_2 , is made simultaneously with *tetraiodoethylene*, C_2I_4 , by the action of a solution of iodine in potassium iodide upon calcium carbide. The two are separated by reason of their different solubilities. It occurs in small crystalline needles, insoluble in water but dissolving in oil of sweet almond. It has been found by E. Mebert (*A. E. P. P.*, xli. 1898) to be very actively poisonous. This fact, together with its penetrating odor, makes it improbable that it will be of practical value in medicine.

Diiodoform. *Tetraiodoethylene. Ethylene Periodide.* C_2I_4 .—Obtained by the action of iodine on a solution of acetylene iodide in carbon disulphide. In the form of bright yellow, odorless, needle-like crystals, insoluble in water, only slightly soluble in alcohol but readily soluble in chloroform. It contains 95.5 per cent. of iodine and is recommended in the place of iodoform. It is decomposed by exposure to light.

Diiodosalol. *Phenyl Diiodosalicylate.* $\text{C}_6\text{H}_2\text{I}_2(\text{OH})\text{CO}_2\text{C}_6\text{H}_5$.—Made by the condensation of di-

iodosalicylic acid with phenol. An odorless and tasteless crystalline powder melting at 135°C . (275°F .). Used as an antiseptic in the treatment of *skin diseases*.

Dimethyl Sulphate, $(\text{CH}_3)_2\text{SO}_4$, is a liquid boiling at 188°C . (370.4°F .), soluble in alcohol and ether. This substance has recently come into importance with toxicologists on account of the number of fatal cases of poisoning occurring from it, due to its extended use in chemical factories. It acts locally as a strong caustic and also influences the central nervous system, producing *nystagmus*, *convulsions*, and *respiratory death* during coma. (See S. Weber, *A. E. P. P.*, Bd. xlvii.)

Dinitrocresol. $\text{C}_6\text{H}_2(\text{NO}_2)_2$ $\left\{ \begin{array}{l} \text{CH}_3 \\ \text{OH} \end{array} \right.$.—Commercial *Saffron Substitute* is a mixture of the potassium salts of dinitro-ortho- and para-cresols. It is said to have been sold for saffron in Berlin, with fatal results. (*Ph. Rund.*, Prague, 1887.)

Dionine. *Ethyl-morphine Hydrochloride.*—This substance is a white, somewhat bitter, micro-crystalline powder fusing at 123° to 125°C . (253.4° to 257°F .), soluble in seven parts of water, one and a half parts of alcohol, and twenty parts of syrup; insoluble in ether and chloroform; precipitated from its solutions by most of the alkaloidal reagents. First brought forward by Ludwig Hesse (*Ph. Cb.*, xl.). It has been reported upon by numerous practitioners. It shares the analgesic and hypnotic powers of morphine, but does not produce the nausea, constipation, and other disagreeable after effects of that alkaloid. Upon the respiratory centres it acts even more powerfully than does morphine. It is at the same time an active antihidrotic, so that it is a most valuable remedy in the treatment of advanced *tuberculosis of the respiratory tract*. It has been especially praised as a sedative in cases of *nymphomania*, *masturbation*, and other forms of *sexual excitement* and irritability. It may be employed in *asthma* and all cases in which there is excessive cough, in all forms of pain, including *dysmenorrhoea*, and indeed in any case in which opium has formerly been used, except when it is desired to check secretion in the intestines. It also has the advantage in not lessening the secretion from the lungs. It is, however, less decisive in its action than is morphine, so that in cases of severe pain morphine will bring relief after the failure of dionine. *Dose*, one-fourth to one-half of a grain (0.016 to 0.032 Gm.), in powder, pills, or solution.

As a local remedy a five per cent. solution of dionine has been considerably employed by ophthalmologists. It produces immediate irritation and great swelling of the conjunctiva, followed in a short time by rapid subsidence of the swelling and a condition of analgesia and *anesthesia*. The swelling is produced by the lymphatic inundation, and during the period of subsidence interstitial deposits are likely to be softened and removed. (See H. C. Wood's *Treatise on Therapeutics*.)

Dioscorea. *Dioscorea villosa*, L. *Wild Yam-root. Colic-root. Rheumatism-root.* (Fam. *Dioscoreaceae*).—An indigenous perennial creeper, with long, branching, contorted, ligneous roots. It grows from Ontario to Wisconsin, and south to Florida and Texas. The roots are used by the eclectics, who consider them efficacious in *bilious colic*, and by the Southern negroes in *rheumatism*. W. C. Kaltefleiter found abundant saponin in the roots. (*A. J. P.*, 1888.) A substance, improperly called

dioscorein, obtained by precipitating the tincture with water, is used in the dose of from one to four grains (0.065–0.26 Gm.). *Dose*, of decoction (1 oz. in 1 pint), four to eight fluidounces (120 to 240 Cc.); ten minims to one fluidrachm (0.6–3.75 Cc.) of fluidextract.

Dioscorea hirsuta, Bl., grows in the island of Java, where it is known as *Gadoeng*. In 1894 W. G. Boorsma (*Mededeelingen uit's Lands Plantentuin*, xiii.) separated from it an alkaloid to which he gave the name of *dioscorine*. This alkaloid has been elaborately studied chemically and physiologically by Plugge and Schutte (*A. J. P.*, iv, 1897), who obtained it in crystals having the formula $C_{13}H_{19}NO_2$, and found it to be a convulsant poison, resembling closely in its action picrotoxin, but much more feeble. *Dioscorea bulbifera*, L., grows in the Gaboon country of tropical Africa. Heckel and Schlagdenhaufen found in the tuber a glucoside, together with wax, chlorophyll, saccharose, and resin.

The root of *Dioscorea rhipogonoides*, Oliver, under the names of *Cunao*, *Shu-lang*, *fawa gambier*, is exported in enormous quantities from Indo-China to Southern China for use as a dye-stuff.

Diospyros. *Persimmon.* *Date-plum.* *Fruits de Plaqueminiér de Virginie*, Fr. *Persimmonfrüchte*, *Dattelpflaumen*, G.—The *Diospyros virginiana*, L., or *persimmon* (Fam. Ebenaceæ), is a small indigenous tree. The fruit is a globular berry, dark yellow when ripe, and containing numerous seeds in a soft yellow pulp. The seeds, dried, roasted, and ground, are used in some parts of Georgia as a substitute for coffee. (*M. S. Rep.*, 1873, 437.)

This tree, common in the Middle and Southern States, does not flourish beyond the forty-second degree north. The flowers appear in May or June, but the fruit is not ripe until the middle of autumn. While green, the fruit is excessively astringent, and in this form was formerly included in the U. S. Secondary List; but, when perfectly mature, and after being touched by the frost, it is sweet and palatable. The unripe fruit, according to B. R. Smith of Philadelphia, contains tannic acid, pectin, sugar, malic acid, coloring matter, and lignin. (*A. J. P.*, xviii, 167.) The tannic acid was considered by John E. Bryan not to be of the kind existing in galls and oak bark. (*Ibid.*, xxxii, 215.) Charropin (*Pharmacographia*, 403), however, believes the tannic acid to be identical with that of nutgalls, and finds besides an abundance of pectin, glucose, and a yellow coloring matter insoluble in water, but dissolving freely in ether. Wm. Schleif, Jr. (*A. J. P.*, 1890, 390), extracted from persimmon bark a resinoid principle, in the form of crystalline masses, soft and waxy when freshly crystallized from alcohol or ether, drying to a brownish mass of peculiar odor and slightly astringent taste, soluble in alcohol, ether, chloroform, very slightly in water. Heated to 258° C. (496.4° F.) it darkens considerably, and is decomposed at 262° C. (503.6° F.). The persimmon has been used by Mettauer in *diarrhæa*, *chronic dysentery*, and *uterine hemorrhage*. The dose of the vinous tincture (an ounce of the fresh green fruit to two fluidounces of dilute alcohol) is a fluidrachm (3.75 Cc.) or more for infants, and half a fluidounce (15 Cc.) or more for adults. The bark is astringent and very bitter.

Dioxynaphthalene, $C_{10}H_8O_2$, may exist in several modifications, the best known being the *α*- and *β*-hydronaphthoquinones. They are diatomic

phenols in character. Lépine (*S. M.*, Np. 31, 1887) finds that dioxynaphthalene produces in dogs and guinea pigs violent convulsions, alteration in the color of the blood, due to the formation of methæmoglobin, and blackening of the urine. He asserts that in asthenic persons doses of three grains (0.2 Gm.) a day increase power.

Dippel's Animal Oil. *Oleum Cornu Cervi*. This oil was formerly produced in the process of obtaining ammoniacal products from bone or horn, and is distinguished by the presence of pyridine and quinoline, to which bases its odor is largely due. (See early editions of *U. S. D.*)

Dircæ. *Dircæ palustris*, L. *Leather Wood*. Fam. Thymelacææ.—A shrub growing widely in the Northeastern United States. The berries, which are small, oval, and of an orange color, are said to be narcotic and poisonous. The tough bark, in the fresh state, has a peculiar rather nauseous odor, and an unpleasant acrid taste, and when chewed excites a flow of saliva. It yields its acrimony completely to alcohol, but imperfectly to water even by decoction. Six or eight grains of the fresh bark produce violent vomiting, preceded by a sense of heat in the stomach, and often followed by purging. Applied to the skin it slowly excites redness and ultimately vesicates. It is analogous to mezereon in its medicinal as well as botanical characters.

Dithio-Salicylic Acid. $C_6H_3(OH)COOH.S\backslash$
 $C_6H_3(OH)COOH.S\swarrow$

According to O. Z. (1889, 298) dithio-salicylic acid, a proposed substitute for salicylic acid, is made by heating equal molecules of *sulphur chloride* and *salicylic acid* to from 120° to 150° C. (248°–302° F.), dissolving the light yellow residue in sodium hydroxide, and precipitating the acid, by addition of HCl, as a resinous straw-colored mass, forming, after pulverization, a light yellow powder, easily soluble in alcohol, benzene, and glacial acetic acid. The sodium salt of the acid, *sodium dithio-salicylate*, called also *dithion*, is said by Lindenborn (*Rép. de Pharm.*, Sept. 1889) to be preferable in the treatment of *rheumatism* to salicylic acid, because more energetic and less apt to disturb the digestion. It is asserted that, as an antiseptic, it is fully equal to *sodium salicylate*. *Dose*, three grains (0.2 Gm.), repeated according to circumstances. Ten grains (0.65 Gm.) are said to produce nausea, tinnitus aurium, and sweating.

Doundaké. *Dundaki*, *Quinquina Africaine*. *Kina du Rio Nunez*.—*Sarcocephalus esculentus*, Afzel (Fam. Rubiaceæ), of Africa yields a bark which is said to be an astringent and tonic febrifuge. For a description of the bark and its chemical characteristics, see *P. J.*, vol. xvi, 49. Heckel and Schlagdenhaufen do not believe that doundaké contains an alkaloid, but attribute its power to three distinct principles of a resinous nature, the first of which is of an orange-yellow color and very bitter, soluble in water, alcohol, and potassium hydroxide; the second light yellow in color, soluble in potassium hydroxide but not in water; the third soluble in potassium hydroxide, insoluble in water and in alcohol. (*J. Soc. Chem. Ind.*, 1886, 435.)

Dracontium. *Spathyema fetida* (L.), Raf. *Skunk Cabbage*. *Skunk Weed*. *Polecat Weed*. *Racine de Pothos fétide*, Fr. *Stinkende Drachenzurzel*, G. *Dracontium fetidum*, L. *Iotodes fetidus*, Bigelow.—This plant is abundant in wet places throughout the Northern and Middle United States. All parts of it have a fetid odor, de-

pendent upon an extremely volatile principle, which is rapidly dissipated by heat. The rhizome should be collected in the autumn, or in the early spring.

The rhizome occurs either whole or in transverse slices. When entire, it is cylindrical or in the shape of a truncated cone, two or three inches long by about an inch in thickness, externally dark brown and very rough from the insertion of the radicles, internally white and amylaceous. The rootlets are of various lengths, about as thick as a hen's quill, very much flattened and wrinkled, white within, and covered by a yellowish or reddish-brown epidermis, considerably lighter colored than the body of the rhizome. The odor is fetid, the taste acrid; both are lessened by drying and progressively diminish with time, so that the dried rhizome should not be kept longer than a single season. This acrimony is entirely absent in the decoction. The seeds are very acrid, and, though inodorous when whole, give out, when bruised, the peculiar odor of the plant.

The rhizome is affirmed to be antispasmodic and narcotic; occasioning nausea and vomiting, with headache, vertigo, and dimness of vision. It has been used with alleged success in *asthma, chronic catarrh, chronic rheumatism, chorea, hysteria, and dropsy*. Dose, of powder, from ten to twenty grains (0.65–1.3 Gm.), increased *pro re nata*.

Dragon's Blood. *Sanguis Draconis*. *Sang-dragon*, Fr. *Drachenblut*, G. *Sangre de drago*, Sp.—This is a resinous substance obtained from the fruit of several species of *Dæmonorops*, especially *D. Draco* (L.), Blume (*Calamus Draco*, L.) (Fam. Palmaceæ), small palms, growing in Siam, the Molucca Islands, and other parts of the East Indies. On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing, or shaking in a bag, or by exposure to the vapor of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms: sometimes in small oval masses (*tear dragon's blood*) of a size varying from that of a hazelnut to that of a walnut, covered with the leaves of the plant, and connected in a row like beads in a necklace; sometimes in cylindrical sticks, eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. In both these forms it is of a dark reddish-brown color, opaque, and readily pulverizable, affording a fine scarlet powder. It sometimes comes also in the form of a reddish powder. An inferior kind, said to be obtained by boiling the fruit in water, is in flat circular cakes (*cake dragon's blood*), two or three inches in diameter and half an inch thick. This also yields a fine red powder. A fourth variety, much inferior even to the last mentioned, is in large disks, from six to twelve inches in diameter by an inch in thickness, mixed with various impurities, as pieces of the shell, stem, etc., and supposed to be derived from the fruit.

According to the British Resident at Pontianak (1891), dragon's blood is sent into commerce from Pontianak, first, in flat cakes of various dimensions; second, in small cakes from three to seven inches long and an inch wide; third, in long pipes, while the regular cakes of dragon's blood, three inches wide, three inches long, and a quarter-inch thick, are manufactured at Singapore. One substance known by the name of dragon's blood is derived by exudation from the trunk of *Draecena Draco*, L. (Fam. Liliaceæ), a large tree inhab-

iting the Canary Islands and the East Indies, and another from *Pterocarpus Draco*, L. (Fam. Leguminosæ), a tree of the West Indies and South America, by incision into the bark; these, however, are little known in commerce. *Drop dragon's blood* is the product of the *Draecena schizantha*, Baker (Fam. Liliaceæ), of Socotra. It is occasionally seen in the London market. It is in small tears and fragments, seldom exceeding an inch in length, has a clean glassy fracture, and in thin pieces is transparent and of a splendid ruby color. It may be distinguished from true dragon's blood by the absence of shell-like scales, and by not evolving the irritating fumes of benzoic acid when heated.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to Herberger, it consists of 90.7 parts of a red resin, which he calls *draconin*, 2.0 of fixed oil, 3.0 of benzoic acid, 1.6 of calcium oxalate, and 3.7 of calcium phosphate. Tschirch (*Harze und Harzbehälter*, 1900, p. 189) has made an elaborate study of dragon's blood, and finds 2.5 per cent. of *draco-alban*, $C_{20}H_{40}O_4$, a white substance melting with decomposition at about 200° C.; 13.58 per cent. of *draco resen*, a yellow resinous substance of the formula $C_{26}H_{44}O_8$, and 56.86 per cent. of *draco resin*, a resin ester or mixture of esters, *benzoic dracoresinotannol ester* and *benzoylactic dracoresinotannol ester*, and 18.4 per cent. of insoluble substances. It was formerly employed in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart color to plasters.

Drosera. *Sundew*. *Herba Rorellæ*. *Rossolis*. *Rosée du Soleil*, Fr. *Sonnenhau*, G.—*Drosera rotundifolia*, L., and *D. longifolia*, L. (Fam. Droseraceæ), are said to be useful in *phthisis*, but they are probably of no value. (See *Proc. A. Ph. A.*, xxvii, 225.)

Duboisia. *D. myoporoides*, R. Br. (Fam. Solanaceæ), is a tall, glabrous shrub or small tree, which is a native of Australia, New South Wales, New Caledonia, and Queensland. The medicinal properties of this plant were made known by Baron von Mueller, who received the leaves from J. Bancroft. The alkaloid *duboisine* was discovered in the leaves by A. W. Gerrard (*P. J.*, viii, 787). For his method, see 16th ed. *U. S. D.*; also, for an account of the chemical and medicinal properties of this alkaloid, and its relations to atropine, see *Belladonna*, page 227.

According to the researches of Jos. Lanterer (*L. L.*, 1896), the old leaves and twigs of *Duboisia myoporoides*, R. Br., contain hyoscyamine, the fresh young leaves scopalamine, the dried leaves being stronger than are belladonna leaves, and yielding 0.97 per cent. of alkaloid. *Duboisia Leichhardtii*, F. Muell., is said to be still richer in alkaloid, which is chiefly amorphous scopalamine; while the leaves of *Datura arborea*, L. (*Brugmansia arborea*, Steud.), and of *D. cornigera*, Hooker (*Brugmansia Knightii*, Hort.), natives of South America acclimatized in Queensland, contain a mixture of hyoscyamine and atropine.

D. Hopwoodii, F. Muell., is the source of *pituri*, a narcotic stimulant largely used by the natives of Central Australia. The drug itself is a fine powder, composed of the leaves and twigs which are gathered during the month of August, while the flower is in bloom, and are put up in various forms of circular mats about six inches in diameter.

The natives smoke and chew pituri, and it is alleged to have a powerfully stimulating effect, assuaging hunger, and enabling those who are its devotees to perform much labor and go long journeys with but little food. Pituri yielded to A. W. Gerrard minute quantities of an alkaloid which he believed to be identical with nicotine, but Liversidge has shown that the liquid, acrid alkaloid, *piturine*, $C_{12}H_{16}N_2$, is distinct from nicotine. (*Proc. Roy. Soc. N. S. W.*, 1880.) Pituri contains from 1 to 2½ per cent. of the alkaloid.

Echinacea. *Brauneria pallida* (Nutt.), Britton (*Echinacea angustifolia*, DC., *Rudbeckia pallida*, Nutt.). *Nigger-head*, *Sampson-root*, *Pale Purple Cone-flower*.—This composite plant, a native of the prairie region of America west of Ohio, has been introduced by the so-called eclectic physicians as a remedy in divers dissimilar diseases. The root occurs in irregular cylindric pieces with shrunken epiderm wrinkled longitudinally or spirally, of a thickness ranging from one-quarter to one-half of an inch; the taste is at first sweetish and subsequently acrid and tingling. C. G. Lloyd believes that he has found in it minute quantities of an inactive alkaloid but that the active substance is a resinous body. (*Eclec. Med. Journ.*, 1897.) Echinacea is said by eclectic physicians to be an effective alternative in all septic diseases, also useful in *fermentative dyspepsia*, and in *intestinal indigestion*. It is also used by these practitioners locally in *mastitis*, *cancers*, *boils*, *abscesses*, and all forms of *infective wounds*. Lloyd states that the best preparation is the fluidextract, or tincture made with a menstruum of alcohol and water, four parts to one. The fluidextract is recommended in doses of from two to thirty minims (0.12 to 1.8 Cc.). J. C. Stinson (*T. G.*, 1900) recommended the local application of the undiluted fluidextract to the glans and its corona as an aphrodisiac, and E. Hale (*Lancet Clinic*, March, 1901) injects from two to six drachms (7.7 to 23.5 Gm.) of the extract into the rectum for the cure of *hemorrhoids*.

Brauneria purpurea (L.), Britton (*Rudbeckia purpurea*, L., *Echinacea purpurea*, Moench), *Black Sampson*, *Purple Cone-flower* (Virginia to Illinois and southward to Louisiana), has similar properties to *B. pallida*, and is similarly used.

Eggs.—The egg of the ordinary hen consists of an exterior covering, the shell; a white, semi-opaque membrane; the white; and the yolk.

The shell—*testa ovi* or *putamen ovi*—consists, according to Vauquelin, chiefly of calcium carbonate, with animal matter, and a minute proportion of calcium phosphate, magnesium carbonate, ferric oxide, and sulphur. When exposed to a high degree of heat in the open air, the carbon dioxide is driven off, the animal matter consumed, and the lime left nearly pure. The membrane lining the shell appears to be of an albuminous nature. The white—*albumin* or *albumen*, Br. 1898—is a glairy viscid liquid, contained in very delicate membranes, without odor or taste, readily soluble in water, coagulable by the stronger acids, by alcohol, and by a heat of 56° C. (132.8° F.). Exposed in thin layers to a current of air, it becomes solid, retaining its transparency and solubility in water. By coagulation it is rendered white, opaque, and insoluble. At a temperature of 100° C. (212° F.), one part of it renders opaque one thousand parts of water in which it has been dissolved. It contains, according to Bostock, in 100 parts, 85 of water, 12 of pure albumin, 2.7 of mucus or uncoagulable matter, and 0.3

of salts, including sodium hydroxide and traces of sulphur. The white of eggs is precipitated by stannous chloride, gold chloride, lead subacetate, copper sulphate, corrosive sublimate, and tannin. When kept in the fluid state it soon putrefies; but if carefully dried without coagulation it may be preserved unaltered a long time, and may be readily redissolved in water.

The yolk—*vitellus*, U. S. 1890—is inodorous, of a bland oily taste, and forms an opaque emulsion when agitated with water. By heat it is coagulated into a granular solid, which yields a fixed oil by expression. The researches by Gobley and others have established the constitution of the yolk about as follows: water, 51.8 per cent.; vitellin, 15.8 per cent.; nuclein, 1.5 per cent.; palmitin, stearin, and olein, 20.3 per cent.; cholesterolin, 0.4 per cent.; phosphoglyceric acid, 1.2 per cent.; lecithin, 7.2 per cent.; cerebrin, 0.3 per cent.; coloring matter, 0.5 per cent.; salts, 1.0 per cent. (König, *Nahrungs- und Genussmittel*, 180.) Vitellin belongs to the class of globulins, and, while not precipitated from its solution by sodium chloride, is precipitated completely on saturation of its solution with ammonium sulphate. Chevreul states that there are two coloring principles, one reddish containing iron, the other yellow and similar to the coloring matter of bile. The former is more difficultly soluble in ether than the latter. (*N. R. Pharm.*, 1867, xvi. 697.) It is said that the yolk may be kept for a considerable time without observable change by adding to it 5 per cent. of sodium sulphate, in powder or concentrated solution. Granules have been found, with the aid of the microscope, in the yellow of the egg, which are rendered blue by iodine, and have all the other properties of the starch granules. (*J. P. C.*, Oct. 1868, 261.) See *Glyceritum Vitelli*, page 860.

The white of egg is used chiefly for the clarification of liquids, which it effects by involving, during its coagulation, the undissolved particles, and rising with them to the surface, or subsiding. It is highly recommended as an antidote for corrosive sublimate and copper sulphate, with which it forms insoluble and comparatively inert compounds. It is sometimes also used for the suspension of insoluble substances in water, but is inferior for this purpose to the yolk, and even to mucilage of gum arabic. Agitated briskly with a lump of alum, it coagulates, at the same time dissolving a portion of the alum, and thus forming the so-called *alum curd*, which is used between folds of gauze over the eye, in some states of *ophthalmia*. It is also used in the official pepsin valuation.

The yolk in its raw state is thought to be laxative. In pharmacy, the yolk is highly useful as an intermedium between water and insoluble substances, and is to be preferred to the white in preparing emulsions.

Egols.—This name has been applied by E. Gautrelet (*C. R. A. S.*, 1899, 11) to a large series of substances introduced by him. They are *o-nitro-parasulphonates* of phenol, cresol, and thymol, in chemical combination with mercury and potassium. The egols are permanent compounds which crystallize with difficulty in rhombohedra, but which occur in commerce as reddish-brown powders, soluble in any proportion of water, forming odorless and tasteless solutions, neutral in reaction, and free from caustic or irritant character. In solutions of 0.4 per cent. they are said to be actively inhibitory to the growth of germs, and

in stronger solutions powerfully bactericidal. It is claimed for them also that they are not poisonous to man, although when given in overdoses they sometimes act as an emetic.

Eigones.—This name has been given to certain albuminous compounds of iodine and bromine which, when taken into the alimentary canal or brought in contact with wounds or ulcerated surfaces, undergo decomposition with liberation of their active substances.

Bromeigone is a white, almost odorless, and tasteless powder, insoluble in water, and contains on an average 11 per cent. of bromine in organic combination.

Iodine eigones: *Alpha-eigone* is a compound of iodine and albumin and appears as a light brown powder without odor or taste; contains about 20 per cent. of iodine. *Alpha eigone-sodium* is a light colored, almost white, powder, containing about 15 per cent. of iodine. It is moderately soluble in cold and more readily in hot water. *Beta-eigone* is a *peptonized iodized iodoeigone*, readily soluble in water; eigone soap contains 5 per cent. of *iodoeigone*. Internally the iodine eigones have been used in doses of from six to nine grains (0.4–0.6 Gm.), best given in the form of pill, in *syphilis, rheumatism, bronchitis, asthma*, and other conditions in which potassium iodide is employed. They produce the ordinary symptoms of iodism when given in sufficient amount, but are said to have the great advantage over the older iodides of not irritating the stomach. As a local application they are employed in all forms of external infective wounds, in *nasal catarrh, tuberculosis, ulcers, abscesses*, and in the class of cases in which iodoform has been hitherto employed. It is claimed for them that they are innocuous, but it is certain that if they do undergo decomposition in the wound with the liberation of iodine they must be capable of producing symptoms similar to those which have so often followed the surgical use of iodoform.

Peptoneigone is a peptonized bromine albumin compound which is comparatively readily soluble in water. It also contains about 11 per cent. of combined bromine. It is odorless and tasteless. Traces of hydrogen bromide are sometimes present as an impurity. The bromeigones are supplied commercially in the form of *bromeigone, brompeptone* or *peptonebromeigone*, and are odorless, tasteless powders. Bromeigone is insoluble, peptonebromeigone is soluble in water. The bromeigones have been given internally as substitutes for the bromides in various diseases. The dose of each of them varies from two grains (0.13 Gm.) up to a daily dose of a drachm (3.9 Gm.) in *epilepsy*.

Ektogan is the name given to *zinc peroxide*, ZnO_2 , which has been recommended for external application; it liberates hydrogen dioxide. It is a yellow, odorless, and tasteless powder.

Embelia. *Br. Add.*—"The fruit of *Embelia Ribes*, Burmann, and of *Embelia robusta*, Roxb." This berry-like fruit grows in large bunches; it is of a dull red color, is about one-sixth of an inch in diameter and contains a reddish, horny seed dotted with whitish spots. C. H. Warden separated from it (*P. J.*, Jan. 1888) the brilliant golden spangles of embelic acid, and L. Scott has determined the presence in the fruit of a volatile oil and an alkaloid *chrestembine*. Under the names of *viranga, vaypirang, birang-i-kabuli* it has long been employed in India as an anthelmintic and has found its way into European commerce. It is sometimes used to adulterate cube

and black pepper. It has but slight laxative properties, so that it is better to follow it by a purgative. It is especially tenicidal, the *tape worm* being expelled dead. One to four drachms (3.9–15.5 Gm.) of the powder may be given in milk early in the morning. Warden has found that *ammonium embelate* is an effective *tenicide* in doses of three grains (0.2 Gm.) for children and six grains (0.4 Gm.) or more for adults. As it is nearly tasteless and soluble it may be readily administered in syrup.

Emery. *Lapis Smiridis, s. Smiris.* *Emeri, Corindon granuleux ferrière, Fr. Smirgel, Schmirgel, G.*—A very hard mineral, the powder of which is capable of wearing down all other substances except the diamond. It was formerly derived almost solely from the island of Naxos, in the Grecian Archipelago. According to Landerer, it has been found in Asia Minor and the Morea, and it occurs in Chester, Hampden County, Mass. (See J. Lawrence Smith, *Am. J. Sci.*, 1866, xlii.) Emery is pulverized by grinding it in a steel mill, and the powder is kept in commerce of different degrees of fineness. It is used for polishing metals and hard stones. Compact corundum is now ground extensively for the manufacture of emery wheels, etc. Corundum is found abundantly in Northern Georgia, in North Carolina, and in Chester County, Pennsylvania, U. S. Emery is being steadily replaced in use by the new product of the electric furnace, *carborundum*.

Emodin.—This compound, now recognized as *trioxymethylantraquinone*, $\text{C}_{14}\text{H}_4(\text{CH}_3)(\text{OH})_3\text{O}_2$, (see *Rheum*, 1059), as prepared from aloes, forms orange-red needles, melting at 216°C . (420.8°F). It may be prepared from barbaloin by extraction with ether, in which the emodin is soluble, while the aloin is left undissolved. This ethereal extract turns red on the addition of ammonia (Borntraeger's reaction for oxymethylantraquinones).

According to Tschirch, aloë-emodin is a certain, moderate purge in man, in doses of one and three-tenths grains (0.085 Gm.), frangula emodin having about the same purgative strength. In view of the fact that in Barbados aloes there is only 2 per cent. of aloë-emodin, that in rhubarb there is only 2 per cent. of rhubarb-emodin with 4 or 5 per cent. of chrysophanic acid, and that in senna the percentage of emodin is much less than these figures, the belief of Tschirch that emodin is the active principle of these drugs seems highly improbable. It constitutes only a fraction of aloin, but has to be given in four or five times the dose of aloin to have purgative effect. In Tschirch's estimation, the superior activity of crude drugs is due to the presence in them of educts produced by oxidation or hydrolysis from the oxymethylantraquinone. The experiments of Asher, upon which Tschirch bases his belief that in the emodin group the purgation is caused by local stimulation of the nerve endings in the intestinal mucous membranes and reflexly excited peristalsis, were certainly not sufficient in number or thoroughness to establish the correctness of the theory.

Endermol is a compound ointment vehicle containing hydrocarbons of the paraffin series and stearic acid amide. (Coblentz, *M. News*, Sept. 3, 1904.)

Eosin. $\text{C}_{20}\text{H}_8\text{Br}_2\text{O}_5$.—A dye obtained by the action of phthalic anhydride upon phenols and introduction of bromine into the product. When phthalic anhydride acts upon resorcinol, C_6H_4

(OH)₂, in the presence of a dehydrating agent like sulphuric acid or stannic chloride, at a temperature of 120° C. (248° F.), there is formed a compound *resorcinophthalein*, C₂₀H₁₂O₅, better known as *fluorescein*. By the action of bromine upon this is formed *tetrabrom-fluorescein* or *eosin*, C₂₀H₂Br₄O₅. Soluble eosin is the potassium salt of this compound, C₂₀H₂Br₄O₅K₂. It forms a bronze-colored crystalline powder having a strong green reflection. Its solution in water is a red liquid having a fine green fluorescence. On the addition of hydrochloric acid the fluorescence is destroyed, the liquid becoming yellow. Eosin is largely used at present as a dye; to make a brilliant red ink, dissolve 5 grains of eosin and 10 grains of gum arabic in a fluidounce of water.

Ephedra. *Ephedra vulgaris*, L. (Fam. Gnetales).—Nagai has extracted from this Japanese plant an alkaloid, *ephedrine*, which, according to Kinnosuke, produces in the lower animals acceleration of the pulse, with lowering of the blood pressure, elevation of the rectal temperature, dilatation of the pupils, convulsions, and death by arrest of the heart and respiration. (B. K. W., No. 38, 1887.) Scriba found that a 10 per cent. solution dilates the pupil with certainty, in from forty to sixty minutes, without irritation, the dilatation not being complete, and the accommodation not at all or only slightly affected, and the pupils returning to normal in from five to twenty hours. An alkaloid has also been discovered in *Ephedra distachya*, L., a shrub whose branches and root are used in Siberia as a powerful remedy in *gout* and *syphilis*. According to Kobert, this alkaloid is essentially different from *ephedrine*, in not being mydriatic or poisonous. P. Spehr (A. J. P., 1892, 234) considers that *E. vulgaris* contains two alkaloids, *ephedrine* and *pseudo-ephedrine*, isomeric and of the formula C₁₀H₁₅NO, while *E. monostachya* contains a crystalline base melting at 112° C. (233.6° F.) and having the formula C₁₂H₁₉NO. This latter, as stated by Kobert, is not mydriatic or poisonous. According to Günsberg, *pseudoephedrine* is a powerful mydriatic, its 10 per cent. solution causing in fifteen minutes dilatation of the eye through excitement of the sympathetic nerve.

Ephedra nevadensis, S. Wats., and *E. antisiphilitica*, C. A. Meyer, which grow abundantly in the extreme Western United States, are much used under the names of *caynote*, *canutilo*, *whorehouse tea* as a remedy in *gonorrhœa*. Loew thinks that their virtues reside in a peculiar tannin. Dose, of fluidextract, from one to two fluidrachms (3.75–7.5 Cc.). In Texas *E. trifurca*, Torr., is similarly employed.

Epicarin.—A condensation product of *creosotic acid* and naphthol which, according to Eichen-grün, is *β-oxy-naphthyl-o-oxy-meta-toluylic acid*

thus:
$$\text{C}_6\text{H}_5-\begin{array}{c} \text{COOH} \\ | \\ \text{OH} \\ | \\ \text{CH}_2-\text{C}_{10}\text{H}_6\text{OH} \end{array}$$
 Epicarin forms

slightly yellowish crystals or powder, with a faint odor, melting at 199° C. (390.2° F.), difficultly soluble in water but freely soluble in alcohol and ether as well as in soaps. It is said to be slightly poisonous, and was primarily introduced into veterinary medicine especially for the treatment of *mange*, but has been used by Kaposi, Monti, and other dermatologists in *scabies*, *ring-worm*, *prurigo*, and allied skin diseases as a substitute for naphthol. Its application is sometimes followed by irritation, which, though usually slight, may lead to papular and eczematous eruptions. It is

claimed that the remedy is less poisonous than naphthol. In Kaposi's clinic no toxic symptoms followed covering the entire body of children with 10 per cent. ointment. Five to twenty per cent. ointment is used *pro re nata*.

Epidermin.—A surgical dressing made by fusing 15 Gm. of white wax, and triturating in a warm mortar with 15 Gm. of powdered acacia until uniform, and adding a boiling mixture of 15 Gm. each of water and glycerin, and stirring until cold. Valentine and Schwarz have given the name *epidermin* to an ointment vehicle said to be composed of fluorxytol and difluordiphenyl.

Epigæa. *Epigæa repens*, L. *Trailing Arbutus*. *Ground Laurel*. *Mayflower*. *Gravel plant*.—This is a small trailing ericaceous plant, with woody stems from six to eighteen inches long, entire, cordate-ovate leaves, and small, very fragrant flowers, which appear early in the spring. It is found in the woods, and grows on the sides of hills with a northern exposure. Darlington states that the plant has been supposed to be injurious to cattle, when eaten by them. (*Flora Cestrica*, 259.) Jefferson Oxley has found in this plant *arbutin*, C₁₂H₁₆O₇, *urson*, C₂₀H₃₂O₃, *ericolin*, C₃₄H₅₆O₂₁ (the same constituents as are in *uva ursi*), tannic and formic acids, and a principle allied to gallic acid. (A. J. P., xlv. 253.) Thal gives the simpler formula C₂₆H₃₀O₃ to *ericolin*. Eli Ives of New Haven, Connecticut, in 1849, highly commended *epigæa* as a substitute for *uva ursi*, and we now know that the two drugs contain the same active principles. The decoction of the leaves and stem may be used freely.

Epilobium. *Epilobium angustifolium*, L. *Chamænerion angustifolium* (L.), Scop. *Willow-herb*. *Herbe de St. Antoine*, Fr. *Weidenröschen*, Antonskraut, G. (Fam. Onagraceæ).—There are several indigenous species of *Epilobium*, which have the common name of willow-herb from the resemblance of their leaves to the willow, and probably have nearly identical properties. The *E. angustifolium*, L., is the largest of them. Its leaves and roots are said to be demulcent, tonic, and astringent, and yield their virtues to water and alcohol. They are used by the eclectics, generally and locally, in decoction, infusion, or cataplasm, as astringents. Oliver reports (B. M. J., ii. 1897) violent poisoning with epileptiform convulsions caused by *E. hirsutum*, L. Under the name of *Kaporie tea* the leaves of *E. angustifolium* and of *E. hirsutum* are largely used in Russia as a beverage.

Epiosin, C₁₆H₁₂N₂, crystallizes in glassy prisms melting at 195° C. (383° F.), readily soluble in alcohol and chloroform. It is a synthetic compound, produced by E. Vahlen, who claims for it the anodyne action of morphine without its objectionable after results. Chemically it is a *methyl-diphenylenamido-azol*. (A. E. P. P., 47 to 368.)

Epithol.—*Epithol gold* and *epithol silver* are finely powdered copper and tin, which have been used in veterinary medicine by L. Hoffmann as a local application to wounds. (B. Ther. W., 1902.)

Equisetum. *Equisetum hyemale*, L. *Horsetail*. *Scouring Rush*. *Prêle*, Fr. *Schachtelhalm*, G. (Fam. Equisetaceæ).—An indigenous plant, with slender annual stems from a foot and a half to three feet high, growing abundantly in the Northern States, and preferring wet places, as the banks of streams, etc. The plant derives its name of scouring rush from its use in scouring, for which it is fitted by the silicious character of the stems. Examined by F. J. Young (A. J. P., 1886, 419), it yielded to petroleum benzin as a solvent 1.4 per

cent. of a brownish-green, semi-liquid, fixed oil, which was readily saponified. It also contained a green semi-solid resin, sugar, and mucilage. The infusion of the whole plant has the reputation of being diuretic, and is used sometimes in *dropsical* and *renal diseases*.

Erechthites. *Erechthites hieracifolia* (L.), Raf. *Fire-weed*.—An annual indigenous composite plant, growing in moist woods and recent clearings, and having a rank somewhat aromatic odor. Its taste is bitterish, slightly acid, and disagreeable. It yields its virtues to water. It has been especially recommended in *dysentery*. It is prone to infest the peppermint fields of Michigan, and its oil is said sometimes to deteriorate the oil of peppermint from that region. It has been shown, however, that *Leptilon canadense* (L.), Brit., is far more injurious.

Ergotinol.—*Liquor Ammonii Ergotinatis*, a preparation of ergot made by Vosswinkel, sixteen minims (1 Cc.) corresponding to eight grains (0.5 Gm.) of extract of ergot. The dose for subcutaneous injection is sixteen minims (1 Cc.). It is recommended in excessive *menorrhagia*.

Erigeron. *Fleabane*. *Scabious*. *Sweet Scabious*. *Daisy Fleabane*. *Herbe d'érigeron*, *Herbe de Vergerette*, Fr. *Berufkraut*, G.—Under this name the U. S. Pharmacopœia of 1870 recognized the herbal portions of *Erigeron annuus* (L.), Pers. (*E. heterophyllus*, Muhl.) and *E. philadelphicus*, L. (Fam. Compositæ.)

E. annuus is a biennial herbaceous plant, belonging both to North America and to Europe. The lower leaves are ovate, acute, deeply toothed, with long winged footstalks; the upper are lanceolate, acute, deeply serrate in the middle, and sessile; the floral leaves are lanceolate and entire; all, except the radical, are ciliate at the base.

Erigeron ramosus (Walt.), B. S. P. (*E. strigosus*, Muhl.) grows with *E. annuus*, and is frequently collected with it. It is distinguished by its leaves being nearly entire, and by both stems and leaves being almost smooth or furnished only with minute appressed hairs.

Erigeron philadelphicus, L. *Philadelphia fleabane* is perennial and herbaceous, with a branching yellowish root, and from one to five erect stems. The whole plant is pubescent. The lower leaves are ovate-lanceolate, nearly obtuse, ciliate on the margin, entire or marked with a few serratures, and supported on very long footstalks; the upper are narrow, oblong, somewhat wedge-shaped, obtuse, entire, sessile, and slightly embrace the stem; the floral leaves are small and lanceolate.

The three species are abundant in the middle portions of the United States, grow in open fields, and are probably of identical medicinal value. They are popularly known as *scabious*. The whole herb is used, and should be collected while the plants are in flower. It has a feebly aromatic odor and bitterish taste, and imparts its properties to boiling water. F. L. John of Philadelphia, obtained from *E. philadelphicus* a volatile oil by distillation, but in exceedingly small proportion, forty-five pounds of the herb having yielded only half a drachm of the oil. As described by Procter, this is of a greenish-yellow color, a powerful, penetrating, aromatic odor, and a bitterish, pungent, disagreeable taste. It is more viscid than the oil of *Leptilon canadense*, has a higher sp. gr. (0.946), and contains more oxygen. (*A. J. P.*, xvii. 105.) Fleabane is diuretic and stomachic, and has been used in *gravel* and in *dropsy*.

The U. S. Pharmacopœia also formerly recognized, as *Erigeron canadense*, the plant known to botanists as *Leptilon canadense* (L.), Britt. (*Erigeron canadense*, L.) *Horseweed*. *Mare's tail*. *Fire-weed*. *Butter-weed*. *Colt's-tail*. *Canada fleabane* is an indigenous annual plant; an allied species, *L. divaricatum* (Michx.), Raf. (*Erigeron divaricatum*, Michx.), is not more than from three to twelve inches high, and has an erect smooth stem, less branched than the preceding, with all its leaves entire, and scabrous on the margin. The panicle is simple, and the peduncles filiform, nearly naked, divaricate, each bearing two or three flowers.

Canada fleabane is very common throughout the northern and middle sections of the United States, and has become naturalized in many parts of Europe. It abounds in neglected fields, and is reported to be a very troublesome weed on the peppermint plantations of the West. It blooms in July and August. The plant, all parts of which are medicinal, should be collected while in flower. The leaves and flowers are said to be the most active parts. It has a characteristic odor, and a bitterish, acid, somewhat astringent taste. Among its constituents, according to De Puy, are bitter extractive, tannin, gallic acid, and volatile oil. Both alcohol and water extract its virtues. Its acrimony is diminished by decoction, in consequence, probably, of the escape of the oil, upon which its virtues in part depend. (See *Oleum Erigerontis Canadensis*.) According to De Puy, Canada fleabane is diuretic, tonic, and astringent; and useful in *dropsical complaints* and *diarrhœa*. It has been given in substance (*dose*, a drachm, or 3.9 Gm.), infusion, tincture, or extract (*dose*, ten grains, or 0.65 Gm.), but the oil is the only proper preparation. The oil is of value in *uterine*, *pulmonary*, and other *internal hemorrhages*, in *doses* of from five to fifteen minims (0.3–0.9 Cc.), every two hours.

Eriobotrya. *Eriobotrya japonica*, Lindl. *Loquat*. (Fam. Rosacæ.)—The seeds and leaves of this tree are said to contain amygdalin and emulsin, and to yield hydrocyanic acid in poisonous quantities. (*P. J.*, Aug. 1885.)

Erodium. *Erodium Cicutarium* (L.), L'Herit. *Storks-bill*.—An annual hairy plant belonging to the Geraniacæ. It is highly recommended by W. Abbotts Smith in *dropsy*. (See *Am. J. M. S.*, 1865.)

Eryngium. *Eryngium aquaticum*, L. *Button Snakeroot*. *Corn Snakeroot*. *Rattlesnake's Master*.—The *button snakeroot* or *water eryngo* is an indigenous umbelliferous plant which grows in low wet places, as far south as Florida and Texas. The root, which is the medicinal portion, has a bitter, pungent aromatic taste, provoking, when chewed, a flow of saliva. It is said to be diaphoretic, expectorant, in large *doses* emetic, and the plant has been used as a substitute for *senega*. (Bigelow.)

Erythrina.—The bark of the Australian species of this genus, *Erythrina Broteroi*, is said to contain an alkaloid, *erythrinine*, while the Mexican species, *Erythrina coralloides*, DC., bears poisonous seeds in which Altamirano has found *erythroidine*, a powerful paralyzant of the motor system, *erythroresin*, an emetic, *coralin* and *erythric acid*. The extract has been suggested as a substitute for *curare*. (*B. S. Ph. Br.*, 1900.)

Erythrina Lithosperma, Blume. (*Hypaphorus subumbrans*, Hasskl.)—From the seeds of this beautiful leguminous tree, largely grown for

shade in the coffee gardens of Java, P. C. Plugge has obtained *hypaphorine*, a tetanizing alkaloid. (*A. E. P. P.*, xxxii.)

Erythrol Tetranitrate. $C_4H_6(NO_3)_4$.—Erythrol tetranitrate is solid and crystalline, and melts at $61^\circ C.$ ($142^\circ F.$). When pure it is colorless, and if kept in a dark and moderately cool place is fairly stable. If exposed to warmth, and especially sunlight, it rapidly undergoes decomposition, turning yellow and giving off nitrous fumes. It is also capable of rapid decomposition, and death has been caused by the explosion following its trituration in a mortar with glucose. (*B. M. J.*, i, 1896.) Its solubility in water is slight, but it dissolves readily in alcohol and in ether. It is a vaso-dilator, and belongs to the group of which glyceryl trinitrate (glonoin) or nitroglycerin is the representative. Blood pressure experiments show that the nitrates of erythrol and mannitol have a less marked but more prolonged action than those of glycerol and glycol. In man the effects of the remedy are said not to be apparent in less than half an hour and to last for over an hour. It may be used in all cases for which glyceryl trinitrate is employed, and has been especially commended in *angina*. Its alcoholic solution is explosive, so that it should always be used in tablets, in preparing which great care is necessary. *Dose*, from a half to one grain (0.032 – 0.065 Gm.).

Erythronium. *Erythronium americanum*, Ker. (*E. lanceolatum*, Pursh.).—This is an indigenous, perennial, liliaceous plant, sometimes called, after the European species, *dog's-tooth violet*. It grows in woods and other shady places from Nova Scotia to Florida and west to Minnesota and Arkansas. It flowers in the latter part of April or early in May. All parts of it are active. In the *dose* of twenty or thirty grains (1.3 or 2.0 Gm.) the recent bulb is emetic. The leaves are said to be more powerful. The activity of the plant is diminished by drying.

Eschscholzia. *Eschscholzia californica*, Chamisso.—Attention has been brought to this Californian member of the Papaveraceæ, as a powerful soporific and analgesic, which is free from the disadvantages of opium. Bardet and Adrain (*G. H. M. C.*, Nov. 1888) assert that they have obtained a glucoside, an alkaloid, and morphine in the proportion of from five to six grains in two pounds of the dried product. According to Fischer and Tweeden, there are seven alkaloids in *Eschscholzia californica*; *protopine*, β - and γ -*homochelidonine*, "alkaloid *a*," "alkaloid *b*," *sanguinarine* and *chelerythrine*. As far as could be determined from the small quantities obtained, the alkaloids designated as *a* and *b* differ from any other alkaloids thus far known. (*Ph. Archiv.*, 1902, No. 7.) The narcotic power of the drug seems to be very weak, since, according to Bardet, three drachms were necessary to kill a rabbit. Ter-Zakariant (*G. M. P.*, Feb. 1889) states that the alcoholic extract acts as a respiratory depressant and narcotic, affecting in toxic dose also the spinal cord. Dujardin-Beaumetz has used the extract in commencing *doses* of twelve grains (0.78 Gm.), increasing to one hundred and eighty-five grains (12 Gm.) a day, and affirms that it is a harmless soporific and analgesic.

Ethoxycaine. $C_{10}H_{14}N_4O_3$, is prepared by boiling 3 parts of bromocaine with 2 parts of potassium hydroxide and 10 parts of alcohol. It forms crystals fusing at $140^\circ C.$ ($284^\circ F.$); is difficultly soluble in water and ether, easily solu-

ble in hot alcohol, insoluble in alkalies, soluble without decomposition in cold diluted hydrochloric acid; on warming it is decomposed. Filehne (*A. Phys.*, 1886) finds that ethoxycaine has upon frogs and rabbits a narcotic effect. From seven to ten grains of it produced in man vertigo, intellectual torpor, and sometimes pain in the head. Dujardin-Beaumetz (*B. G. T.*, March, 1886) finds that it acts in the guinea pig as a narcotic and diuretic, and has given it for *headache* in *doses* of from three to fifteen grains (0.2 – 1.0 Gm.) a day, in capsules or dissolved in water by means of sodium salicylate. Cases of painful *zona*, *migraine*, and *nervous headaches* were relieved. The larger doses produced gastric irritation.

Ethyl Bromide. *Bromide of Ethyl.* *Hydrobromic Ether.* *Ether Bromatus.* *Bromure d'éthyle*, Fr. *Bromäthyl*, G. C_2H_5Br .—This ether was discovered by Sérullas in 1827, who prepared it by acting on alcohol with bromine in the presence of phosphorus. (*Ann. Ch. Phys.*, xxxiv. 99.) Personne suggested the use of amorphous phosphorus, as less dangerous than ordinary phosphorus and more convenient to manipulate. (*O. R. A. S.*, iii. 468.) A process was also recommended by Remington, based upon Personne's suggestion. (*Proc. A. Ph. A.*, 1877.) De Vrij proposed to decompose potassium bromide with sulphuric acid in the presence of alcohol, and a modification of his method is now generally employed. We have obtained good results from the following:

Take of potassium bromide (not powdered) 58 parts; sulphuric acid, sp. gr. 1.838, 44 parts; alcohol (clean), 95 per cent., 44 parts; water, 28 parts. Pour the water into a flask having double the capacity of the liquid ingredients above, and gradually add the acid; when the liquid has become cool, add the potassium bromide, and having placed the flask in a sand bath, adjust a thermometer, and with a bent glass tube connect the flask with a well cooled condenser; insert a narrow glass tube in the cork of the flask, and by means of a short rubber tube connect it with a narrow glass tube which is terminated by a siphon; the shorter limb of this siphon is inserted in the bottle containing the alcohol, which is elevated three feet or more above the flask. Heat the contents of the flask to $116^\circ C.$ ($240.8^\circ F.$), and having attached a screw pinch-cock to the short rubber tube of the siphon, allow the alcohol to drop or flow in a small stream into the flask, carefully regulating the rate of flow so that the temperature shall not fall below $100^\circ C.$ ($212^\circ F.$), nor rise above $116^\circ C.$ ($240.8^\circ F.$). When all the alcohol has passed into the flask, continue the distillation until the temperature rises to $116^\circ C.$ ($240.8^\circ F.$), and then disconnect the receiving flask. Agitate the distillate with an equal bulk of distilled water, to which has been added five parts of solution of sodium hydroxide (or sufficient to render the liquid slightly alkaline), and when the mixture has clearly separated into two layers, pour off the uppermost layer, and, having introduced the heavier liquid into a clean flask containing a few fragments of calcium chloride, redistill it. For other methods of manufacture, see *N. R.*, 1877, 200; 1879, 8; *A. J. P.*, 1879, 292; 1880, 248, 280, 298; also *Ph. Centralt.*, xxviii. 1887, 122. For L. Wolff's process for making it economically, see *A. J. P.*, 1880.

Ethyl bromide is a colorless, very volatile liquid, not inflammable, having an agreeable odor, and a hot, saccharine taste. Its sp. gr. is 1.450. It

boils at from 38°–39° C. (100.4°–102.2° F.). It is very sparingly soluble in water, freely soluble in strong alcohol and ether. When a small portion is evaporated from a porcelain plate by causing it to flow to and fro over the surface, little or no foreign odor is yielded as the last portions pass off, and the plate is covered with a slight deposit of moisture.

The ethyl bromide prepared from alcohol and bromine in the presence of amorphous phosphorus should not be used in medicine because of the possible presence of organic compounds of sulphur and arsenic. Shaken with distilled water, ethyl bromide should not show any acid reaction from hydrobromic acid, nor should it cause any appreciable turbidity with silver nitrate. Shaken with an equal volume of pure concentrated sulphuric acid, no color should develop even after an hour's time; otherwise ethylene bromide may be present. Dropped slowly into potassium iodide solution, the drops of the ethyl bromide should settle to the bottom of the vessel without developing any appearance of violet color, which would indicate free bromine. Ethyl bromide should be kept in amber-colored glass bottles, completely filled and well stoppered. (Fischer, *Die Neueren Arzneimittel*, 6te Aufl., 74.)

Some years ago ethyl bromide was proposed and largely used as an anæsthetic. In a series of experiments made with it at that time, H. C. Wood found that its action upon the heart is the same as that of chloroform, and that injected into the jugular vein it causes cardiac arrest. The occurrence of two deaths from it, one of them distinctly syncope, partly arrested its successful career, although it certainly acts very promptly and agreeably, and its influence passes off with extraordinary rapidity. Recently, professional attention has been strongly redirected to the bromide, and it is asserted that the evil effects produced in its early use were due to the presence of impurities, especially of ethylene bromide. Hamecker (*Internat. Klin.*, Dec. 20, 1891) affirms that in experiments upon the lower animals, made with pure ethyl bromide, death always occurred through arrest of the respiration, the heart continuing to beat from fifteen to nineteen minutes after cessation of the breathing.

In accordance with this, Gilles asserted in 1892 that in twenty thousand successive administrations with the ethyl bromide in Germany there had been no fatal results when a chemically pure bromide has been used. Since this assertion a number of deaths (five or six) have been reported, in which it has been distinctly proved that a pure ethyl bromide was given. Gurit (*Arch. f. Klin. Chir.*, lv.) puts the mortality rate at 1 in 5396 inhalations, and the studies of Wood and Cerna indicate that it is about as dangerous as chloroform. Moreover, it has been shown by Hennicke that the ethyl bromide undergoes decomposition with the liberation of bromine compounds in the system. We have at present no definite knowledge as to the action of these bromine compounds, but it is probable that they are capable of producing secondary changes in the organic structure, especially since cases have been reported by Reich and by Hatten of death from acute fatty degeneration after its inhalation. It has been largely used as a practical anæsthetic. (*S. Jb.*, Bd. cxvii. 234; Bd. cclx. 18.) The narcosis is said to be produced almost abruptly, with practically no stage of preliminary excitation and to be accompanied by little tendency to muscular relaxation.

Its effects pass off so suddenly as to endanger their continuance during the operation. On account of its loss by evaporation it is a very expensive anæsthetic. Ethyl bromide has been especially recommended for use in *parturition*, it being stated that it suspends the pain of the uterine contractions without influencing their force, and it has been employed to a considerable extent in cases when a brief anæsthetic is required. In using it, from two to four fluidrachms (7.5–15 Cc.) may be put upon an Allis inhaler or upon a napkin.

Ethyl Cyanide. *Hydrocyanic Ether. Propionitrile.* C_3H_5N , or C_2H_5CN .—This ether was discovered by Pelouze. It is formed by distilling a mixture of barium sulphovinate and potassium cyanide, or better, by the action of ethyl iodide on potassium cyanide in closed tubes at a temperature of 180° C. (356° F.). It is a colorless liquid, of an agreeable ethereal odor, soluble in alcohol, ether, and water, boiling at 98° C. (208.4° F.), and having the sp. gr. 0.78. *Ethyl cyanide* is very poisonous, but less so than hydrocyanic acid, with which it agrees in therapeutic action and dose.

Ethyl Fluoride.—*Fluoride of Ethyl*, C_2H_5F , is said to cause in animals violent excitement, followed quickly by death. For properties and method of preparation, see *Chem. News*, Jan. 1889, also *B. A. M.*, Mars, 1890.

Ethyl Formate. *Formic Ether. Ethyl-formic ester.*—A liquid with a peach-kernel odor, sp. gr. 0.937, soluble in ten parts of water. This compound is reputed to be useful in the treatment of infectious diseases of the respiratory organs.

Ethyl Iodide. *Hydriodic Ether. Ethyl-hydriodic ester. Iodure d'éthyle, Ether hydriodique, Fr. Jodäthyl, Jodwasserstoffäther, G.* C_2H_5I . This liquid may be obtained by gradually and cautiously mixing five parts of alcohol, ten of iodine, and one of phosphorus, and distilling. The residue of the distillation, as ascertained by D. K. Tuttle, is *ethylphosphoric acid*. Personne (*C. R. A. S.*, 51, 468) proposed to use amorphous phosphorus instead of the ordinary kind, thus avoiding danger. Five parts of amorphous phosphorus are added to 60 parts of 95 per cent. alcohol and 40 parts of iodine are added in small portions to the mixture poured into a retort. The whole is allowed to stand for twenty-four hours; attachment is made to a Liebig condenser, and the liquid distilled at a temperature not exceeding 80° C. (176° F.). The yellowish distillate is shaken with solution of acid sodium sulphite, and the layer of ethyl iodide washed repeatedly with water. It is then rectified after removing traces of water by shaking the ethyl iodide with dry calcium chloride. De Vrij recommends the following method for procuring ethyl iodide on a large scale. Absolute alcohol is to be saturated with dry hydrochloric acid gas, the liquid being kept well cooled, and the amount of the acid is to be determined in a sample. The liquid thus saturated is to be put into a retort, with as much potassium iodide as may be necessary to form potassium chloride; the mixture is to stand for a day, and is then to be submitted to distillation. Finally, the ether which comes over is to be washed and rectified. (See *A. J. P.*, 1859, 170.) Ethyl iodide is a colorless non-inflammable liquid, insoluble in water, with a penetrating ethereal odor and pungent taste. Its density is 1.92, and boiling point from 71°–72° C. (159.8°–161.6° F.). Exposed to the air it becomes red from the liberation of

iodine; the change in color is prevented by adding to the bottle containing it a globule of mercury. Huette has proposed this ether, placed under a layer of water, as a medicine, to be used by inhalation. Fifteen or twenty inspirations suffice to impregnate the system with iodine. It acts as a powerful anæsthetic, when inhaled for a sufficient time. It is said to increase the appetite, render the pulse fuller, and give vivacity to the feelings and activity to the intellect. (See *A. J. P.*, xxiii. 156.) James Turnbull of Liverpool, and Henry Fisher of New York, have used this ether by inhalation with satisfactory results in *chronic bronchitis* and *phthisis*. The dose is fifteen drops (0.75 Cc.), three or four times a day, inhaled from a handkerchief. Ethyl iodide often has an unpleasant odor from the presence of foreign substances which renders it offensive to patients. Phosphorus is a common and injurious impurity.

According to Linossier and Lannois (*S. M.*, 1897), ethyl iodide affords an excellent method of affecting the general system by external application. Absorption of the iodine is rapid; the liquid should be applied with a brush and then covered with paraffined paper; after applying two fluidrachms they recovered thirteen grains of iodine from the urine.

Ethylene Bromide. *Brom-ethylene.* *Æthylum Bromatum.* $C_2H_4Br_2$.—This is a colorless oily liquid smelling like chloroform, with a sweet burning taste. It boils at $131.6^\circ C.$ ($269^\circ F.$), and solidifies at $0^\circ C.$ ($32^\circ F.$) to a crystalline mass; sp. gr. at $20^\circ C.$ ($68^\circ F.$) 2.178. It is insoluble in water, miscible with alcohol in all proportions. In experiments made by Scherbatscheff (*A. E. P. P.*, 1902, vol. xlvii.) ethylene bromide was found not to act as a true anæsthetic in the lower animals, but to produce serious symptoms, usually ending in death. The chief medicinal importance of this agent grows out of its liability to be confounded with the ethyl bromide, death in this way having been produced. Ten fluidrachms of it were inhaled without the production of anæsthesia, followed by uncontrollable vomiting and complete suppression of urine. On account of its containing over 85 per cent. of bromine, Donath has used it in *epilepsy*. He gives it in an emulsion with oil, or mixed with almond oil in capsules. Children from eight to ten years begin with from ten to twenty drops (0.5–1.0 Cc.) of a 5 per cent. solution; the adult dose is six drops (0.3 Cc.) of ethylene bromide, three times a day. (See also *P. J.*, xxi. 1068.)

Eucaine. *Eucaine Hydrochloride.* *Alpha-Eucaine, Beta-Eucaine.*—Under the name of Eucaine Hydrochlorate, manufacturers have introduced into practical medicine two distinctly different substances, distinguishing them as Eucaine Hydrochlorate A, or *Alpha-Eucaine*, and Eucaine Hydrochlorate B, or *Beta-Eucaine*, producing much confusion in clinical reports.

Alpha-Eucaine, or the present *Eucaine*, is free from irritant properties, while *Beta-Eucaine*, which was formerly sold as eucaine, is so irritant that its use has been abandoned.

Eucaine Hydrochloride A, or *Alpha-Eucaine*, was first described. It is *n-methyl-benzoyltetramethyl-γ-oxypiperidincarbonylmethyl ester*. Eucaine Hydrochloride B, or *Beta-Eucaine*, is *benzoylvinyldiacetonalkamine*. The first of these has the formula $C_{19}H_{27}NO_4 \cdot HCl + H_2O$, and is a triacetoneamine derivative. Triacetoneamine by treatment with hydrocyanic acid, followed by boiling

with water, is converted into oxymethyl piperidincarbonic acid, and this by the introduction of the benzoyl and methyl groups into the base eucaine, which is then crystallized out as the hydrochloride. Eucaine B, on the other hand, is the benzoyl derivative of *vinyldiacetonalkamine*. Its formula is $C_{15}H_{21}NO_2 \cdot HCl$.

Eucaine Hydrochloride A. $C_{19}H_{27}NO_4 \cdot HCl + H_2O$.—It is a white, neutral, crystalline powder, soluble in ten parts of cold water,—i.e., about 9 per cent.

Eucaine Hydrochloride B ($C_{15}H_{21}NO_2 \cdot HCl$) is a white, neutral, crystalline powder, soluble in from 27 to 28 parts of cold water,—i.e., to the amount of from 3 to 4 per cent. at the ordinary temperature of the room. To make more concentrated solutions it must be slightly warmed. Such concentrated solutions remain perfectly clear quite long enough for the completion of an operation. If precipitation occurs after prolonged standing the solution may be clarified by heat.

Eucaine is affirmed to be in toxic dose a spinal cord depressant and a direct muscle poison, killing by its action upon the cardiac muscle. It is used solely as a local anæsthetic, less powerful than cocaine, but also much less toxic and not causing a primary constriction or a secondary dilatation of the local blood vessels, as does cocaine.

The 3 to 5 per cent. solution will rapidly and completely anesthetize the cornea without dilating the pupil or paralyzing the pupillary reflexes. The concentrations and dosage of the solutions generally recommended are as follows.

In ophthalmology, 2 per cent., applied by instillation.

In the urethra and bladder, 2 per cent. up to 60 Cc. (2 ounces) in amount.

In the nose, throat, and pharynx, 5 to 10 per cent., by spray or brush.

On mucose and wounds, 5 to 10 per cent., as much as required.

In dentistry, 2 to 5 per cent., amount 1 Cc. (15 minims).

For infiltration-anæsthesia:

(a) After Schleich, 1:1000 to 1 per cent., as much as required.

(b) After Réclus, 2 per cent., as much as required.

(c) After Braun, 1:1000 up to 0.3 gramme ($\frac{1}{2}$ grains).

For regional analgesia after Braun, 1 per cent. up to 0.15 gramme ($\frac{1}{4}$ grains).

The influence of eucaine upon the general system is so slight that fifteen grains (1 Gm.) of it have been injected hypodermically (G. W. Spencer) without the production of any marked symptoms. It may prove of value in *gastrodynia* or *vomiting*. The maximum dose is said to be three grains (0.2 Gm.).

Eucalyptus Manna. *Australian Manna.*—This substance exudes during the summer months from punctures made in the bark and leaves of the Australian tree *Eucalyptus mannifera*, (*E. viminalis*, Labill.). It occurs in small round opaque masses, and is said medicinally to resemble ordinary manna.

Eucasin. *Ammonium Caseinate, Casein-ammonium.*—This compound is obtained by passing ammonia gas over casein. It is a grayish-white powder, having an odor somewhat like buttermilk, readily soluble in hot water. It has been brought forward by Salkowski as a very easily digested food. It may be given in broths or with cocoa, and, according to Feustell (*D. M. W.*, xxii. 1896),

is a valuable food in cases of great failure of digestion. From thirty to forty grains of eucasin correspond to twenty-four to thirty-two grains of albumin.

Eugrenine.—A local anæsthetic in the form of capsules each containing one-twelfth of a grain of eucaine and one four-thousandth of a grain of adrenalin hydrochloride. Used especially in dentistry.

Eugallol. Pyrogallol-mono-acetate. $C_6H_3(OH)_3CH_3CO_2$.—A thick transparent mass, brownish yellow in color, soluble in water and in its own weight of acetone. A 33 per cent. acetone solution is used externally as a substitute for pyrogallol in the treatment of psoriasis.

Eugenia Chequen. Molina. (*Myrtus Chequen*, Spreng.) *Cheken. Chekan. Chequen. Arrayan.* (Fam. Myrtaceæ).—The leaves of this Chilean plant have entered commerce under the name of *Chekan leaves*. Weiss (*P. J.*, 188, 246) has found in them,—1, *chekenon*, $C_{40}H_{44}O_8$, a crystalline body; 2, *chekenin*, $C_{12}H_{11}O_3$, in yellowish rhombic tables; 3, *chekenetin*, $C_{11}H_7O_6 + H_2O$, in olive-colored crystals; 4, *cheken-bitter*, an amorphous, very soluble bitter substance. (See also *P. J.*, 1889, 782.) *Chekan leaves* are reported by W. Murrell to be useful in chronic bronchitis. For an additional account of them and their properties, see *P. J.*, ix. 653; and *Newer Materia Medica*. The leaves are used in their native country as a remedy in chronic respiratory catarrh, and have been strongly recommended by Murrell and others in chronic bronchitis. Their virtues appear to reside in the tannin, and especially in the volatile oil that they contain. Fritz Wein (*A. Pharm.*, 1888, 665) examined cheken leaves proximately; he found a volatile oil and three crystalline bodies, *chekenon*, *chekenin*, and *chekenetin*, and an amorphous bitter principle. The dose of the fluid-extract is from one to three fluidrachms (3.9–11.6 Cc.).

Eugenia Jambolana, Lam. *Jambul. Jamboo. Rose Apple. Java Plum.*—This is a large tree belonging to the Myrtaceæ, growing in East India and also in Queensland; well known on account of its popular edible fruit. Jambul bark is a dense, hard bark, of a pinkish-brown or reddish-brown color, with a whitish-gray mottled epidermis adherent to portions of its outer surface; the inner surface is of a somewhat silky lustre, frequently coarsely marked by waving lines or ridges; the fresh fracture varies from pinkish or purplish to fawn color, sometimes distinctly but shortly fibrous, more commonly absolutely abrupt; the thickness of the bark varies from a quarter of an inch to nearly one inch. The taste is somewhat bitter, astringent, after a time distinctly pungent. The seeds are grayish black or blackish gray, being abruptly truncated at the base, above rounded or dome-shaped. They are about a third of an inch in diameter and three-eighths of an inch long; so hard and dense that they cannot be chewed, and are almost tasteless. The analysis of the seeds by Thomas Christy yields the following results. Essential oil, a trace; chlorophyll and fat, 0.37; resin soluble in alcohol and ether, 0.30; gallic acid, 1.65; albumen, 1.25; colored extractive soluble in water, 2.70; moisture, 10.00; insoluble resin, 83.73.

In the experiments made by Thomas Christy of London (*P. J.*, 1888), it was found that when sufficient of diastasic matter was mixed with fifty grains of starch to convert 45 per cent. of the latter in fifty minutes into sugar, the

addition of twenty-five grains of powdered jambul seeds reduced the conversion of the starch to 12 per cent. We have no knowledge of the effect of jambul or its active properties upon the general organization, but Binz (*Verhandl. der Kongr. für Innere Med.*, Wiesbaden, 1886) found that when dogs were made diabetic by the administration of phlorizin, according to the method of von Mering, the exhibition of jambul reduced the excretion of sugar from 50 to 90 per cent. without the production of any evidences of poisoning by the jambul. In India, jambul has long been used as a stomachic astringent and carminative in *diarrhœa*, and also in the treatment of *diabetes*. The first therapeutic trials in Europe appear to have been made by Clacius, who found that the drug notably reduced the excretion of sugar in diabetic patients. The practice has been largely followed, and there would seem to be no doubt that in occasional cases of glycosuria jambul does good. H. C. Wood has seen the sugar of the urine entirely disappear under its use. No cases of poisoning or of disagreeable results from it have been reported.

Nevertheless jambul has failed to establish itself as a practical medicament. It may be that this has been due to the use of too small doses. The fluidextract is the best preparation and the beginning dose of it, recommended in previous editions of the *U. S. D.*, was ten minims (0.6 Cc.); but according to von Noorden (*Deutsche Praxis*, 1901) half a fluidounce (15 Cc.) of the fluidextract should be taken in eight fluidounces (240 Cc.) of hot water, one hour before breakfast and late in the evening.

Eugenolform. *Eugenol carbinol sodium*, forms colorless crystals fusing at 160° C. (320° F.), readily soluble in water, difficultly soluble in alcohol. Is used as a bactericide for disinfection of the intestines in cases of *typhoid fever*, *cholera*, etc.

Eugenol Acetamide. $C_{10}H_{11}O_2(CO.CH_2NH_2)$. This substance occurs in shining scales or needles, soluble in alcohol and water, melting at 110° C. (230° F.). According to Merck, it is a local anæsthetic and at the same time antiseptic.

Eugenol Iodide. *Iodo-eugenol.* $C_6H_5I(C_8H_5)(OCH_3)OH$.—A yellowish, inodorless, insoluble powder obtained by acting on eugenol-sodium with iodine. It is used as an antiseptic, and said to resemble aristol.

Euguform.—*Acetylied methylene diguacicol* is obtained by the action of formaldehyde upon guaiacol and subsequent acetylation. It is a white, almost odorless, dust-like and amorphous powder, insoluble in water. It has been recommended by Ciesielski as a cheap substitute for orthoform, as a dusting powder or in the form of a 2 to 10 per cent. ointment. (*Derm. Cb.*, 1901, No. 6.)

Eumenol is a liquid preparation of the Chinese root *Tang-kui*, one of the Araliaceæ. It has been recommended for the relief of *dysmenorrhœa* by Langes (*Th. M.*, 1901, 363) and others.

Euphorbia. *Wild Ipecac. Wild Hippo. Euphorbe.* Fr. *Wolfsmilch*, G.—The genus *Euphorbia* (Fam. Euphorbiaceæ) contains numerous species, having the common property of yielding a milky juice. They are herbaceous or shrubby, with or without leaves, and the leafless species, which are chiefly confined to the African deserts, have fleshy, naked, or spiny stems, like those of the cactus. They nearly all afford products which act powerfully as emetics and cathartics, and in

overdoses occasion dangerous if not fatal prostration, with symptoms of inflammation of the gastro-intestinal mucous membrane. Their milky juice, which concretes on exposure, usually possesses these properties in a high degree, and, in addition, that of powerfully irritating the skin when applied to it. The U. S. Pharmacopœia formerly recognized the indigenous species *E. corollata*, L., and *E. Ipecacuanha*, L. In a full dose the root of *E. corollata*, L., operates actively and with sufficient certainty as an emetic, producing ordinarily several discharges from the stomach, and sometimes acting with considerable energy upon the bowels. In quantities insufficient to cause vomiting, it excites nausea, almost always followed by brisk purging. In still smaller doses it is diaphoretic and expectorant. It is, however, too harsh and uncertain in its action for practical use, and has passed entirely out of vogue. The dose of the dried root as an emetic is from ten to twenty grains (0.65–1.3 Gm.), as a cathartic from three to ten grains (0.2–0.65 Gm.). The recent root, bruised and applied to the skin, produces vesication. C. Petzolt found in the root of *E. Ipecacuanha* fixed oil, resin, starch, glucose, and various salts. The resinous matter was a dark mass, of a taste slight at first but after a time nauseous and pungent, readily dissolved by alcohol, but insoluble in ether and petroleum benzin, and, when swallowed, producing in half grain (0.032 Gm.) doses watery stools, and in one and a half or two grain (0.096 or 0.13 Gm.) doses nausea and vomiting. It gave no evidence of the presence of an alkaloid. (*A. J. P.*, 1873, 255.) The medicinal properties of *E. Ipecacuanha* resemble those of *E. corollata*, though the former is said to be somewhat milder. The indigenous *E. Preslii*, Guss. (*E. hypericifolia*, A. Gray), and *E. maculata*, L., are said by Zollicoffer to be a valuable remedy in dysentery, diarrhœa, menorrhagia, and leucorrhœa. (See 16th ed. U. S. D., also *A. J. M. S.*, xi.) B. J. D. Irwin, U. S. A., states that, under the name of *gollindrineria*, the native Mexican uses the *Euphorbia prostrata*, Ait., in New Mexico and Arizona as a remedy for snake bites. (*Am. J. M. S.*, 1861.) In Chili the juice of *Euphorbia portulacoides*, L. (*E. chilensis*, C. Gay), is said to be used as a drastic purgative. (*A. J. P.*, 1866, 102.) The juice of *Euphorbia Drummondii*, Boiss., is said in Australia to kill annually a great many sheep and cattle, and in 1886 John Reid (*Australasian Med. Gaz.*, No. 61) announced the discovery in it of a new anæsthetic alkaloid, *drummine*, which he obtained in colorless crystals almost insoluble in ether, but freely soluble in chloroform and in water. The report of Alexander Osgden (*B. M. J.*, Feb. 1887) throws, however, very grave doubts upon the anæsthetic power of this new alkaloid. The *E. ocellata*, Durand and Hilgard, of the Pacific coast is used as an antidote for snake bites, and is said to contain 2.82 per cent. of resin, besides gallo-tannic acid, while *Euphorbia cremocarpus*, Auct., of the same region is employed for the purpose of catching fish in still pools and streams, and is said to contain a volatile oil, besides acid and resins. (See *Proc. California Coll. Pharm.*, 1885.) The oil of *E. Lathyris*, L., is stated to physiologically resemble croton oil. (*Proc. A. Ph. A.*, xxvi. 305.)

The *E. heterodowa*, Muell.-Arg., *alvelox* or *avelox*, a Brazilian species, has been used with asserted extraordinary advantage against cancerous and syphilitic ulcers. It is a powerful irritant,

and even mild caustic. The milky juice, preserved with salicylic acid, or a resin obtained by precipitating with water is employed. The ointment of the resin may be made 3 parts in 100 with vaseline.

Euphorbia pilulifera, L.—A prostrate or ascending branched annual, found in almost all tropical countries; it is furnished with leaves which are opposite, shortly stalked, ovate to ovate-lanceolate or oblong, from three-quarter inch to one and a half inches long, denticulate, very oblique and narrow below, or with a semi-cordate base. Stipules minute, linear, inserted on a transverse raised line. The flower-heads are minute, numerous, crowded in head-like cymes, globular, and are borne on a short stalk in one axil only of each pair of opposite leaves. The involucre is about one-third of a line long, small, entire, and without petal-like appendages. According to De Candolle, the seeds are reddish, acutely oblong, four-sided, and transversely wrinkled, the ridges uniting irregularly. It is to be distinguished from *E. parviflora* (L.), which is sometimes substituted for it, by the flower-head of the latter having but few flowers, by the glands of the involucre being furnished with a white, obovate-orbicular appendage, and seeds which are minutely papillose. Levison found in it (*A. J. P.*, 1885, 147) several glucoside resins, wax, and volatile matter.

A physiological study of *Euphorbia pilulifera* led A. Marsset (*T. G.*, 1885) to the conclusion that the active principle acts directly upon the heart and respiration; that it is not an irritant to the skin, but in large dose it is to the gastric mucous membrane. It has been used by Dujardin-Beaumetz and a number of other clinicians with asserted excellent results in the treatment of asthma and asthmatic bronchitis, also in chronic bronchitis, and in advanced or subacute bronchitis. The best preparation is the fluidextract, the dose of which is from a half to one fluidrachm (1.8–3.75 Cc.) three or four times a day.

Euphorbium. *Euphorbium*, P. G. *Euphorbe*, *Gomme-résine d'Euphorbe*, Fr. *Euphorbiumharz*, G.—The concrete resinous juice of one or more species of *Euphorbia* (Fam. Euphorbiaceæ); but its precise source is uncertain. It has been ascribed to *E. resinifera*, Berg. (*E. officinalis*, Jack.), growing in the north of Africa and at the Cape of Good Hope, *E. canariensis*, L., a native of the Canary Islands and Western Africa, and *E. antiquorum* (L?), inhabiting Egypt, Arabia, and the East Indies, and supposed to be the plant from which the ancients derived this resinous product. These species of *Euphorbia* bear some resemblance in form to a cactus, having leafless, jointed, angular stems, divided into branches of a similar structure, and furnished with double prickles at the angles. When wounded they yield an acrid milky juice, which concretes on the surface, and constitutes the euphorbium of commerce.

Euphorbium occurs in the shape of tears, or in oblong or roundish masses, about the size of a pea or larger, often forked, and perforated with one or two small conical holes, produced by the prickles of the plant, around which the juice has concentered, and which sometimes remain in the holes. The masses are occasionally large and mixed with impurities. The surface is dull and smooth, bearing some resemblance to that of tragacanth; the consistence somewhat friable, the color light yellowish or reddish; the odor scarcely perceptible; the

taste at first slight, but afterwards excessively acid and burning. The color of the powder is yellowish. The sp. gr. of euphorbium is 1.124. Triturated with water it renders the liquid milky and is partially dissolved. Alcohol dissolves a larger portion, forming a yellowish tincture, which becomes milky on the addition of water. Its constituents, according to Pelletier, are resin, wax, calcium malate, potassium malate, lignin, bassorin, volatile oil, and water. It contains no soluble gum. The most abundant constituent is resin, and the remainder consists chiefly of wax and calcium malate. The resin is excessively acid, is soluble in alcohol, and, when exposed to heat, melts, takes fire, and burns with a brilliant flame, diffusing an agreeable odor. According to Flückiger, it has the formula $C_{10}H_{16}O_2$. Flückiger also found a substance analogous to lactucen, which he names *euphorbon*. It is neutral, fusible above $106^\circ C.$ ($222.8^\circ F.$), readily dissolved by boiling alcohol, and soluble in ether, petroleum benzin, amyl alcohol, chloroform, acetone, and glacial acetic acid. From its solution in ether and petroleum benzin it separates on spontaneous evaporation, in feathery needles. Its solution in sulphuric acid, spread on a plate, is colored violet by nitric acid. Its composition is $C_{13}H_{22}O$. While the acid resin constitutes 38 per cent. of euphorbium, 22 per cent. of euphorbon is found in it (A. J. P., 1868, 393; from S. W. P.). Hesse (Ann. Ch. Ph., xcii. 182) has prepared pure euphorbon, and gives it the formula $C_{15}H_{24}O$, fusing point from 113° – $114^\circ C.$ (235.4° to $237.2^\circ F.$), making it isomeric with lactucon. It is levorotatory.

Euphorbium taken internally is a very irritant emetic and cathartic, and in large doses acts as a violent gastro-intestinal irritant poison. In consequence of the severity of its action, its internal use has been entirely abandoned. Applied to the mucous membrane of the nostrils, it excites violent irritation, attended by incessant sneezing and sometimes bloody discharges. Persons who powder it are under the necessity of guarding their eyes, nostrils, and mouth against the fine dust which rises. Largely diluted with wheat flour or starch, it has been used as an errhine in *amaurosis* and *deafness*. Externally applied, it inflames the skin, often producing vesication. It enters into some epispastic preparations, and is especially employed in veterinary practice as a vesicant.

Euphrasia. *E. officinalis*, L. *Eyebright*. *Euphrasia*, Fr. *Augentrost*, G. (Fam. Scrophulariaceae.)—A small annual plant, native of Europe, without odor, and of a bitterish, astringent taste. Enz (Viertel. f. Prakt. Pharm., viii. 175) obtained a little volatile oil, an acid and bitter principle, mannite and glucose, and a tannic acid, the lead salt of which showed on analysis the formula $C_{32}H_{20}O_{17} \cdot 3PbO$ and had a bright green color. It was formerly used in *toothache*. G. M. Garland (A. J. P., 1890) states that ten minims (0.6 Cc.) of a concentrated tincture every two hours is a specific in acute *nasal catarrh*.

Euphthalmine Hydrochloride.—This is the mandelic acid derivative of Eucaine B, just as homatropine is the mandelic acid derivative of the base tropine. A permanent snow-white crystalline powder, very soluble in water and soluble in about two parts of boiling absolute alcohol, separating again on addition of ether in crystalline aggregates. The salt is anhydrous; it melts at from 183° – $184^\circ C.$ (361.4° – $363.2^\circ F.$) and begins to run together at $181^\circ C.$ ($357.8^\circ F.$). The sal-

icylate, $C_{17}H_{25}O_3N, C_6H_4(OH)COOH$, prepared by mixing ether solutions of the base and of salicylic acid, and recrystallizing from absolute alcohol and ether, melts at from 115° – $116^\circ C.$ (239° – $240.8^\circ F.$), and is very readily soluble in water. The hydrochloride of the unstable *n*-methyl-vinyl-diacetone-alkamine is a colorless crystalline powder, freely soluble in water, to which Treutler and Vossius have called attention as a powerful local mydriatic. From two to three drops of a 2 per cent. solution will produce in from twenty to thirty minutes pronounced mydriasis, which disappears after two or three hours (seven hours, Winselmann) and is not accompanied by pain or other unpleasant secondary effects. There is no irritation of the cornea, or local anæsthesia, and accommodation is said to be less affected than with the mydriatics in common use. (Ther. Woch., 1897; Ber. d. Chem. Ges., xxxi. 665.)

Eupyrine. *Para-phenetidine-vanillin-ethyl-carbonate*. $C_6H_4 \begin{cases} \text{OC}_2H_5 \\ \text{N}=\text{CH} \cdot C_6H_5 \end{cases} \begin{cases} \text{O} \cdot \text{COOC}_2H_5 \\ \text{OCH}_3 \end{cases}$

This substance occurs in pale greenish-yellow, tasteless needles, with a vanillin odor, melting at 87° to $88^\circ C.$ (188.6° – $190.4^\circ F.$), sparingly soluble in water, freely so in alcohol, ether, and chloroform. It forms salts by combination with a few acids. It has been brought forward by Overlach (Cb. I. M., xxi. 1900) as an antipyretic, who found that half an ounce of it causes no serious symptoms in dogs. He claims that it produces a gradual but marked fall of the temperature, accompanied by a sense of euphoria rather than of depression. In neuralgia he found that it was without influence. Porges has confirmed the statements of Overlach. The remedy is stated to be of special value in the young and the aged. Dose, twenty to thirty grains (1.3–2.0 Gm.).

Euquinine. *Quinine Ethyl Carbonic Ether*. $CO < \begin{matrix} \text{O} \cdot \text{C}_2H_5 \\ \text{O} \cdot \text{C}_{20}H_{23}N_3O \end{matrix}$. Euquinine is made by the action of chloro-carbonic ethyl-ether on quinine. It occurs in the form of fine needle-like white crystals, melts at $95^\circ C.$ ($203^\circ F.$), is scarcely soluble in water, but easily so in alcohol, ether, and chloroform. It forms crystalline salts. A solution in sulphuric or nitric acid fluoresces with a blue color like quinine. The thalleioquin reaction of euquinine is the same as that of quinine, but there is no herapathite reaction. The euquinine hydrochloride dissolves readily in water, the sulphate much less easily, while the tannate is almost insoluble.

It has been alleged that it is possible by the use of euquinine to obtain the beneficial effects of quinine without unpleasant accompaniments of cerebral congestion and irritation, although tininitus aurium is produced. It is absorbed rapidly, and according to Panegrosso and Gammarelli its elimination by the kidneys can be demonstrated within half an hour after its ingestion, and is completed in about forty-eight hours. It has been suggested, but not demonstrated, that within the body it is decomposed, quinine being re-formed from it. Euquinine has been employed with asserted satisfactory results by C. von Noorden (Cb. I. M., 1896) in *pneumonia*, *pleurisy*, and various other acute diseases, as a substitute for quinine, and the results have been confirmed by Goliner (Allge. Med. Central-Zeitung, 1897) and by Overlach (D. M. Ztg., 1897), while, following Panegrosso (Gaz. degli ospedali, Oct. 1897),

numerous physicians have tried it in malaria; A. Celli and A. Mori, experimenting in the Pontine marshes and other malarial districts of Middle Italy, have found that in doses of ten grains (0.65 Gm.) a day it is very effective in preventing the contraction of disease. (*Cb. B.*, vol. xxix.) In doses of twenty to thirty grains (1.3–2.0 Gm.) it has been found effective in intermittent fevers. As a tonic Overlach found it useful in small doses in chlorosis and anemia, and this has been confirmed by other observers. Von Noorden, Castle, Niedermayer, and others commend it in whooping cough. It is so far tasteless that it may be administered in milk or syrup and is usually very well borne by the stomach, so that it is especially useful in the treatment of children. The necessary doses are larger than those of quinine; in ordinary acute diseases thirty grains (2 Gm.) may be given daily; in malaria forty grains (2.6 Gm.).

Euresol is monoacetyl resorcinol, $C_6H_4(OH)OCOCH_3$. A viscid honey-like liquid, boiling at $283^\circ C.$ ($541.4^\circ F.$). It is made by heating resorcinol with glacial acetic acid.

Eurobin.—Triacetyl chrysarobin is used as a substitute for chrysarobin; it is soluble in chloroform, acetone, and ether, insoluble in water. *Lenirobin*, the tetracetyl derivative, is similarly used.

Europhen. *Di-isobutyl-ortho-cresol-iodide*. $(C_4H_9)(CH_3)C_6H_3O$ HI.—This is a yellow amorphous powder, of a specific aromatic odor, which has been proposed as a substitute for iodoform. It is asserted that it is five times lighter than iodoform, and can be used in much larger bulk; that it is equally efficacious with iodoform; also that it is decomposed more slowly than iodoform, and is, therefore, less poisonous. (See *Ph. Ztg.*, July, 1891; also *Th. M.*, July, 1891.) Europhen is made by the action of iodine upon isobutylortho-cresol in alkaline solution. It occurs as a fine, soft, amorphous powder, light yellow, tasteless, and having but a faint odor. It is soluble in ether, chloroform, collodion, alcohol, and fixed oils; insoluble in water and glycerin; melting at $110^\circ C.$ ($230^\circ F.$). Its solution undergoes decomposition when exposed to light or heat.

Europhen contains about 28.1 per cent. of iodine, which element is slowly liberated from its alcoholic and ethereal solutions. It is incompatible with metallic oxides and mercurial salts, and undergoes slight change in the presence of organic matter. Taken internally it is said to pass out in great part from the alimentary canal with the feces unchanged, though some absorption takes place. It is asserted that it is non-toxic, two or three drachms (7.7–11.6 Gm.) having been given to dogs and fifteen grains (1 Gm.) to human beings without effect. As a microbicide it is affirmed to be about equivalent to iodoform. (*Revue Méd. de l'Est*, Feb. 1892.)

It has been used by a number of clinicians with asserted good results as a local application in chancres, syphilitic ulcers, burns, psoriasis, eczema, lupus, and various skin diseases. It is usually applied in an ointment varying in strength, according to the individual cases, from 1 to 10 per cent. It has also been employed in rhinitis, laryngeal tuberculosis, and other inflammatory disorders of the preliminary air-passages. Internally it has been used, especially hypodermically, dissolved in oil, in constitutional syphilis, with not very encouraging results. Dose, one-half to one and one-half grains (0.032–0.096 Gm.).

Under the name of *europhe-aristol* a mixture of europhen and aristol has been marketed.

Eurybin.—A glucoside obtained from a New Zealand plant, *Eurybia moschata*. (*Merck's Bericht*, 1893, 12.)

Evodia.—Several species of this rutaceous genus are stated to have medicinal properties. *E. febrifuga* of Brazil is astringent and tonic, *E. glauca* of Japan contains berberine, while *E. longifolia* of the Feejee Islands is used to prevent abortion.

Exalgine. *Methylacetanilide*. $C_6H_5N(CH_3)COCH_3$ or $C_9H_{11}NO$.—This substance, which was discovered by Brignonnet, is one of the three isomeric methyl derivatives of acetanilide (*O. R. A. S.*, cviii. 571), and is made by warming together monomethylaniline and acetylchloride. It occurs in needles, or in long tablet-like crystals, according as it is obtained by crystallization or from the mass after fusion. It is sparingly soluble in cold water, quite soluble in hot water, and readily soluble in very dilute alcohol, or in water to which a small amount of alcohol has been added; it fuses at $101^\circ C.$, and boils between 240° and $250^\circ C.$ without decomposition. The hot aqueous solution is said by Upton to retain most of its exalgine on cooling.

According to Brignonnet, hypodermic injections of exalgine produce in the lower animals violent epileptiform convulsions, profuse salivation, cyanosis, disturbance of breathing, fall of temperature, and alteration of the blood, which becomes dark prune-colored and contains an abundance of methæmoglobin. The muscles at the seat of the injection are said to be locally paralyzed, and although small doses increase slightly the blood pressure, after the toxic dose the pressure suddenly falls. The urine does not become albuminous or bloody. When given to man in full, non-poisonous doses, it produces some slight amblyopia, vertigo accompanied in some patients by vomiting, tinnitus aurium, headache, drowsiness, and vasomotor disturbances, such as sweating. After large doses, cyanosis is pronounced, but no eruption upon the surface of the skin seems as yet to have been noticed. After toxic doses dyspnea, cyanosis, dilated pupils, paresis, heart failure and convulsions have been noted, but no fatal result has been recorded; in a boy fourteen years old two doses of 3 grains each produced most alarming symptoms.

Therapeutically, exalgine seems to be an antipyretic, but it has been used almost exclusively as an analgesic and antispasmodic. According to Moncorvo, it is very well borne in children; he has used it extensively in chorea, polyuria, and for the relief of pain. He believes that its analgesic effect is at least five times as strong as that of antipyrine; his dose, to a child five years old, is one and a half grains (0.096 Gm.). Dose, for an adult, three to five grains (0.2 to 0.32 Gm.), not more than twelve grains to be given in twenty-four hours.

Fabiana. *Fabiana imbricata*, Ruiz and Pavon. *Pichi*. (Fam. Solanaceæ.)—This is a shrub growing in Chili and the Argentine Republic, attaining the height of about six feet. The appearance of the plant is almost that of a conifer, but it has white flowers. The wood is uniformly yellowish, hard, heavy, and very fine grained. The thin bark is light gray, minutely roughened by small, sharp, longitudinal ridges, and minute gland-like protuberances, which exhibit under the lens a peculiar resinous lustre. For microscopic structure, see *Proc. A. Ph. A.*, 1889.

A. B. Lyons first obtained a fluorescent body resembling æsculin, a neutral crystalline principle, some volatile oil, resin, and apparently traces of an alkaloid. (A. J. P., 1886, 65.) Henry Trimble and J. M. Schroeter (A. J. P., 1889, 407) considered the crystalline principle to be a resin, and gave it the formula $(C_{18}H_{31}O_2)_x$. H. Kunz-Krause (A. J. P., 1900, p. 80) more recently made a full study of pichi and found a tannin which he named *fabiana-tannoid*, a fluorescent substance proven to be *chrysotropic acid* (β -methyl æsculetin), $C_9H_5(CH_3)O_4$, while no alkaloids are present, the sole basic principle being choline. The volatile oil he names *fabianol* and gives it the formula $C_{54}H_{90}O_2$. The resin he calls *fabiana-resin* and gives to it the formula $(C_{18}H_{30}O_2)_3$. The resin appears in microscopical crystals, melting at 280° C. The tannin proved to be like caffeotannic acid, which Kunz-Krause had previously shown to be *glycosyl-dioxy-cinnamic acid*.

Pichi appears to be a terebinthinate diuretic, to which also are attributed tonic and cholagogue properties. It has been used to a considerable extent in the treatment of *acute and chronic vesical catarrh*, giving especially favorable results in cases in which the urinary irritation is kept up by *gravel*. It is said even to calm the irritability and aid in the expulsion of *renal, urethral, or cystic calculi*. It has been further recommended in the treatment of *jaundice and dyspepsia*, with lack of biliary secretion. It is somewhat irritating, and is usually said to be contra-indicated by the existence of organic disease of the kidneys; but cases have been reported in which *renal hemorrhage* connected with Bright's disease has been greatly benefited by the remedy. It has also been employed in *gonorrhœa* and in *gonorrhœal prostatitis*. The solid extract may be used in the dose of from two to ten grains (0.13–0.65 Gm.); the fluidextract, in the dose of from ten to forty minims (0.6–2.5 Cc.). It is probable that the resinoid precipitate, made from a strong tincture by means of water, would be the best preparation of the drug. The fluidextract does not mix with water unless the solution be made alkaline. It may be administered in capsules.

Fanghi di Sclofani.—This is a light yellowish fine powder of volcanic origin, consisting chiefly of sulphur and small quantities of iron, manganese, calcium, etc., the sulphur being in an exceedingly fine powder. It is highly praised by Otto v. Fleischl as a remedy in *acne rosacea*. Two or three grains (0.13 or 0.2 Gm.) of the powder are mixed with a teaspoonful (4 Cc.) of water and the opaque mixture applied with the finger on going to bed and allowed to dry on the part.

Ferissol.—This is a substance said to be derived from cinnamic acid and guaiacol which occurs as a very soluble powder and has been used in *tuberculous diseases* intermuscularly in 10 per cent. solutions, fifteen minims (0.9 Cc.) per dose, increased to forty-five minims (2.8 Cc.). The internal dose is fifteen grains (1 Gm.).

Ferralbumose.—This is made by treating finely cut meat, freed from fat, with an artificial gastric juice, freeing the solution from albumin, neutralizing it with sodium carbonate, filtering and evaporating to dryness, *in vacuo*. A 10 per cent. solution of this *albumose* is precipitated by the addition of a 10 per cent. solution of ferric chloride and the precipitate dried, powdered and sifted.

Ferratin.—This is a light brown powder containing from 6 to 8 per cent. of iron in a form soluble in alkaline liquids. It is an albuminous

compound, originally prepared by Schmiedeberg from the liver of the hog, and believed to be the natural compound of iron as it exists in the system, and therefore of especial value in therapeutics. It is now made by the reaction of the albumin with a double tartrate of iron and an alkali. It is almost insoluble in water, soluble in alkalies, and contains 7 per cent. of iron in organic compounds. A solution of ferratin has also been put upon the market under the name of *ferratose*. Ferratin may be given in doses of from three to five grains (0.2–0.32 Gm.) three times a day. It appears to be capable of acting as a chalybeate, but there is no sufficient reason for believing it to be superior to the older preparations of iron.

Ferratogen. Ferric Nucleine.—This substance is obtained by the cultivation of yeast on a ferruginous nutritive medium and subsequently extracted. It occurs as a grayish-white or yellow powder, insoluble in water and gastric juice, but believed to be dissolved by pancreatic fluid. It has been recommended by Cloetta in *chlorosis* when the stomach is delicate. Dose, five to ten grains (0.32–0.65 Gm.).

Ferric Albuminate. Ferri Albuminas.—This preparation has come into some prominence, more particularly in Europe, on account of its asserted advantages over various other compounds of iron, Démarquay, Chrisnard, and others recommending its employment in *chlorosis* and *anæmia*, as being very readily absorbed. Friesse, Kobligk, Bernbeck, Biel, Holdermann, Nierek, Donitz, and Hager have each proposed methods for preparing either the solution or dry salt. C. L. Diehl, however, after a careful review of the processes of these investigators, offers the following: 4 troyounces of white of eggs are diluted with 8 fluidounces of water; 65 minims of official solution of ferric chloride diluted with 4 fluidounces of water are added, and the solution filtered. The filtrate is now mixed with 10 fluidounces of a saturated solution of sodium chloride, the precipitate collected on a wet muslin strainer, washed with a mixture of 1 volume of the saturated solution of sodium chloride and 3 volumes of water, until the washings give but a faint reaction for iron. The washed ferric albuminate is, after draining, powerfully pressed to get it as dry as possible, and then exposed to a dry atmosphere, and finally powdered. This salt contains the equivalent of 5 per cent. of ferric oxide, or 10 per cent. of ferric chloride. For other processes, see A. J. P., 1880, 177. As thus obtained, ferric albuminate is a cinnamon-brown powder, having a slight taste of common salt (due to the presence of a small quantity), soluble in water, particularly if slightly acidulated with hydrochloric acid. It is best administered in doses of from twenty to thirty grains (1.3–2.0 Gm.) in simple aqueous solution, which should be freshly prepared. It may also be given in the form of a pill, either alone or combined with strychnine, quinine, etc. For method of preparing iron and potassium albuminate, and iron and sodium albuminate, see 16th ed. U. S. D.

Ferric Arsenio-Citrate (Ammoniated).—This compound under the name of Ferr-Arsenio-Citras Ammoniatum has been highly commended by Valvassori and Peroni (see M. R., 1900) for the hypodermic treatment of *malaria*, especially in children. It is given in doses of three-fifths of a grain (0.036 Gm.) in sterilized water, injected at intervals of two or three days.

Ferric Benzoate. Ferri Benzoas. Ferrum Benzoicum. Eisenbenzoat, Ferribenzoat, G. Fe₂

$(C_7H_5O_2)_3(OH)_3 + 6H_2O$.—This is made by precipitating a solution of ammonium benzoate with a diluted solution of ferric chloride. The precipitate, after being washed, is dried at a temperature not above 30° C. (86° F.), protected from light. A brownish-red, odorless, tasteless, powder insoluble in water. When freshly prepared it is soluble in cod liver oil.

Ferric Glycerophosphate. *Ferri Glycerophosphas. Ferrum Glycerinophosphoricum. Iron Glycerophosphate. Glycerinphosphorsäures Eisen, G.* $Fe_2[C_3H_5(OH)_2PO_4]_3$.—This is made by dissolving freshly precipitated ferric hydroxide in glycerophosphoric acid, evaporating the solution *in vacuo* and sealing it upon glass plates. It is in the form of yellow scales, soluble in water and diluted alcohol. The salt is used as a tonic and nervine in doses of from five to ten grains (0.32 to 0.65 Gm.).

Ferric Iodate. *Ferri Iodas. Basic Ferric Iodate.* $2Fe_2(IO_3)_6 \cdot Fe_2O_3 \cdot 24H_2O$.—This has been proposed as a substitute for the iodide by Cameron. (*Dublin Q. J.*, 1869, 354.) It is prepared by precipitating five fluidrachms of the strong solution of iron perchloride (B. Ph.) in four fluidounces of water with a solution of one ounce of potassium iodate in ten ounces of water. It is said to be nearly tasteless, and not to injure the teeth. *Dose*, from two to five grains (0.13–0.32 Gm.).

Ferric Oxide, Magnetic. *Ferri Oxidum Magneticum. Magnetic Iron Oxide. Martial Ethiops. Ferrum Oxydatum Magneticum. Oxydum Ferroso-Ferricum. Black Iron Oxide. Oxyde de Fer noir (magnétique), Oxyde ferroso-ferrique, Fr. Magneteisen, Eisenoxyd-Oxydul, G.*

"Take of Solution of Persulphate of Iron five and a half fluid ounces [Imperial measure]; Sulphate of Iron two ounces [avoirdupois]; Solution of Soda four pints [Imp. meas.]; Distilled Water a sufficiency. Dissolve the Sulphate of Iron in two pints [Imp. meas.] of the Water, and add to it the Solution of Persulphate of Iron, then mix this with the Solution of Soda, stirring them well together. Boil the mixture, let it stand for two hours, stirring it occasionally, then put it on a calico filter, and, when the liquid has drained away, wash the precipitate with Distilled Water, until what passes through the filter ceases to give a precipitate with chloride of barium. Lastly, dry the precipitate at a temperature not exceeding 120°." *Br.* 1867.

Though the object of this formula is the same as that of the Br. Pharmacopœia of 1864, the proceeding is different. The point aimed at is to get an iron oxide containing one molecule of ferrous oxide and one of ferric oxide.

Properties.—The artificial magnetic iron oxide is a brownish-black powder, without taste, and strongly magnetic. According to the former Br. Pharmacopœia, it consists of a 3-4 iron oxide, Fe_3O_4 , with about 20 per cent. of water of hydration, and a portion of iron peroxide (sesquioxide). It dissolves without effervescence in hydrochloric acid diluted with half its bulk of water, and the solution gives a blue precipitate both with the potassium ferrocyanide and the potassium ferricyanide, showing the presence of ferrous and ferric oxide. *Dose*, from five to twenty grains (0.32–1.3 Gm.).

Scales of iron (ferri squamæ) were formerly official with the Dublin College under the name of black oxide. They were prepared from the scales found at the blacksmith's anvil, by washing them with water, separating them from impurities by

means of a magnet, and reducing them to a fine powder. They are of variable composition, being mixtures of the two oxides of iron with metallic iron.

Ferric Saccharate. *Saccharate de Fer, Saccharure d'Oxyde de Fer soluble, Fr. Eisenzucker, Lösliches Eisenoxyd, G.*—The *Ferrum Oxydatum Saccharatum* of the German Pharmacopœia is of importance as an antidote to arsenic. The process is as follows: Dilute 30 parts of solution of ferric chloride with 150 parts of water; add to this, little by little, a solution of 26 parts of crystallized sodium carbonate in 150 parts of water; wash the precipitate thoroughly with distilled water on a muslin strainer and press out the excess of water; add 5 parts of sugar and 15 parts of solution of sodium hydroxide, U. S. P. (8th Rev.); heat on a water bath until a clear solution is obtained. This is evaporated to dryness and enough sugar added to make 100 parts. (*See Arseni Trioxidum*, p. 197; *A. J. P.*, xlv. 559.)

Ferric Salicylate. *Ferri Salicylas. Ferrum Salicylicum. Ferrisalicylat, G.*—Made by adding sodium salicylate to a concentrated solution of ferric chloride. The violet colored precipitate, when washed and dried forms a brown mass or powder insoluble in water. It is sometimes used as a tonic and antirheumatic in doses of from three to ten grains (0.2 to 0.65 Gm.).

Ferric Succinate. *Ferri Succinas. Succinate of Iron.*—The precipitate obtained by adding ferric chloride to a solution of a succinate is a basic salt $(C_4H_4O_4)_2Fe_2(OH)_2$. This is yellowish in color, becoming darker on standing. Ferric succinate has been introduced as a remedy for *jaundice* resulting from obstruction of the biliary duct; also as a chalybeate. *Dose*, five grains (0.32 Gm.).

Ferric Tannate. *Ferri Tannas.*—This salt is prepared by dissolving 44 parts of precipitated ferric subcarbonate, moderately dried, in a boiling solution of 9 parts of pure tannic acid, evaporating the solution at the temperature of 80° C. (176° F.), in a porcelain vessel, until it becomes thick, pouring it out on a glass or porcelain plate, and drying it with a gentle heat. As thus obtained, ferric tannate is in flat pieces, of a crimson color, without taste, and insoluble in water. It is not a definite chemical compound. It acts as an astringent and tonic, and may be given in *chlorosis*. *Ink* is an aqueous solution of the ferric gallotannate, and probably possesses similar medicinal properties. It is a popular application for *ringworm*. *Dose* of ferric tannate, from eight to thirty grains (0.5–2.0 Gm.), in the course of the day.

Ferric Valerate. *Ferri Valerianas. U. S.* 1890. *Ferric Valerianate.* $Fe(C_5H_9O_2)_3$.—"Ferric Valerianate should be kept in small, well-stoppered bottles, in a cool and dark place." *U. S.* 1890.

This preparation, which was official in the old Dublin Pharmacopœia, was introduced into the United States Pharmacopœia, but was dismissed from the 8th Revision. It is rarely used, because of its insolubility. It may be made by precipitating a diluted solution of ferric sulphate with a solution of sodium valerate, and collecting and washing the precipitate.

It was officially described as "a dark brick-red, amorphous powder of somewhat varying chemical composition, having the odor of valerianic acid, and a mildly styptic taste; permanent in dry air. Insoluble in cold water, but readily soluble in alcohol. Boiling water decomposes it, setting free the vale-

riatic acid, and leaving ferric hydrate. When slowly heated, the salt parts with its acid, without fusing, but, when rapidly heated, it fuses and gives off inflammable vapors having the odor of butyric acid, and, on complete ignition, leaves a residue of ferric oxide. The stronger acids decompose the salt with the liberation of valeric acid. If 0.56 (0.5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 Cc.) in 2 Cc. of hydrochloric acid and 15 Cc. of water, and after the addition of 1 Gm. of potassium iodide the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled and mixed with a few drops of starch test-solution, it should require not less than 15 nor more than 20 Cc. of decinormal sodium hyposulphite volumetric solution to discharge the blue or greenish color of the liquid (each Cc. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.* 1890.

Uses.—Ferric valerate is a chalybeate tonic, which has been especially used by some practitioners in *anæmia* associated with *nervous exhaustion* and *hysteroid* states. It has also been alleged to have almost specific properties in *diabetes insipidus*. *Dose*, from two to five grains (0.13 to 0.32 Gm.).

Ferripyrrine. *Ferropyrrine*.—This compound is prepared by adding 5 parts of crystallized ferric chloride, dissolved in 10 parts of 96 per cent. alcohol, to a solution of 5 parts of antipyrine in 10 parts of alcohol and 50 parts of ether. It is in the form of a fine, orange-red powder, containing about 64 parts of antipyrine and 36 parts of anhydrous ferric chloride. Soluble in 5 parts of water at 15° C., less soluble (9 parts) in boiling water, very soluble in alcohol but insoluble in ether. Alkalies or alkaline carbonates added to an aqueous solution precipitate ferric hydroxide. It combines the properties of both antipyrine and ferric chloride and is given in *anæmic conditions* accompanied by *headache*. It has been used in *chlorosis* as a chalybeate; is strongly astringent, and affirmed to be often useful in chronic *diarrhæas*. In strong solution (1 to 5) it is said to be a powerful non-irritant styptic. *Dose*, from three to six grains (0.2 to 0.4 Gm.).

Ferrosol.—A double saccharate of ferrous oxide and sodium chloride. It contains 0.77 per cent. of iron, and is employed in *anæmia* and *chlorosis*.

Ferrostyptin.—A. Eichengrün has introduced this antiseptic hemostatic. It is a double salt of hexamethylene-tetramine hydrochloride and ferric chloride and forms dark yellow crystals, soluble in water. Its solution is coagulated by heat. *Dose*, five to eight grains (0.3–0.5 Gm.).

Ferrous Bromide. *Ferri Bromidum. Ferrum Bromatum. Bromure ferreux, Bromure de fer, Fr. Eisenbromid, Ferrobromid, G. FeBr₂*.—This bromide is obtained by heating gently, in thirty parts of water, two parts of bromine and one of iron filings. When the liquid has become greenish, it is filtered and evaporated to dryness in an iron vessel, and the dry mass, again dissolved and evaporated to dryness, furnishes the bromide. Ferrous bromide is a yellowish, deliquescent salt, very soluble, and extremely styptic. For medicinal employment it should be in aqueous solution, protected by sugar. Dillwyn Parrish has proposed the following formula. Take of bromine two hundred grains; iron filings eighty-five grains; distilled water four and a half fluidounces; sugar three ounces. Make a solution in the manner directed

for preparing solution of ferrous iodide. (See *Ferrous Iodide*.) For other formulas, see *P. J.*, 3d ser., v. 67, 162. This solution has been used with alleged success as an alterative tonic in *chorea*, and in various *scrofulous* and *erysipelatous* affections. (See 16th ed. *U. S. D.*) The dose of ferrous bromide is from one to three grains (0.065–0.2 Gm.), three times a day, gradually increased until its effects are manifested.

Ferrous Iodide. *Ferri Iodidum. Iodide of Iron. Iodure de Fer, Fr. Ferrum Iodatum. Eisenjodür, Jodeisen, G.*

"Take of Fine Iron Wire one ounce and a half [avoirdupois]; Iodine three ounces [avoir.]; Distilled Water fifteen fluid ounces. Put the Iodine, Iron, and twelve [fluid] ounces of the Water into a flask, and, having heated the mixture gently for about ten minutes, raise the heat and boil until the froth becomes white. Pass the solution as quickly as possible through a wetted calico filter into a dish of polished iron, washing the filter with the remainder of the Water, and boil down until a drop of the solution taken out on the end of an iron wire solidifies on cooling. The liquid should now be poured out on a porcelain dish, and, as soon as it has solidified, should be broken into fragments, and enclosed in a well-stoppered bottle." *Br.* 1867.

The solid ferrous iodide in its unprotected state is omitted in the present editions of the *U. S.* and *Br. Pharmacopœias*. The former directs it in pills and syrup prepared immediately from the materials. The iodide is extremely liable to spontaneous change.

In the *Br.* process of 1867, which is a modification of that of the old *Dublin Pharmacopœia*, iron is made to unite with iodine by the intervention of water, and the combination takes place readily and quickly. The liquid at first is red or orange colored, from the circumstance that all the iodine has not united with the iron; but, after the application of heat, it becomes fully saturated and limpid, and assumes a greenish color. It is now a solution of ferrous iodide, and yields the solid salt by evaporation. The proportion of the iron taken is half the weight of the iodine. Fine iron wire, recently cleaned, is directed on account of its purity; but iron filings dissolve more readily, and, if carefully selected, will be sufficiently pure. It is exceedingly difficult to obtain the salt in the solid state perfectly pure, so great is the proneness of its solution to absorb oxygen, whereby the iodide becomes, in part, converted into sesquioxide. This change is prevented to a certain extent by evaporating in an iron vessel.

T. and H. Smith of Edinburgh, recommend the following improved process, which more effectually excludes atmospheric air. Boil, in a Florence flask, six drachms of pure iron filings with two ounces and a quarter of iodine, in four and a half ounces of distilled water, until the liquid loses its dark color. Then filter the liquid rapidly into another flask, and evaporate it, at a boiling heat, until its green shade passes into black.

¹ *Tasteless Iron Iodide* is prepared in the following manner: 120.3 grains of iodine are combined with iron in the usual way to obtain the solution of ferrous iodide; this is filtered and 69 grains of iodine are dissolved in it; a solution of 201 grains of citric acid is exactly saturated with potassium hydroxide and then added to the first solution. When the apple-green color has been developed, the solution is evaporated, with gentle stirring, to dryness, when cauliflower-like masses of acicular crystals will be obtained. These are stable except in direct sunlight.

After this period, the heat is kept up as long as the evaporation of moisture continues, which may be ascertained by its condensation on a cold piece of glass, placed, from time to time, over the mouth of the flask. When this ceases, the flask contains pure, anhydrous, spongy ferrous iodide, which, when cold, is to be removed by breaking the flask, bruised coarsely in a warm dry mortar, and enclosed immediately in small well-corked bottles. If it be wished to obtain the iodine as a crystallized hydrate, the heat is to be withdrawn as soon as the liquid is sufficiently concentrated to congeal, in a dry and hard crust, on the end of an iron wire dipped into it. For a modification of this process, see *A. J. P.*, 1859, 52.

Ferrous iodide is a crystalline substance, exceedingly deliquescent, of a greenish-black color, and styptic, chalybeate taste. Its solution, by evaporation with as little contact of air as possible, affords transparent, green, tabular crystals. When heated moderately it fuses, and, on cooling, becomes an opaque crystalline mass, having an iron-gray color and metallic lustre. At a higher temperature it emits violet colored vapors, and the iron is left in the state of sesquioxide. It is very soluble both in water and in alcohol. When recently prepared it is wholly soluble in water, forming a pale green solution; but, if made for some time, it almost unavoidably contains some ferric oxide, from a partial decomposition, and will not entirely dissolve. Lecoq of Saint-Quentin, has proposed to preserve it in a wide-mouthed, ground-stoppered bottle, covered with a layer of reduced iron, which cannot decompose it, and protects it from the action of the air. When the iodide is wanted, the iron is removed with a bone spatula or a little brush. The aqueous solution is very liable to spontaneous decomposition, becoming at last orange-red from the generation of free iodine, and depositing ferric oxide. According to Richard Phillips, Jr., the first step in this change is the formation of ferrous oxide and hydriodic acid, from the decomposition of water. As the ferrous oxide immediately begins to be converted into ferric oxide by absorbing oxygen from the air, and in this state is precipitated, the hydriodic acid is set free, and hence is explained the acidity of the solution from the first moment the ferric oxide is deposited. Afterwards, the hydriodic acid is decomposed by the air, and iodine liberated. When the solution is prevented from generating free iodine, by placing in it a coil of iron wire, according to the plan of Squire, the iron acts by combining with the iodine of nascent hydriodic acid, and not with nascent iodine. (*P. J.*, iv. 19.) The plan of Squire does not prevent the deposition of ferric oxide, and has, therefore, been superseded by the use of saccharine matter, which affords a better protection to the solution. (See *Syrupus Ferri Iodidi*.) Ferrous iodide is incompatible with alkalies and their carbonates, with lime water, and with all other substances by which ferrous sulphate is decomposed. When crystallized, it has the composition $\text{FeI}_2 \cdot 5\text{H}_2\text{O}$.

Ferrous iodide was first employed in medicine by Pierquin in 1824. It was first used in the United States in 1832 by Samuel Jackson. Its properties are those of a tonic, alterative, and diuretic. It acts more like the preparations of iron than like those of iodine. It sometimes sharpens the appetite and promotes digestion, and occasionally proves laxative. When it does not operate on the bowels, it generally augments

the urine. Its use blackens the stools and lessens their fætor. It is chiefly employed in *scrofulous complaints, swellings of the cervical glands, chlorosis, atonic amenorrhæa, and leucorrhæa*. In *secondary syphilis*, occurring in debilitated and scrofulous subjects, Ricord has found it a valuable remedy. The dose is a grain (0.065 Gm.), gradually increased to eight grains (0.5 Gm.).

This salt, on account of its deliquescent property and proneness to decomposition, should not be given in pill, unless protected from change by saccharine matter or other means. (See *Pilula Ferri Iodidi* and *Ferri Iodidum Saccharatum*, p. 1225.) The most convenient form of exhibition is that of syrup, or glycerite.¹ Iron iodates have been used to some extent as therapeutic agents in Dublin. For formulas, see *P. J.*, i. 624.

Ferrous Lactate. *Ferri Lactas*. U. S. 1890. $\text{Fe}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 3\text{H}_2\text{O} = 285.88$. Lactate of Iron. *Ferrum Lacticum*, P. G. *Lactas Ferrosus*. *Lactate de Fer*, Fr. *Milchsaures Eisenoxydul*, *Eisenlactat*, G.

A formula for this salt was omitted in the 1880 U. S. P. revision. In the process of the U. S. P. 1870 the lactic acid unites with the iron, forming ferrous lactate, a part of which crystallizes when the solution cools, and the remainder is obtained by evaporation and crystallization. It may be more cheaply prepared, on the large scale, by digesting the impure acid first obtained in Louradour's process, with iron filings, or by reaction between ferrous sulphate and the calcium lactate prepared as a step in obtaining lactic acid. The following is Goble's process for making calcium lactate preparatory to its conversion into ferrous lactate. Add to 2 pints of skim milk, diluted with twice its bulk of water and contained in an earthen dish, 64 drachms of powdered lactose and 51 drachms of powdered chalk. Allow the whole to ferment for eleven or twelve days, at a temperature of from 26.6° to 32.2° C. (80°–90° F.), supplying fresh water as it evaporates. Transfer the liquor to a capsule, heat it gradually to boiling and stir it constantly. Boil for a quarter of an hour to coagulate casein, allow the insoluble matters to subside, and strain the liquid through flannel. The clear liquid is a solution of calcium lactate. In this process the casein of the milk, acting as a ferment, converts not only the lactose of the milk, but the lactose added, into lactic acid, a result which would not take place were it not for the presence of the chalk, which saturates the lactic acid as it is formed, and prevents it from uniting with the casein, whereby the power of the latter as a ferment would be destroyed. (*J. P. C.*, 3e sér., vi. 54.) See also other methods under *Acidum Lacticum*.) Calcium lactate may be expeditiously converted into iron lactate by the following process of Lepage. Dissolve 100 parts of calcium lactate, obtained by Goble's process, in 500 parts of boiling water; dissolve also 68 parts of pure crystallized ferrous sulphate in 500 parts of cold distilled water. Mix the fil-

¹ *Glycerite of Ferrous Iodide*.—Glycerin has the property, at once of dissolving and preserving ferrous iodide, and therefore makes an excellent solvent. Vezé proposes the following formula: "Take of iodine 70 parts, iron, in powder, 85 parts, and glycerin 400 parts. Mix them." The color of the solution is an emerald-green; its taste is bitter and astringent; and tests do not detect in it the presence of free iodine. It may be used for preparing the syrup or pills. Five grains of it contain one of ferrous iodide.

tered solutions in a flask, acidulate slightly with lactic acid, and heat in a water bath, stirring frequently until the double decomposition is completed. Then filter to separate the calcium sulphate, and evaporate rapidly to one-half, either in an iron vessel, or in a porcelain capsule containing a few turnings of iron. Filter again, and set aside to crystallize, and, having washed the crystals in a funnel with a little alcohol, dry them on bibulous paper. (*J. P. C.*, 3e sér., ix. 272.) In relation to the precautions to be observed in preparing this lactate so as to prevent the partial oxidation of the iron, see *A. J. P.*, 1853, p. 556.

Ferrous lactate is in "pale greenish-white crusts, consisting of small, needle-shaped crystals, having a slight, peculiar odor, and a mild, sweetish, ferruginous taste. Slowly but completely soluble in 40 parts of water at 15° C. (59° F.), and in 12 parts of boiling water; freely soluble in a solution of an alkali citrate, yielding a green solution; almost insoluble in alcohol. When strongly heated, the salt froths up, gives out dense, white, acrid fumes, chars, and finally leaves a brownish-red residue. The aqueous solution of the salt has a greenish-yellow color, a slightly acid reaction, and gives with potassium ferricyanide test-solution a deep blue, and with potassium ferrocyanide test-solution a light blue, precipitate. A 2-per-cent. aqueous solution of the salt should not afford with lead acetate test-solution, nor, after acidulation with hydrochloric acid, with hydrogen sulphide test-solution, more than a whitish opalescence (limit or absence of sulphate, chloride, citrate, tartrate, malate, etc., and of foreign metals). The aqueous solution, acidulated with nitric acid, should not afford more than a slight opalescence with barium chloride test-solution, or with silver nitrate test-solution (limit of sulphate or chloride). If 25 Cc. of the aqueous solution (1 in 50), mixed with 5 Cc. of diluted sulphuric acid, be boiled for a few minutes, then precipitated by an excess of potassium or sodium hydrate test-solution, the filtrate, mixed with a few drops of alkaline cupric tartrate volumetric solution, and heated to boiling, should not afford a red precipitate (absence of sugar). If a portion of the salt be triturated with strong sulphuric acid, no offensive odor should be developed (absence of butyric acid), nor should any gas be evolved (absence of carbonate), and the mixture, after standing for some time, should not assume a brown color (absence of sugar, gum, or other readily carbonizable impurities). If 1 Gm. of the salt, contained in a porcelain crucible, be moistened with nitric acid, and carefully ignited, it should leave a residue of ferric oxide weighing not less than 0.270 nor more than 0.278 Gm. This residue should not have an alkaline reaction upon litmus paper, nor yield anything soluble to water (absence of foreign salts)." *U. S.* 1890. Ferrous lactate has an acid reaction. The aqueous solution quickly becomes yellow, in consequence of the iron passing to a higher state of oxidation. Louradour has seen several samples of this lactate variously adulterated, as with effloresced ferrous sulphate, starch, and lactic acid, the sophistication being concealed by the sale of the salt in powder. These impurities may be detected by appropriate reagents, but Louradour recommends the rejection of the salt when it is not in crystalline form.

Medicinal Properties.—Ferrous lactate has the general medicinal properties of the ferruginous

preparations, and has been especially used in chlorosis by Andral, Fouquier, Bouillaud, and other Parisian doctors. As much as twelve or even twenty grains (0.78–1.3 Gm.) may be given in the course of a day. It may be administered in lozenge, pill, or syrup. The *lozenge* may be made of one grain (0.065 Gm.) of the lactate to twelve grains (0.78 Gm.) of sugar; the *pill*, of one grain (0.065 Gm.) of the salt, with an equal weight of some inert powder free from astringent matter, and sufficient honey. The following is the formula for a *syrup* proposed by Cap: Take of ferrous lactate a drachm; white sugar twelve ounces and a half; boiling distilled water six fluidounces and a half. Rub the salt to powder with half an ounce of the sugar, and dissolve the mixture quickly in the boiling water. Pour the solution into a flask placed on a sand bath, and add to it the rest of the sugar in small pieces. When the sugar is dissolved, filter the syrup, and, as soon as it is cold, transfer it to bottles, which must be well stoppered. This syrup has a very light amber color, and contains about four grains of the salt to the fluidounce. The dose is from two to four fluidrachms (7.5–15 Cc.). Bread, called *chalybeate bread*, containing ferrous lactate in the proportion of about a grain (0.065 Gm.) to the ounce (31 Gm.), has been used with advantage in cases of chlorotic patients in Paris.

Ferrous Malate. *Ferri Malas Crudus.*—This substance in an impure form has been long used and has been official in several European pharmacopœias under the name of *Extractum Ferri Pomatum*. It is made by digesting the juice of sour apples with iron filings until the reaction ceases, filtering and evaporating. Of a dark green color, containing varying amounts of iron.

Ferrous Oxalate. *Ferri Oxalas.* *U. S.* 1880. *Oxalate of Iron.* $\text{FeC}_2\text{O}_4 \cdot \text{H}_2\text{O}$. *Ferrum Oxalicum.* *Oxalas Ferrosus.* *Oxalate de Fer*, Fr. *Oxalsäures Eisenoxydul*, G.

"Take of Sulphate of Iron two troyounces; Oxalic Acid four hundred and thirty-six grains; Distilled Water a sufficient quantity. Dissolve the Sulphate of Iron in thirty fluidounces, and the Oxalic Acid in fifteen fluidounces of Distilled Water, filter the solutions, and, having mixed them with agitation, set aside the mixture until the precipitate is deposited. Decant the clear liquid, wash the precipitate until the washings cease to reddens litmus, and dry it with a gentle heat." *U. S.* 1870.

This salt was official in 1870 and 1880 and was properly dropped in 1890, as it is a very feeble, inefficient chalybeate. "A pale yellow or lemon-yellow, crystalline powder, permanent in the air, odorless and nearly tasteless, very slightly soluble in cold or hot water, but soluble in cold, concentrated hydrochloric acid, and in hot diluted sulphuric acid. When heated in contact with air, it decomposes with a faint combustion, and, on ignition, leaves a residue, amounting to not less than 49.3 per cent. of the original weight. On heating the salt with excess of test-solution of carbonate of sodium, it is decomposed, yielding a precipitate which, when dissolved in diluted hydrochloric acid, affords a blue precipitate with test-solution of ferricyanide of potassium, and a filtrate which, when supersaturated with acetic acid, yields, with test-solution of chloride of calcium, a white precipitate soluble in hydrochloric acid." *U. S.* 1880. *Dose*, from two to three grains (0.13–0.20 Gm.).

Fersan is stated to be a preparation of the iron compound contained in the erythrocytes of the fresh blood of cattle, which is chemically a *ferruginous paranucleo-proteid*. It is soluble in water; the solution does not coagulate when boiled, and is not completely absorbed until it reaches the intestine. According to experiments made upon the lower animals, it remarkably increases the hæmoglobin of the blood and it has been used by various clinicians in the treatment of *anæmias*. *Dose*, a small teaspoonful after meals.

Filmogen. *Liquor Adhesivus*.—A vehicle for the application of medicinal substances to the skin. It is said to be a solution of pyroxylin in acetone containing a trace of fixed oil. It forms an elastic coating impervious to water.

Flindersia. *Flindersia maculosa* (Lindl.), F. Muell. *Leopard Tree*.—This is a tree of New South Wales, belonging to the Meliaceæ. During the summer it yields large masses of a clear amber-colored gum, which has a pleasant taste and is eaten by the aborigines; it is used as a remedy for *diarrhæa*. *Leopard tree gum* occurs in pieces as large as pigeons' eggs; dissolves rapidly in cold water, and has been found by J. H. Maiden to contain eighty per cent. of arabin but no metarabin. (*P. J.*, vol. xxi. 1890.)

Flour.—Under name of *Farina Triticæ* the Br. Pharmacopœia formerly recognized ordinary wheat flour. *Bran* is the husk separated from the wheat during the process of grinding, and constitutes from 25 to 33 per cent. of the whole yield.

Flour is white, inodorous, and nearly insipid. Its chief constituents are starch, gluten, albumen, saccharine matter, and gum, the proportions of which are not constant. Clifford Richardson (*Bulletin No. 9, U. S. Department of Agriculture*, 1886) gives as the average of 27 analyses of wheat the following composition: moisture, 9.25; ash, 1.84; oil, 2.30; sugar, 3.50; dextrin and soluble starch, 2.30; starch, 67.88; albuminoids soluble in 80 per cent. alcohol, 3.58; albuminoids insoluble in 80 per cent. alcohol, 7.45; fibre, 1.90; total, 100. The gummy substance found in wheat flour is not precisely identical with ordinary gum, as it contains nitrogen, and does not yield mucic acid by the action of nitric acid. The starch, which is by far the most abundant ingredient, is much employed in a separate state. (See *Amylum*.) The gluten, however, is not less important, as it is to the large proportion of this principle in wheat flour that it owes its superiority over that from other grains for the preparation of bread. The gluten here referred to is the substance first noticed as a distinct principle by Beccaria. It is the soft, viscid, fibrous mass which remains when wheat flour enclosed in a linen bag is exposed to the action of a stream of water and at the same time pressed with the fingers till the liquor comes away colorless. But this has been ascertained to consist, in fact, of two different substances. When boiled in alcohol, one portion of it is dissolved, while another remains unaffected. Einhof ascertained that the part of the glutinous mass left behind by alcohol is identical with *vegetable albumen*, while the dissolved portion only is strictly entitled to the name of *gluten*, which had been previously applied to the whole mass. These two principles are contained in numerous vegetable products. They both contain nitrogen, and both, when left to themselves in a moist state, undergo putrefaction. From these circumstances, and from their close resemblance to certain proximate animal principles in chemical habitudes and

relations, they were sometimes called, in old works on chemistry, *vegeto-animal substances*. They are separated from each other by boiling the gluten of Beccaria, above referred to, with successive portions of alcohol, until the liquid, filtered while yet hot, ceases to become turbid on cooling. The proper gluten dissolves, and may be obtained by adding water to the solution and distilling off the alcohol. Large cohering flakes float in the liquor, which, when removed, form a viscid, elastic mass, consisting of the substance in question with slight impurity. The part left behind by the alcohol is coagulated albumen.

Pure *gluten*, sometimes called *vegetable fibrin*, is a pale yellow, adhesive, elastic substance, which by drying becomes more deeply yellow and translucent. It is almost insoluble in water, and quite insoluble in ether and in the oils, both fixed and volatile. Hot alcohol dissolves it much more readily than cold, and from its solution in boiling alcohol it separates unchanged when the liquor cools. It is soluble in dilute acids, and in caustic alkaline solutions, in consequence of forming soluble compounds with the acids and alkalis. With the earths and metallic oxides it forms nearly insoluble compounds, which are precipitated when earthy or metallic salts are added to the solution of gluten in solution of potassium hydroxide. Corrosive sublimate precipitates it from its acid as well as alkaline solutions, and, added in solution to moist gluten, forms a compound with it, which, when dry, is hard, opaque, and inconvertible. Gluten is precipitated by infusion of galls. Its name originated in its adhesive property. It exists in most farinaceous grains and in the seeds of some leguminous plants.

Vegetable albumen is destitute of adhesiveness, and, when dried, is opaque and of a white, gray, or brown color. Before coagulation, it is soluble in water, but insoluble in alcohol. By heat it coagulates and becomes insoluble in water. It is dissolved by solutions of the caustic alkalis. Most of the acids, if added to its solution in excess, precipitate the albumen, which, though soluble in pure water, is insoluble in that liquid when acidulated. It is not, however, precipitated by an excess of phosphoric or acetic acid. Corrosive sublimate precipitates it from its solutions, except from those in phosphoric and acetic acids, and, when added in a state of solution to moist albumen, forms with it a hard, opaque compound. It is also precipitated by infusion of galls. This principle derived its name from its very close resemblance to animal albumin. It is associated with gluten in most of the farinaceous grains, is a constituent of all the seeds which form a milky emulsion with water, and exists in all the vegetable juices which coagulate by heat.

Vegetable albumen and *vegetable fibrin* (or gluten) both belong to the great class of *proteid* bodies, which class includes albumens, globulins, compound proteids, modified proteids, albuminoids, enzymes, and toxalbumins. *Proteids* consist of nitrogen, carbon, hydrogen, oxygen, and sulphur, and their average composition may be expressed by the empirical formula $C_{72}H_{112}N_{18}O_{28}S$.

It is scarcely necessary to state that *bread* is formed by making flour into a paste with water, with the addition of yeast, setting it aside to ferment, and then exposing it to the heat of an oven. The fermentation excited by the yeast is accompanied by the extrication of carbon dioxide, which, being retained by the tenacity of the gluten, forms innumerable little cells throughout the mass,

and thus renders the bread light.¹ Alcohol is also generated during the fermentation, most of which is driven off from the bread in baking; but a small portion remains, averaging, according to Thos. Polas, 0.314 per cent. (*Chem. News*, May 30, 1873.)

Wheat flour in its unaltered state is seldom used in medicine. It is sometimes sprinkled on the skin in *erysipelatosus* inflammation, and in various itching or burning eruptions, particularly the *nettle-rash*; though rye flour is generally preferred for this purpose.

Bread is more employed; an infusion of toasted bread in water is a nutritive drink well adapted to febrile complaints. Boiled with milk, bread forms a good emollient poultice, which may be improved by the addition of a little perfectly fresh lard. Slices of it steeped in lead water, and the crumb mixed with the fluid and confined within gauze, afford a convenient mode of applying this preparation to local inflammations. The crumb (*mica panis*) is, moreover, frequently used to give bulk to minute doses of very active medicines administered in the form of pill. It should be recollected that it always contains common salt, which is incompatible with various substances.

Bran is sometimes used in decoction, as demulcent in catarrhal affections and complaints of the bowels. When taken in substance, it is laxative, and may be used with advantage to prevent *costiveness*. Bran bread, made from the unsifted flour, is an excellent laxative article of diet in some dyspeptic cases. The action of the bran is probably mechanical, consisting in the irritation produced upon the mucous membrane of the bowels by its coarse particles. Bran also forms an excellent demulcent bath.

Fluorescence.—It has been proposed to use this property of various drugs to detect adulterations. (See *P. J.*, 1875; *A. J. P.*, 1875; *P. M. T.*, 1875.)

Fluorescin. Fluorescein. $C_{20}H_{12}O_5$.—This may be prepared by heating phthalic anhydride (5 parts) with resorcinol (7 parts) to 200° C. (392° F.). It is a yellowish-red or dark red powder, soluble in alcohol with yellow-red color and green fluorescence. The sodium salt *uranin* (*sodio-fluorescein*), $C_{20}H_{10}O_5Na_2$, and the potassium salt

(*potassio-fluorescein*) are marketed. They differ in that the first is a brownish-yellow and the second a yellowish-red powder; both of them yield aqueous solutions which exhibit an intense yellow-green fluorescence. These drugs were recommended by Straub in 1888 for the purpose of staining the eye and its secretions, under various circumstances, to facilitate diagnosis. The test solutions should contain fluorescin, 2 parts; sodium bicarbonate, 3 parts; distilled water, 100 parts. It is necessary to cocaineize the eye before the application of the fluorescin.

Fluorides.—*Hydrofluoric acid* is a pungent, fuming, acid gas, very corrosive, attacking glass and porcelain and etching its surface. It is very soluble in water, the specific gravity of the solution rising to 1.25. The concentrated aqueous acid becomes weaker on boiling until, when boiling at 120° C. (248° F.), it attains a constant composition of from 36 to 38 per cent. of the anhydrous acid. Concentrated hydrofluoric acid is a powerful corrosive, having the peculiar property of hardening the skin or tissue with which it comes in contact and continuing its action underneath the hardened tissue, with an extraordinary amount and persistency of pain. For case, see *B. M. S. J.*, Jan. 1882; also *B. M. J.*, vol. i. 1880. According to L. A. Waddell (*Indian Med. Gaz.*, 1883), the dilute 8 per cent. acid applied to the skin causes stinging sensation and pallor, followed by redness and desquamation. From 15 to 20 per cent. acid destroys the epithelium and produces severe burning and aching pain. The vapor of the acid is exceedingly irritant to the lungs, causing, even when very dilute, spasm of the glottis and other symptoms of irritation. According to Husemann, death has been produced by it. Nevertheless, L. Olivieri and F. Mergoni affirmed that in solution of 33 per cent. the daily inhalation of hydrofluoric acid from half an hour to an hour is a valuable adjunct to quinine in chronic malaria.

Alkaline Fluorides.—Waddell states that the alkaline fluorides are not pronounced irritants, and when taken internally in *doses* of from a grain to a grain and a half (0.065–0.096 Gm.) continuously, they reduce the force and the frequency of the pulse, at the same time depressing the temperature and increasing somewhat the flow of urine, but not distinctly affecting either the respiratory or the cutaneous functions. This accords with the physiological studies of Tappeiner, who found in animals the soda salt to powerfully depress blood pressure by acting on the vasomotor centres. Death, after profound collapse, was produced by centric failure of respiration. (*A. E. P. P.*, xxvii.) Waddell also affirms that there is an enormous decrease in the number of the red blood corpuscles, which he believes, but does not prove, to be the result of a direct action upon the spleen. According to the experiments of Brandl and Tappeiner, when solid fluorides are given in minute quantities with the food, they become separated in the body, especially in the bones, where they form a crystalline combination. (*Z. B.*, x. 1892.) Maumené has asserted that when the alkaline fluorides are given to dogs for five months goitrous enlargement of the thyroid gland is developed. On the other hand, Rabuteau failed in a series of experiments to obtain any such results, and Woakes has employed the remedy in goitrous enlargement of the thyroid with asserted good results. The remedy has also been used by Da Costa in rheumatism, but in the clinical studies of Waddell the fluorides failed to do any good

¹ *Adulteration of bread.*—Among the adulterations of bread practised by the bakers, alum, employed to cause whiteness and thus cover defects in the flour, is perhaps the one which has most attracted notice, and which, being sometimes noxious, it is most important to be able to test. One of the means of detection recommended is that of incineration, by which the bread is consumed, while the alum, if there be any, is left behind. But this method is somewhat tedious, and logwood has been recommended as being at once most convenient and, according to John Horsley, "*perfectly reliable*," if applied as he directs. The following is Horsley's method, by which in the county of Gloucester, England, alone, in the course of two surveys, he succeeded in obtaining two hundred convictions out of some thousands of cases examined by him. He first makes a tincture of logwood by digesting, for eight hours, two drachms of freshly cut chips in five ounces of methylated spirit and filtering; next makes a saturated solution of ammonium carbonate in distilled water; then mixes a teaspoonful of each solution with a wineglass of water in a white-ware dish, thus forming a pink-colored liquid, and lastly immerses a portion of the suspected bread, "for five minutes or so," in the mixed fluids. If alum be present, the bread, placed on a plate to drain, will in the course of an hour or two assume a blue color; if not present, the pink color will fade away. The appearance of a greenish color on drying will indicate the presence of copper. (*Chem. News*, May 17, 1872.) For some modifications of this method by Herz, see *A. Pharm.*, 1886, 676.

either in *rheumatism* or in *epilepsy*, although they did seem to accomplish something in *goitre*. Dose of the alkaline fluorides, one grain (0.065 Gm.). These fluorides are stated to be active antiseptics, and as such to be used in distilleries. Under the name of *fluorol*, Duclos has proposed the use of the *sodium fluoride* as being equally powerful and less toxic than the ordinary antiseptics. He reports that a 2 per cent. solution may be used upon the skin, mucous membranes, and wounds without irritation, and has used a half per cent. solution in diseases of the eye. According to Bokorny, it is much less powerful as a germicide than is the *potassium fluoride*. It is sometimes used as an insecticide, but is distinctly toxic, 150 grains having caused death. (*J. Am. C. S.*, xxi.)

Silver Fluoride, AgF. *Tachiol*.—This salt, which occurs in deliquescent crystals acquiring a yellow color in the air and finally being converted into a black crystalline mass, making stable solutions in water, has been brought forward by Durante and Perez as a valuable antiseptic for surgical use. It is a feeble coagulant of albumin, and great penetrating power is claimed for its solution. It is employed in the proportion of one to a thousand; the one per cent. solution is said not to be distinctly irritant to the skin. It blackens linen and other organic substances. Zappuli has destroyed *malignant pustules* by injecting into them silver fluoride solution.

Organic Fluorides.—A number of organic fluorine compounds have been proposed and put upon the market. According to Tischer and Beddies (*Aerzt. Rund.*, 1898), they are antispasmodic, bactericidal, and are primarily stimulant, secondarily depressant to the motor nerve. *Antitussin* is a five per

cent. ointment of *di-fluordiphenyl*, $\begin{matrix} \text{C}_6\text{H}_4\text{—F} \\ | \\ \text{C}_6\text{H}_4\text{—F} \end{matrix}$, which

has been lauded as a local application to the throat and chest in the treatment of *whooping cough*, one to one and a half drachms (3.9–5.8 Gm.) being applied at a time. *Di-fluordiphenyl* itself, a white aromatic powder, insoluble in water, freely soluble in alcohol, ether, and chloroform, was originally recommended by J. Thimm as a local remedy in the treatment of *syphilitic ulcers* or *wounds*, applied either as a ten per cent. dusting powder or a ten per cent. ointment. (*Derm. Zeit.*, iv. No. 15.)

Fluorphenetol has been introduced, in the form of a five per cent. ointment, under the name of *fluor-rheumin*, as a local application in *sciatica* and other acute affections.

Fluor-pseudocumol.—Under the name of *neodermin*, the five per cent. ointment of this substance has been put upon the market. It is alleged to have local properties similar to those of difluordiphenyl and especially to give relief to painful ulcers.

Fluoroform. CHF₃.—This gas was originally suggested by Stepp (*M. M. W.*, 1899, No. 29) in *tuberculosis*. Afterwards studied by Binz (*Verhandl. des Kongresses inn. Med.*, Berlin, 1891, vol. ii. Sec. iv.), who found it to have properties somewhat similar to those of chloroform. Under the name of *fluoroformol*, a two and eight-tenths per cent. aqueous solution has been introduced. It is almost odorless and tasteless, and is said to be non-toxic and non-irritant, so that four ounces a day may be given without the production of symptoms. Usually one fluidrachm (3.75 Gm.) has been administered in water four or five times a day. According to Stepp, it produces, when given inter-

nally, remarkable effects in *tuberculosis*. Gori (*M. M. W.*, 1899, No. 50) found it, however, to be of very little value.

Forman.—*Chlormethylmenthyl-ether*, C₁₀H₁₉—O.CH₂Cl, a product formed by the action of formaldehyde upon menthol in the presence of hydrochloric acid. It is a colorless oil, emitting dense fumes and boiling at 160° to 162° C. (320°–323.6° F.) under a pressure of 16 Mm. In the presence of water or merely moist air the ether splits up into its original constituents, formaldehyde, menthol, and hydrochloric acid, according to the equation:

therefore it is possible that when it is locally applied forman may act as nascent menthol and formaldehyde. It has been used in the treatment of various conditions of the nasal and even bronchial mucous membrane. It is applied either by inserting tufts of cotton impregnated with the compound loosely into the nostrils so that air may be aspirated through the nose, or by having the patient breathe the vapor arising from four to six drops of forman in warm water through a closed inhaler with nasal tips.

Formanilide. *Formanilidum*. *Phenylformamide*. C₆H₅NH.CO.H. This substance, which is made by heating aniline with formic acid, or by distilling equal molecules of aniline and oxalic acid, occurs in long, colorless, prismatic needles, melting at 46° C. (114.8° F.), soluble in water, alcohol, glycerin, and oil. It has been used as an antipyretic and analgesic, but is said frequently to produce cyanosis and cardiac depression. Externally, mixed with equal parts of chalk, it has been used in diseases especially of the nasal passages by Preisach, and in 2 per cent. solution by Meisel in *genito-urinary inflammations*. It is said to produce burning pain, lasting about a quarter of an hour, and followed by a mild analgesia continuing from eight to twelve hours. Dose, two to five grains (0.13–0.32 Gm.).

Formic Acid. *Acidum Formicum*, P. G. *Ameisensäure*, G.—This acid, although deriving its name from having first been obtained from the ant (*Formica rufa*), is remarkable for the number of sources of its production. It can be made from some species of caterpillars, from the blood, urine, fluid of the spleen, and perspiration of human beings; it is found in the products of decomposition of a number of vegetable substances, in common oil of turpentine, as a decomposition product of tartaric acid contained in various fruits and in the juice of the stinging nettle. It may be produced artificially in many ways: by the oxidation of methyl alcohol, the saponification of chloroform, and the hydrolysis of hydrocyanic acid; the following process yields good results: 50 Gm. of glycerin and 50 Gm. of crystallized oxalic acid are placed in a suitable retort attached to a condenser and the mixture carefully heated until the temperature rises to 105° C. (221° F.), it is then allowed to cool to about 50° C. (122° F.) and 50 Gm. more of oxalic acid are added and the mixture heated very slowly to 115° C. (239° F.). The condensed liquid may be drawn off and another addition of oxalic acid made and the distillation continued almost indefinitely. When oxalic acid and glycerin are distilled together, chemical reaction occurs, glyceryl formate being produced; this is saponified by the water which is separated, formic acid distills over and glycerin is reproduced. Formic acid, in its most concentrated state, is a colorless liquid,

sp. gr. 1.235 (medicinal acid, sp. gr. 1.063), fuming slightly upon exposure to the air, having a pungent sour taste, and, when applied to the soft skin, producing violent pain, and often ulceration. Diluted solutions are alone suitable for medicinal applications; equal parts of the strong acid and water have been used. *Spiritus Formicarum*, P. G., *Spirit of Ants, Ameisengeist*, G., is made as follows: "Alcohol (90-91 per cent. vol.), seventy parts; Water, twenty-six parts; Formic Acid (24-25 per cent.), four parts. Mix them. A clear, colorless liquid of an acid reaction. Specific gravity from 0.894 to 0.898." P. G.

When formic acid is mixed with solution of lead subacetate, it throws down a white, crystalline precipitate. "When the Acid is mixed with five parts of water and saturated by yellow mercuric oxide, a clear solution results, which, on heating, evolves a gas and deposits a white precipitate, which rapidly turns gray and afterwards changes into shining, metallic, coalescing globules. When neutralized with solution of potassium hydroxide, it should have no pungent or empyreumatic odor. 10 Gm. of the Acid should neutralize 56 to 58 Cc. of volumetric solution of soda, corresponding to 24 to 25 per cent. of soluble Formic Acid. When diluted with five parts of water, the Acid should not be affected by silver nitrate, nor, after neutralization with ammonia, by chloride of calcium nor by hydrosulphuric acid. On diluting 1.5 Gm. of the Acid with 5 Gm. of water and heating on the water bath as long as gas is given off with 1 Gm. of yellow oxide of mercury, it should yield a neutral filtrate." P. G.

Formic acid, diluted with an equal measure of water, is sometimes used to excite the circulation in paralyzed limbs. It is rarely used internally; dose, five minims (0.3 Cc.).

Among the salts of formic acid, ammonium formate (NH_4CHO_2) has been used medicinally. Ramskill, at the Hospital for the Epileptic and Paralytic, in London, considers it useful in chronic paralytic disease associated with general tremor. It is contraindicated by any remaining active irritation or inflammation of the nervous centres or about them, which may have been the original seat of the lesion. Gréhaut and Quinquaud have found that the formates are eliminated by the kidneys unchanged. Dose, five grains (0.32 Gm.); a larger quantity than this is apt to cause vomiting.

Formic Ether.—A paper on the physiological action of this substance may be found in the *J. P. C.*, Juin, 1872, 453.

Formopyrine.—*Methylenediantipyrine* ($\text{C}_{11}\text{H}_{11}\text{N}_2\text{O}_2 = \text{CH}_2$) is formed by heating five parts of antipyrine with four parts of formaldehyde solution for several hours to 120°C . (248°F .); crystals melting at 156°C . (312.8°F .), or when anhydrous at 176° to 177°C . (348.8° – 350.6°F .); almost insoluble in water, readily soluble in alcohol. It unites the action of the two components.

Fortoin is obtained by the action of formaldehyde upon *cotoin*, the active principle of the true coto-bark. Its composition is $\text{CH}_2 \begin{smallmatrix} \text{C}_{14}\text{H}_{11}\text{O}_4 \\ \text{C}_{14}\text{H}_{11}\text{O}_4 \end{smallmatrix}$ and it is therefore to be viewed in the light of a *methylenediacotin*. Fortoin forms yellow needles or a yellow powder emitting a feeble cinnamon-like odor; it is freely soluble in chloroform, acetone, glacial acetic acid, and dilute alkalies, but dissolves sparingly in alcohol and ether, while in water it is absolutely insoluble; melting point, 211° to 213°C . (411.8° – 415.4°F .). It is claimed

for *fortoin* that it has the peculiar action of *cotoin* upon the intestinal mucous membrane, united with the antiseptic and disinfecting properties of formaldehyde. It is used in those cases of *chronic intestinal catarrh* in which there is no active inflammatory process. It has been also recommended by Overlach as a local application in badly ulcerated sore throats and in gonorrhœa. In making local applications 10 per cent. of alcohol should be employed with water, and the strength may vary from one to six grains to the fluidounce. Dose, four to seven grains (0.26–0.45 Gm.) three to five times a day.

Frankenia. *Frankenia grandifolia*, Cham. and Schlecht. *Yerba Reuma*. (Fam. Frankeniaceæ.) This California herb, which contains about 6 per cent. of tannin, is employed as a topical remedy in *catarrhal affections*, especially of the nose and genito-urinary tract; also internally in doses of from ten to twenty minims (0.6 to 1.3 Cc.) of the fluidextract. For local application the fluidextract may be diluted with from two to five times its volume of water.

Frasera. *Radix Frasera*. *Radix Colombo Americana*. *Racine de Colombo de Mariette (d'Amérique)*, Fr. *Fraseraurzel*, *Amerikanische Colombowurzel*, G.

American Columbo (*Frasera carolinensis*, Walt.; *F. Walteri*, Michx.) flourishes in the southern and middle western region of the United States. It prefers rich woodlands and moist meadows. The period of flowering is from May to July; but the stems and flowers are produced only in the third year, the radical leaves being the only part of the plant which previously appears above ground. From this manner of growth, it is inferred that the roots, which were formerly included in the Secondary List U. S. P., should be collected in the autumn of the second or the spring of the third year. Before being dried, they should be cut into transverse slices.

As formerly in the market, *frasera* was in pieces irregularly circular, an eighth of an inch or more in thickness, about an inch in diameter, somewhat shrunk in the middle, consisting of a central medullary matter and an exterior cortical portion, of a yellowish color on the cut surfaces, with a light reddish-brown epidermis. In appearance these pieces somewhat resembled *calumba*, but were easily distinguishable by the greater uniformity of their internal structure, the absence of concentric and radiating lines, and their purer yellow color, without a greenish tinge. The root sliced longitudinally, so as to imitate gentian, has been offered in the market as *American gentian*. The taste of *frasera* is bitterish and sweetish. Water and diluted alcohol extract its virtues, and the tincture lets fall a precipitate upon the addition of water, but is not disturbed by tincture of galls. The hot infusion is not precipitated by solution of gelatin, and gives with iodine no signs of starch. These reactions afford additional means of distinguishing the root from *calumba*. Higginbotham of Bermuda, found in it gum, pectin, glucose, wax, resin, fatty matter, yellow coloring matter, bitter extractive, and an acid which was probably peculiar. (*A. J. P.*, Jan. 1862, 23.) Frank W. Thomas has determined the entire absence of berberine. (*Ibid.*, July, 1868, 310.) G. W. Kennedy obtained *gentisic acid*, $\text{C}_{14}\text{H}_{10}\text{O}_5$, and *gentiopierin*, $\text{C}_{20}\text{H}_{30}\text{O}_{12}$. (*Proc. A. Ph. A.*, 1873, 635.) Patch points out (*Ibid.*, 1881, 467) that the yellow coloring matter differs from *gentisic acid* in being less soluble in cold alcohol, more soluble in hot alco-

hol and in ether, in having a lower melting point, 86.1° C. (187° F.), and in behaving differently with nitric and sulphuric acids.

Fraxera, or *American Columbo*, is a feeble, simple bitter, *Dose*, of powder, one drachm (3.9 Gm.); of infusion (1 fl. oz. to 1 pint boiling water), two fluidounces (60 Cc.) a day. The fresh root is said to be emetic and cathartic.

Fraxinus. *Fraxinus americana*, L. *White Ash*. (Fam. Oleaceæ.)—The bark has been used in *dysmenorrhœa* by Charles P. Turner and others. The wine may be made (Thomas S. Wiegand, A. J. P., 1882) by macerating eight troyounces of powdered bark for three days in one pint of sherry wine, then transferring to a percolator, and pouring on sufficient menstruum to obtain two pints of percolate. *Dose*, one fluidrachm (3.75 Cc.).

Fraxinus excelsior, L. *Frêne*, Fr. *Esche*, G. *Fresco*, Sp. (Fam. Oleaceæ.)—The bark of the *Common European Ash* is bitter and astringent, and at one time was employed in the treatment of intermittent fever. Keller believed that he had found in the bark a peculiar crystallizable principle which Buchner denominated *fraxinin*; but Rochleder and Schwartz proved that the crystals, formed along with the bitter substance obtained by the process of Keller, were nothing but mannite. (Ph. Ob., 1853, 312.) *Fraxin* or *pavlin*, the crystallizable bitter principle discovered by Salm-Horstmar, is obtained by precipitating the decoction with lead acetate, washing the precipitate, decomposing it by hydrogen sulphide, and concentrating the solution, which deposits the fraxin in needle-shaped crystals. These are four-sided prisms, shining, white with a tinge of yellow, feebly bitter and astringent, inodorous, soluble with difficulty in cold but readily in hot water. They have the formula $C_{14}H_{18}O_{10}$. Fraxin is a glucoside, dilute acids decomposing it into *fraxetin*, $C_{10}H_8O_6$, and *glucose*, $C_6H_{12}O_6$. The concentrated warm solution has an acid reaction. When much diluted, it exhibits a clear blue fluorescence by daylight, especially if a trace of ammonia be present. Alkalies, alkaline earths, and the carbonates color it yellow; ferric chloride first colors it green, and then throws down a yellow precipitate. (Chem. Ob., 1857, 452.) The leaves have long been used in *rheumatic affections* and *gout*. Garot has shown that they contain 16 per cent. of *calcium malate*. (See J. P. C., 3e sér., xxiv. 311; also 4e sér., xii. 60.) *Dose*, an ounce (31 Gm.), infused in half a pint (236 Cc.) of boiling water, three times a day. (See Am. J. M. S., N. S., xxv. 492.)

French Chalk.—A compact, unctuous, indurated talc, of a greenish color, glossy, somewhat translucent, soft and easily scratched, and leaving a silvery line on paper; used chiefly for marking cloth and for extracting grease spots. (See *Talcum*.)

Fruit Essences, Artificial.—Several of the compound esters have been found to possess the odor and flavor of certain fruits, a property which has led to their employment as flavoring materials for confectionery and desserts, under the name of fruit essences. The simple ethers present in these compounds, so far as they have become of commercial importance, are common ether or ethyl oxide, and amyl oxide or amyl ether. Each of these ethers possesses basic properties, and has its alcohol, common or ethylic ether corresponding to common or ethyl alcohol, and amyl ether to amyl alcohol or fusel oil. These alcohols are hydroxides of ethyl and amyl respectively. (See

Amyl Alcohol, and *Alcohol*, page 103.) Colored artificial essences are to be distinguished from the real by the following tests, founded upon the presence of aniline dyes. Fuchsin dyes a woollen or silken thread a permanent rose color, the tint imparted by natural fruit juice washes out (C. Puscher, J. P. C., 4e sér., xlv. 395); dilute mineral acids redden natural fruit essences, turning yellow those containing an aniline dye; half a volume of nitric acid instantly turns an artificial syrup yellow; potassium carbonate reddens artificial syrups, but has no effect on natural syrups; lead subacetate precipitates red with fuchsin, green with natural fruit. (M. Vandeyvere, J. P. C., 4e sér., x. 457; Hagar, A. J. P., xlv. 395.)

Ethyl Butyrate. *Butyric Ether.* *Ethyl-butyric Ester.* $C_4H_7(C_2H_5)_2O_2$.—This ester is readily prepared by dissolving eight parts of normal butyric acid in five parts of ethyl alcohol and mixing this solution with ten parts of concentrated sulphuric acid. After warming the mixture for some time to about 80° C. (176° F.), and then allowing it to stand for some hours, it is poured into cold water, when the ether separates. It forms a layer on the surface, and may be purified by washing it with water and subjecting it to the action of calcium chloride. Butyric ether is sparingly soluble in water, but very soluble in alcohol, and boils at 121° C. (249.8° F.). It is said to be much used to communicate a pineapple flavor to rum. Dissolved in 8 to 10 parts of alcohol, it forms the *pineapple essence*. From twenty to twenty-five drops of this essence, added to a pound of sugar containing a little citric acid, imparts to the mixture a strong taste resembling that of pineapple. *Butyric acid*, $C_4H_8O_2$, is formed during what is called the butyric fermentation, which usually consumes two or three months before it is completed, and which is preceded by the lactic fermentation. To prepare it, a solution of grape sugar is mixed with half its weight of chalk, and with about one-tenth of its weight of cheese to act as a ferment, and the whole is kept at the temperature of 32.2° C. (90° F.). The sugar is first transformed into a viscous substance, and afterwards into lactic acid, which is gradually converted into butyric acid, with the disengagement of hydrogen and carbon dioxide. At the end of the fermentation the liquid contains principally a mixture of calcium butyrate and lactate, from which the butyric acid may be obtained by precipitating the lime as a carbonate by sodium carbonate, and decomposing the resulting sodium butyrate with sulphuric acid. Butyric acid is a colorless liquid, of disagreeable odor and rancid taste. It dissolves in all proportions in water and alcohol, boils at 163° C. (325.4° F.); density, 0.973.

Ethyl Pelargonate. *Pelargonic Ether.* *Ethyl-pelargonic Ester.* *Enanthic Ether.* $C_2H_5C_9H_{17}O_2$.—A preliminary step in forming this ether is to prepare the *pelargonic acid*. This is obtained, according to R. Wagner, by the action of nitric acid on oil of rue. Treat the oil with double its weight of very dilute nitric acid, and heat the mixture until it begins to boil. Two layers are formed in the liquid, the upper one being brownish, and the lower consisting of the products of the oxidation of the oil, with the excess of nitric acid. The lower layer, having been separated, is freed from the greater part of the nitric acid by evaporation in a zinc chloride bath, and then filtered. This filtrate is a solution of pelargonic acid, and may be converted into pelargonic ether by a pro-

longed digestion, at a gentle heat, with alcohol. The ether as thus prepared has the agreeable odor of quince, and when dissolved in alcohol in due proportion, forms the *quince essence*. It is also obtained from wine lees, by adding sulphuric acid and water, and distilling in a current of steam. Pure pelargonic ether (cinnanthic ether) is a colorless liquid, having a peculiar, vinous, stupefying odor, and a taste at first slight but afterwards acid. Its sp. gr. is 0.8635 at 17.5° C. (63.5° F.) and its boiling point from 227° to 228° C. (440.6°–442.4° F.). It is insoluble in water, but dissolves readily in alcohol and ether. Pelargonic acid, first obtained from *Pelargonium capitatum* (L.), Ait., or *rose geranium*, belongs to the fatty acid series and has the formula $C_{15}H_{31}O_2$. Delffs's analysis of *cinnanthic acid* gives it the same composition, and he considers the two acids identical.

Amyl Acetate. *Amyl-acetic Ester.* *Pentyl Acetate.* $C_5H_{11}.C_2H_3O_2$.—A cooled mixture of 100 parts of pure amyl alcohol and 130 parts of concentrated sulphuric acid is poured over 100 parts of anhydrous sodium acetate placed in a retort connected with condensing apparatus; after 12 hours' standing the ether is distilled off by the aid of a sand bath. The distilled liquid is purified from free acid by washing with a weak alkaline solution, and from water by distillation from calcium chloride. It is a colorless, limpid liquid, lighter than water, boiling at 137° C. (278.6° F.), insoluble in water, but soluble in alcohol. It possesses the odor, in a remarkable degree, of the Jargonelle pear, and is manufactured on a large scale for flavoring syrups and confectionery. An alcoholic solution of this ether forms the *Jargonelle pear essence*. Fifteen parts of amyl acetate, with half a part of acetic ether, dissolved in 100 parts of alcohol, form what may be called the *bergamot pear essence*, which, when employed to flavor sugar acidulated with a little citric acid, imparts the odor of the bergamot pear, and a fruity taste. Amyl acetate mixed with ethyl butyrate forms another fruity compound, which recalls the odor of the banana, and forms, in alcoholic solution, the *banana essence*.

Amyl Valerate. $C_5H_{11}.C_5H_9O_2$. **Amyl Valerianate.** *Amyl-valeric Ester.* *Apple Oil.*—This is made by carefully mixing four parts of pure amyl

alcohol (fusel oil) with four of sulphuric acid, and adding the mixture, when cold, to five parts of valeric acid. The whole is warmed for a few minutes in a water bath, and then mixed with a little water, which causes the ether to separate. Lastly, it is purified by washing it with water and a weak solution of sodium carbonate. It boils at 188° C. (370.4° F.), and has a sp. gr. of 0.879 at 0° C. (32° F.). An alcoholic solution of this ether, in the proportion of one part to six or eight of alcohol, forms a flavoring liquid under the name of *apple essence*. (See *Valeric Acid*.)

Besides the essences here described, there are found in commerce the strawberry, raspberry, apricot, greengage, mulberry, and black currant essences, all of which may be viewed as various mixtures of the esters of the ethyl and amyl series, modified by the addition of pure nitrous ether, tincture of orris, vanilla, volatile oils, etc., to bring about a resemblance to the fruit the odor and taste of which it is the object to imitate. In making these essences it is important that the materials should be pure, especially the fusel oil and alcohol. The alcohol used as a solvent should be rectified and deodorized.

The fruit essences are extensively employed for flavoring ices, jellies, lozenges, and drops, and for making fruit syrups and effervescent beverages. They are, however, vastly inferior to the concentrated juices and extracts from the real fruits, and if used at all should be free from injurious coloring agents.

Kletzinsky prepared a table giving the ingredients, and their proportions, of a large number of fruit essences. This table¹ has been carefully revised, as several important errors occurred in it. They are alcoholic solutions of different ethers, to which are sometimes added certain acid and natural essences. Glycerin is present in nearly all, being useful in blending and harmonizing the different flavors. The alcohol and other ingredients must be chemically pure. See a paper by George R. Pancoast and Willard Graham (*Proc. Penn. Phar. Assoc.*, June, 1906).

Fuchsine.—This product, one of the older coal tar colors, is either *rosaniline hydrochloride* or *acetate*, a complex body, the formula being $C_{20}H_{19}N_3.HCl$ or $C_{20}H_{19}N_3.C_2H_4O_2$. Both compounds

form large crystals of a greenish lustre, which dissolve in water (the acetate more easily in cold water) with carmine-red color. They stain animal tissue directly violet-red, while vegetable fibre must first be mordanted. Reiss (*G. H. M. C.*, 1888) recommends fuchsine as a specific in *acute and chronic Bright's disease*. Fuchsine and *safranine*, $C_{21}H_{20}N_4$, are said to be largely employed in France for coloring wines red. In the experiments of Cazeneuve and Lépine (*G. H. M. C.*, Nov. 1885) fuchsine was found to be free from toxic properties, but safranine proved itself a violent poison, causing marked dyspnoea, acceleration of the heart's beat, violent diarrhoea and albuminuria, and death from respiratory paralysis. Dose of rosaniline, one-tenth to one-sixth grain (0.006–0.010 Gm.).

Fucus vesiculosus. L. *Sea-wrack. Bladder-wrack. Kelp-ware. Black-tang. Cutweed. Curocus Marino.* *Fucus (Varech) vésiculeux*, Fr. *Blasentang. Seetang. Meereiche*, G. (Fam. *Fucaceæ*.) This sea weed is perennial, with the frond or leaf flat, smooth and glossy, from one to four feet long, from half an inch to an inch and a half broad, furnished with a midrib throughout its length, dichotomous, entire upon the margin, and of a dark olive-green color. Small spherical vesicles, filled with a mixture of nitrogen and oxygen but no CO_2 , are immersed in the frond near the midrib. The air in these vesicles has not the exact composition of the atmosphere, consisting, according to the analysis of Ernest Baudrimont, in one instance of 28.4 per cent. of oxygen and 71.6 of nitrogen, in another of 26.5 of the former and 73.5 of the latter. (*J. P. C.*, 4e sér., ii. 446.) The fruit consists of roundish, compressed conceptacles, at the ends of the branches, filled with a clear tasteless mucus and containing oogonia and antheridia on distinct plants. The plant grows upon the shores of Europe and of this continent, attaching itself to the rocks by its expanded woody root. On the coasts of Scotland and France it is much used in the preparation of *kelp*. It is also employed as a manure, and is mixed with the fodder of cattle. It has a peculiar odor, and a nauseous saline taste. Several chemists have undertaken its analysis, but the results are not satisfactory. It contains much sodium in saline combination, and iodine, according to Gaultier de Claubry, in the state of potassium iodide. Convoys have found in it 0.21 per cent. of iodine. (*P. J.*, x. 434.) These ingredients remain in its ashes, and in the charcoal resulting from its exposure to heat in close vessels. On the coast of France about a dozen species of sea weed have been used in making kelp. According to Eugene Marchand, *Fucus vesiculosus* is one of those poorest in iodine, the different species of *Laminaria* containing far larger amounts of iodine than the *Fucaceæ*. (See *P. J.*, 1884, 1011.) *Laminaria digitata* (L.), Lamx., and *L. stenophylla* contain ten times as much iodine as the *Fuci*, and are practically now the only kelps used in making iodine. (See *P. J.*, 1884, 1026.)

The charcoal, which is sometimes called *Æthiops vegetabilis* or *vegetable ethiops*, has long had the reputation of a deobstruent, and been given in *goitre* and *scrofulous swellings*. The mucus contained in the vesicles was applied externally, with advantage, by Russell, as a solvent in scrofulous tumors. Duchesne Dupare has obtained from it very good results in the treatment of morbid obesity. (*J. P. C.*, 1862, 65.) A. T. Carson affirms, however, that the *Fucus vesiculo-*

sus is largely used in Ireland for fattening pigs, and it is doubtful whether its preparations are capable of reducing human obesity unless given in such doses as to interfere with digestion and injure the health. Dannecey prepares the extract from the plant, collected at the period of fructification and rapidly dried in the sun. The coarse powder he treats for three days, with four times its weight of alcohol of 86°, expresses at the end of this time, and subjects the residue twice successively to a similar treatment with alcohol of 54°. The tinctures are then mixed, the alcohol distilled off, and the remainder evaporated to the consistence of an extract. Of this extract, which is one-fifth of the plant, three pills, each containing 0.25 Gm. (3.75 grains), may be taken daily in the beginning, and increased gradually to twenty-four pills. (*J. P. C.*, 1862, 434.) From the tincture a syrup may be prepared.

Other species of *Fucus* are in all probability possessed of similar properties. Many of them contain a gelatinous matter and a sweet principle analogous to mannite, and some are used as food in times of scarcity. Large quantities of a sea weed, *agar-agar*, are gathered on the rocky coasts of the East India islands, and sent to China, where it is valued for making jellies and as a size for stiffening silks. The varieties are classified by Fristedt as follows.

1.—*Ceylon Agar-agar*, consisting chiefly of *Sphaerococcus lichenoides*, Ag., the alga used by the *Hirundo esculenta* in the formation of its edible nest.

2.—*Macassar Agar-agar*, coming from the straits between Borneo and Celebes, consisting of impure *Eucheuma spinosum*, Ag., incrustated with salt.

3.—*Japanese Agar-agar*, known as Japanese isinglass, derived from several algæ, especially *Sphaerococcus compressus*, Ag., *Gloiopeltis tenax*, J. Ag., *Gelidium corneum*, Lam., and *G. cartilagineum*, Gaill. It occurs in European commerce either in transparent pieces, two feet long and as thick as a straw, prepared in Singapore by putting the algæ named in hot water, or, more frequently, in yellowish-white masses, a foot long and upward of an inch in width. It is the latter kind of agar-agar that is suitable for the culture of bacteria, according to Koch's method. (*P. J.*, 1885, 188.)

Morin has investigated the *gelose* of Payen, contained in the agar-agar. When a solution of gelose is cooled, even that of 1 in 500 parts of water, a colorless, transparent, and stiff jelly is obtained, which, when heated with moderately strong nitric acid, yields *mucic* and *oxalic acids*. It dissolves on heating with acidulated water without yielding a jelly on cooling.

Gelose leaves 3.88 per cent. of ash, and when air-dried contains 22.85 per cent. of moisture. When dissolved there also separates out a flocculent mass amounting to 1.9 per cent. Alcohol precipitates gelose, but it cannot be obtained pure in this manner, as the precipitate contains some ash. (*C. R. A. S.*, No. 90, 924–926.)

Under the name of *gelosine* a mucilaginous substance, extracted from a Japanese alga, has entered commerce in the form of dry, whitish leaves. Gelosine is soluble in alcohol and water, and is said when wet to gradually contract and expel water and the medicinal substances which it may contain. It has been proposed as a pharmaceutical basis for various preparations for local use. (See *B. M. J.*, vol. ii. 1886.) Glycerin suppositories have been made with agar-agar as a vehicle, but

they can contain but 70 per cent. of glycerin. The official suppositories, made with sodium stearate, contain 90 per cent. of glycerin.

The *Ceylon moss* is a delicate fungus (*Fucus amylaceus*) growing on the coast of Ceylon. It abounds in starch and vegetable jelly, and is used like carrageen or Irish moss. (P. J., xiii. 355.) (*Fucus Helminthochorton*, L., *Gigartina Helminthochorton*, Grev.) *Spharococcus Helminthochorton* (L.), Ag., has some reputation in Europe as an anthelmintic and febrifuge. It is an ingredient in the mixture of marine plants sold in Europe under the name of *Corsican moss* or *helminthochorton*. This is used in decoction, from four to six drachms to the pint; dose, a wineglassful three times a day.

Attention has been called by Sloan of Ayr, Scotland, to the *Laminaria digitata* (L.), Lamx., *L. Cloustoni*, Edmonst., commonly called sea-girdles or tangles, of Scotland, as supplying an admirable material for bougies. The stem is from two to twelve feet long and an inch or more in breadth, is of great strength and tenacity, with the property of drying readily, and, in doing so, of shrinking much, and acquiring an elastic firmness, with a consistence, if the desiccation be arrested at the proper point, somewhat softer than horn. In this state the plant may be kept for years, and is capable of absorbing moisture at any time and swelling to the original size, so that it has been used for the making of dilating bougies and tents.

Fuligokali.—This preparation, proposed by Deschamps, is formed by boiling for an hour 20 parts of potassium hydroxide and 100 of shining soot, in powder, in a sufficient quantity of water. The solution, when cold, is diluted, filtered, and evaporated to dryness. Fuligokali is in the form of a black powder, or of scales, very soluble in water, and having an empyreumatic odor and mild alkaline taste. It is used in the same affections as *anthrakokali*. The dose is two or three grains (0.13–0.2 Gm.), repeated several times a day. An ointment, containing from sixteen to thirty-two grains (1.04–2.13 Gm.) to the ounce (31 Gm.) of lard, was found by Gibert of Paris, to be detergent, resolvent, and gently stimulant. (A. J. P., xiv. 284.)

Fumaria. *Fumaria officinalis*, L. *Fumitory*. Beggary. *Fumeterre*, Fr. *Erdrauch*, *Feldraute*, G. (Fam. Papaveraceæ).—A small annual European plant, naturalized in this country, growing in cultivated grounds, and flowering from May to August. It was formerly considerably employed as a medicine, and is still used in Europe. The leaves are the official part. They are inodorous, have a bitter, saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract, prepared by evaporating the expressed juice or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. *Fumaric acid*, $C_4H_4O_4$, was early identified as present, and its isomerism with *maleic acid*, the acid obtained from malic acid by heat, was established later. The alkaloid *fumarine*, which was observed by Peschier, has been believed by some chemists to be identical with corydaline, but according to Reichwald (P. J., xix. 990) its formula, $C_{21}H_{19}N_3O_4$, is different from that of corydaline, from which it further differs in striking immediately an intense violet with concentrated sulphuric acid and an intense golden color with strong nitric acid. It occurs in colorless, tasteless crystals, freely soluble in chloroform, less so in benzene, still less so in alcohol and ether, sparingly soluble in water. He obtained

it by treating the pulp of the leaves with concentrated acetic acid, with the aid of heat, filtering, evaporating the liquid, treating the extract with boiling alcohol, filtering the alcoholic solution, and, finally, decolorizing, and evaporating so that crystals might form. The acetate thus procured was decomposed by the alkalis, and yielded the fumarine. (See Adermann, A. J. P., 1890, 396.) Fumitory has been considered gently tonic, alterative, and, in large doses, laxative and diuretic. Hannon has found fumarine, in the dose of about one-third or one-fourth of a grain (0.021–0.016 Gm.) to be moderately excitant; in that of three grains (0.2 Gm.) to be at first irritant and afterwards sedative. (Ann. Thér., 1854, 78.) Both in ancient and modern times fumitory has been esteemed a valuable remedy in visceral obstructions, particularly those of the liver, in scorbutic affections, and in various troublesome eruptive diseases. Cullen gave two fluidounces (60 Cc.) of the expressed juice twice a day. Others have prescribed it in much larger quantities. The leaves, either fresh or dried, may be used in decoction or extract, in almost indefinite dose. The inspissated juice has also been employed.

Furfurol. *Furol*.—*Pyromucicaldehyde*, $C_4H_3(CHO)O$, a decomposition product of certain proteids, occurs in beer and brandy and is produced in the distillation of bran, pentoses, etc., with diluted sulphuric acid. It is a limpid, colorless liquid, soluble in 11 parts of water and freely in alcohol and ether.

According to Brunton and Tunncliffe (L. L., 4032), this toxic aldehyde is present in all raw spirits and is the cause of their toxic properties. The dose of one and a half grains (0.096 Gm.) of furfurol produces in man a persistent headache. Ammonia is said to be antidotal to furfurol, hence its value in "pick-me-ups."

Fustic.—A yellow dye-wood, obtained from *Chlorophora tinctoria* (L.), Gaud. (*Morus tinctoria*, L., *Macura tinctoria*, D. Don, *Broussonetia tinctoria*, H. B. K.), a tree of the fam. Moraceæ, growing in the West Indies and South America. It is not used in medicine or pharmacy. According to Bancroft, two different woods bear in England the name of fustic, one the product of the tree just mentioned, distinguished as *old fustic*, probably from the greater magnitude of the billets in which it is imported; the other derived from the *Rhus cotinus*, L., or *Venice sumach*, and called *young fustic*, or sometimes *Hungarian fustic*. The wood of *C. tinctoria* owes its coloring properties to two principles, which have been isolated by R. Wagner; one denominated *morin*, or *morindon*, $C_{15}H_{10}O_6$, and the other *moritannic acid*, $C_{13}H_8O_6$, from its resemblance to tannin. The former, when distilled with zinc dust, yields methyl-anthracene, whence the conclusion has been drawn that it is a *trioxymethylanthraquinone*, $C_{16}H_7O_2(OH)_3$. (See Chem. Gaz., ix. 1, 21, and 241.) From the fustic of *Rhus cotinus*, L. (Fam. Anacardiaceæ), or Hungarian fustic, Chevreul extracted a yellow coloring matter, in small crystalline needles when pure, which he called *fisetin*. J. Schmidt (Ber. d. Chem. Ges., 19, 1734–1749) has made a thorough study of *fisetin*, and prepared a number of derivatives of it. He states that it occurs in the wood as a tannic acid compound of the glucoside of *fisetin*, which he calls *fustin*. This latter body crystallizes from hot water in fine silvery needles, easily soluble in alcohol and dilute alkalies, sparingly in ether. It melts at from 218°–219° C. (424.4°–426.2° F.)

with decomposition. By warming with dilute H_2SO_4 it is split up into fisetin and a glucose (probably *isodulcitol*). The *fisetin* has the formula $C_{15}H_{10}O_6$, and as it contains four hydroxyl groups, it is probably a *tetrocymethylantraquinone*, $C_{15}H_6O_2(OH)_4$. It is obtained by recrystallization from dilute alcohol or acetic acid; it forms fine yellow needles or yellow prisms. It is very slightly soluble in hot water, easily soluble in alcohol and acetic ether, sparingly in ether and benzene.

Gabianol is a substance prepared from a natural shale. It is described as a dark brown, oily liquid, with a greenish reflection, and as being a valuable remedy in various diseases of the lungs and throat, administered in capsules, each containing 4 grains (0.26 Gm.).

Gaiacyl.—C. André describes gaiacyl as being the calcium derivative of *guaiacol-sulphonic acid*, $(C_7H_7O_2SO_3)_2Ca$. It occurs as a bluish-gray powder very soluble in water and alcohol, but not in oil. It has been employed as a local anæsthetic in 5 to 10 per cent. solutions, but is probably of little value. (*J. P. C.*, Series 6, vol. vii.)

Galangal. *Galanga. China Root. India Root.* *Galanga*, Fr. *Rhizoma Galangæ*, P. G. *Galgant*, G.—Two varieties are described by authors, the *Galanga major* and *Galanga minor*, or *large* and *small galangal*. They are probably the roots of different plants. The large galangal is derived from *Alpinia Galanga*, Willd. (*Maranta Galanga*, L., *Galanga officinalis*, Salisb.). According to H. F. Hance of Canton, the smaller galangal is the product of a distinct but closely allied plant, *Alpinia officinarum*, Hance. (*A. J. P.*, xliii. 408.) Both forms are brought from the East Indies. The larger variety is cylindrical, three or four inches long, as thick as the thumb or thicker, often forked, reddish-brown externally, slightly striated longitudinally, marked with whitish circular rings, orange-brown internally, rather hard and fibrous, difficultly pulverizable, of an agreeable aromatic odor, and a pungent, hot, spicy, permanent taste. The small galangal resembles the preceding in shape, but is smaller, not exceeding the little finger in thickness, of a darker color, and of a stronger taste and odor. According to Morin, galangal contains a volatile oil, an acid resin, extractive, gum, bassorin, and lignin. A. Vogel, Jr., found also starch and fixed oil. (*Ph. Cb.*, 1844, 158.) R. Brandes discovered a peculiar crystallizable substance called *kampferid*. (*Ann. Pharm.*, xxxii. 311; see also *A. Pharm.*, 1882, 161.) The active principles are the volatile oil and acid resin. Thresh has described (*A. J. P.*, 1884, 553) an active pungent principle, which he has named *galangol*. Galangal is a stimulant aromatic. It was known to the ancient Greeks and Arabians, and formerly entered into numerous compounds. (*A. J. P.*, xliii.) Dose, from fifteen to thirty grains (1.0–2.0 Gm.) in substance, and twice as much in infusion.

Galega. *Galega officinalis*, L. *Goat's Rue. Herba Rutæ Caprariæ. Galega, Rue de Chèvre*, Fr. *Geisraute, Pestilenzkraut*, G.—A perennial leguminous herb, growing in the south of Europe, and sometimes cultivated in gardens. It is without odor unless bruised, when it emits a disagreeable odor. Its taste is unpleasantly bitter and somewhat rough, and when chewed it stains the saliva yellowish-brown. In former times it was much employed in malignant fevers, the plague, the bites of serpents, worms, etc. In 1873 Gillet-Damitte, in a communication to the French

Academy, stated that this plant when fed to cows would increase the secretion of milk from 35 to 50 per cent.; since which time Cerisoli, Goubeaux, Masson d'Aury, Millbank, and Carron de la Carrière have affirmed that goat's rue is a powerful galactagogue. The best preparation appears to be an aqueous extract prepared from the fresh plant. This almost black extract has a pronounced odor, and may be given in doses of from eight to fifteen grains (0.5 to 1.0 Gm.), from three to five times a day.

The root of the indigenous *Cracca virginiana*, L. (*Galega virginiana*, L., *Tephrosia virginiana*, Pers.), is said to be diaphoretic and powerfully anthelmintic. It is given in decoction.

Galium. *Galium Aparine*, L. *Cleavers. Goosegrass. Grateron*, Rièble, Fr. *Klebkraut*, G.—This is an annual, succulent, rubiaceous plant, common to Europe and the United States, growing in cultivated grounds, and along fences and hedges. It is inodorous, and has a bitterish, herbaceous, somewhat acid taste. Analyzed by Schwartz, it was found, besides chlorophyll, starch, and other principles common to all plants, to contain three distinct acids,—viz., a variety of tannic acid, which he names *galitannic acid*, citric acid, and a peculiar acid, previously discovered by Schwartz and Rochleder, and named *ribichloric acid*, $C_{14}H_5O_9$. (*P. J.*, xii. 190.) The expressed juice is said to be aperient, diuretic, and antiscorbutic, and has been used in dropsy, congestion of the spleen, scrofula, scorbutic eruptions, and lepra. Orwin (*T. G.*, vol. i. 767) commends it highly in *psoriasis*. Three ounces (90 Cc.) may be given twice a day.

Galium verum, L. *Yellow Ladies' Bedstraw. Cheese Rennet. Caille-lait jaune*, Fr. *Megerkraut, Liebfrauenstroh*, G.—This European *Galium* (Fam. Rubiaceæ) is inodorous, but has an astringent, acidulous, bitterish taste. The bruised plant is sometimes used to color cheese yellow, being introduced into milk before coagulation. It is also used for dyeing yellow. The roots of this and of most other species dye red, and the plant, eaten by animals, colors the bones like madder. Schwartz found the same principles in it as in *G. Aparine*. It was formerly highly esteemed as a remedy in *epilepsy* and *hysteria*, and was applied externally in *cutaneous eruptions*, in the form either of the recently expressed juice or of a decoction from the fresh plant. Of the American species, *G. tinctorium*, L., is closely allied in properties to *G. verum*. It is said to be useful in *cutaneous diseases*, and the root is employed by the Indians for staining their feathers and other ornaments red. *G. triflorum*, Michx., contains coumarin, as pointed out by L. von Cotzhausen. (*A. J. P.*, 1876, 405.)

Gallacetophenone. *Alicarine Yellow. C.*— $C_6H_2 \begin{cases} (OH)_3 \\ CH_3CO \end{cases}$ This is a derivative of pyrogallol, containing an acetyl group replacing an H atom of the benzene nucleus. Forms a pale yellow powder, crystallizing from hot water, in which, as well as in alcohol and ether, it is readily soluble. It is also soluble in glycerin in all proportions. This substance has been proposed as a substitute for pyrogallol in the local treatment of *psoriasis*, it being claimed that it does not stain, and is not so poisonous as the acid.

Gallinol. *Gallanol. Gallanilide.* $C_6H_2 \begin{cases} CO.NH.C_6H_5 \\ (OH)_3 + 2H_2O \end{cases}$ —This anilide of gallic acid is formed by boiling tannin with aniline, and was brought forward by Cazeneuve and Rollet as a

local remedy to replace chrysarobin in the treatment of skin diseases. (C. R. A. S., 1893.) It occurs in colorless crystals melting at 205° C. (401° F.), of a bitter taste, soluble in hot water, ether, and alcohol, insoluble in benzene and chloroform. It has been especially commended by Gonon, Bayet, Max Joseph, and others, not only in *psoriasis*, but also in chronic *eczema*, to be used in a 10 per cent. solution or ointment, or sometimes in very advanced cases as high as 20 per cent.; it is affirmed never to produce irritation. The removal of the hair is not necessary, provided the skin be thoroughly cleansed with alkaline soap solutions.

Gallobromol. *Dibromgallic Acid.* $C_6Br_2(OH)_2COOH$.—A colorless or pale grayish-red powder composed of fine needles melting at 205° C. (401° F.); soluble with difficulty in cold water, easily soluble in hot water, alcohol, and ether, and having a strong acid reaction and a slightly bitter taste. It has been used by Lépine in *neurasthenia* and *epilepsy* to replace potassium bromide, but it would seem to be a somewhat dangerous remedy, as in Lépine's experiments a dog weighing 11 kilogrammes was killed in two hours by 11 Gm., death having been preceded by slowing of the heart's action, depression of respiration, rise of temperature, convulsions, and methæmoglobinuria. According to Stein, it is to dogs more poisonous than the sodium bromide, less than the potassium bromide. In the dog small doses produce a primary moderate rise of the blood pressure, followed by fall of pressure, with cardiac arrhythmia. *Dose* (Lépine), as a sleeping potion, forty-five grains (3 Gm.); in *epilepsy*, from thirty to forty-five grains (2-3 Gm.) a day. (See *Cb. G. T.*, xiii. 1895.)

Gallols.—E. Kromayer (*Monatshefte für Prakt. Dermatologie*, vii.) has tested as remedies for diseases of the skin a number of chemical combinations of pyrogallol, chrysarobin, and resorcinol, with various acids. Of these a few give promise of therapeutic usefulness.

Lenigallol, pyrogallol triacetate, is described as a white insoluble powder, slowly soluble on warming with aqueous solutions of alkalies, with decomposition.

Eugallol, pyrogallol monoacetate, is a very thick, syrupy, transparent, dark yellow mass, readily soluble in water.

These substances are stated not to be affected by contact with healthy skin, but to be slowly decomposed by the diseased skin with the liberation of pyrogallol. Strong ointments of lenigallol are to be employed in *psoriasis*, 1 to 2 parts of lenigallol to 200 parts of zinc paste in *eczemas*. Even the most acute *eczemas*, as well as those with impetiginous crusty exudations, are reached by the ointment.

Eugallol produces great local excitement, and is only to be employed in the most obstinate cases of *psoriasis*. Under such circumstances, however, the direct local application as a paint, daily or every other day, produces a marked inflammation, under which the most stubborn patches are said to disappear. Dusting the painted parts with zinc oxide before drying makes the action more vigorous. The value of eugallol has been strongly confirmed by Paul Gruneberg (*Derm. Zeit.*, vi. 1899), who uses in *lupus* a zinc paste with from 11 to 12 per cent. of eugallol continuously applied after free curetting, and in *psoriasis* he uses a 33½ per cent. acetone solution followed by zinc oxide dressing.

Saligallol, pyrogallol disalicylate, is a resinous solid, useful in the preparation of skin varnishes, soluble in six parts of acetone or fifteen parts of chloroform. The deposit is very adhesive, but has no curative effect. It is useful as a means of applying eugallol.

Eurobin is *chrysarobin triacetate*.—It is insoluble in water, but is readily soluble in chloroform, acetic acid, acetone, or ether. It acts like chrysarobin on the skin, but is more powerful. Kromayer commends it applied as a paint, according to the following formula. Saligallol, 5 to 10 parts; eurobin, 1 to 20 parts; acetone, to make 100 parts.

Lenirobin, chrysarobin tetra-acetate, is less irritant than chrysarobin, and has the special advantage of not staining the linen.

Euresol, resorcinol monoacetate, is a viscid, rather fragrant, transparent, yellow mass, which is commended by Kromayer in *acne rosacea*, *seborrhœa*, and other conditions for which resorcinol is commonly used.

Gardenia. *Gardenia grandiflora*, Lour. (Fam. Rubiaceæ).—A Chinese tree, the fruit of which is employed in dyeing the yellow robes of the mandarins, and, according to Lorenz Mayer, contains *crocin*, which in powder is of a bright red color, and soluble in water and alcohol. According to the researches of Kayser (*Ber. d. Chem. Ges.*, 1884, 2228), its formula is $C_{44}H_{70}O_{28}$. When heated with diluted hydrochloric or sulphuric acid, it is decomposed into *crocin*, $C_{34}H_{46}O_8$, and a dextrorotatory sugar called *crocose*. Alkalies bring about the same decomposition almost instantly. Concentrated sulphuric acid dissolves both the *crocin* and *crocin* with deep blue color. The fruit of another species, *G. campanulata*, Roxb., growing in the forests of Chittagong, in India, is said to be used by the natives as a cathartic and anthelmintic. (Lindley, *Flor. Med.*, 434.)

Garrya Fremontii, Torr. *California Fever Bush.* *Skunk Bush*.—The leaves of this California bush (Fam. Cornaceæ) have an intensely bitter taste, and are said to be largely used by Californians as a tonic and antiperiodic. D. W. Ross (*A. J. P.*, 1877) states that he has found in them a new alkaloid, *garryine*. The dose of the fluid-extract of the leaves is from ten to thirty minims (0.6-1.8 Cc.).

Gasu-Basu.—This is an amorphous, yellow, hygroscopic powder, easily soluble in water, less soluble in ether and alcohol, giving alkaloidal reactions, and is said to be the active principle of the Indian gasu-basu. It has been brought forward as a local anæsthetic in the form of hydrochloride under the name of *nervocidine*.

Gaultheria. *Wintergreen.* *Bowberry.* *Chequerberry.* *Feuilles de Gaultherie couchée* (de Paloninier), *Thé du Canada*, *Thé de Terreneuve*, Fr. *Canadisoher Thee*, *Bergthee*, G.—*Gaultheria procumbens*, L. (Fam. Ericaceæ), is a small indigenous, shrubby, evergreen plant. The leaves, which were formerly official in the U. S. Pharmacopœia, are short-petiolate, obovate or roundish-oval, about an inch and a half (4 centimeters) long, and three-quarters of an inch (2 centimeters) or more broad, acute, revolute at the edges with a few mucronate serratures, coriaceous, shining, bright green above, paler beneath, of unequal size, and supported irregularly on short red petioles.

The plant extends from Canada to Georgia, growing in large beds in mountainous tracts, or in dry barrens and sandy plains, beneath the shade of shrubs and trees, particularly of other

evergreens, as the *Kalmia* and *Rhododendron*. In different parts of the country it is variously called *partridge-berry*, *deer-berry*, *tea-berry*, *wintergreen*, and *mountain-tea*. The flowers appear from May to September, and the fruit ripens at corresponding periods. To the very peculiar aromatic odor and taste which belong to the whole plant the leaves add a marked astringency. The aromatic and medicinal properties of wintergreen reside exclusively in an official volatile oil. (See *Oleum Gaultheriæ*, page 846.)

Gelanth. *Gelanthum*.—Gelanth is a combination of equal weights of tragacanth and gelatin, prepared by Unna as a basis for various pastes for the skin. It is stated to be superior to the older pastes in drying more quickly and leaving a smoother coating upon the skin, as well as in holding more uniformly and in tighter suspense the drug used with it, and finally in not spoiling readily. It is made by allowing tragacanth to soften with twenty times its mass of water for four weeks, then warming the mass to fluidity with steam and pressing it through a mill. In the meanwhile gelatin has been softened in the water and then for some time exposed to a high pressure of steam in Unna's boiler, which exposure lessens its capability of gelatinization. The mixture of the two masses is allowed for two days to soften in the steam, then passed through a mill and mixed with 5 per cent. of glycerin, a little rose-water, and 2 per cent. of thymol. The finished gelanth contains about $2\frac{1}{2}$ per cent. each of dry gelatin and tragacanth. In using it as a vehicle, fatty matters must first be emulsified and insoluble substances rubbed up with water to a soft paste before they are mixed with the gelanth.

Genista. *Genista tinctoria*, L. *Dyers' Broom*. *Dyers' Weed*. *Green Weed*. *Wood-Waxen*. *Genet des Teinturiers*, Fr. *Färberginster*, G. (Fam. Leguminosæ).—A low shrub, growing wild in Europe, and sometimes cultivated in this country in gardens. The flowering tops of the plant are employed to dye yellow, whence its name was derived. Both these and the seeds have been used in medicine. They are said to be purgative and even emetic, especially the seeds, which were formerly given as a cathartic in the dose of a drachm and a half (5.8 Gm.). By some authors they are said to be diuretic and to be useful in *dropsy*.

Genoform.—This is stated to be a condensation product of acetyl-salicylic acid and formaldehyde. It occurs as a white powder having a slightly acid taste, which is sparingly soluble in cold water, but freely soluble in alcohol, ether and hot water. It is said to be split up in the intestines into salicylic acid, acetic acid, and formaldehyde. The dose is stated to be five to eight grains (0.32–0.5 Gm.).

Geranium. *Geranium robertianum*, L. *Herb Robert*. *Herbe à Robert*, Fr. *Ruprechtskraut*, G. (Fam. Geraniaceæ).—This species of geranium grows wild both in Europe and the United States, and Pursh states that the American plant is destitute of the heavy odor by which the European is so well known, though the two agree in all other respects. The herb has a disagreeable, bitterish, astringent taste, and imparts its virtues to boiling water. It has been used internally in *intermittent fever*, *consumption*, *hemorrhage*, *nephritic complaints*, *jaundice*, etc., employed as a gargle in *throat affections*, and been applied externally as a resolvent to *swollen breasts* and other *tumors*.

Geum. *Water Avens*. *Radix Caryophyllatæ Aquaticæ*. *Radix Benedictæ Sylvestris*. *Racine*

de Benoitte aquatique (*de Benoitte des Ruisseaux*), Fr. *Sumpfnelkenwurz*, *Wasser-Benedikten-Wurzel*, G.—Several species belonging to this genus have been medicinally employed, but three or four are deserving of particular notice.—*Geum rivale*, L., which once had a place in the U. S. Secondary List, *G. urbanum*, L., formerly recognized by the Dublin College, *G. virginianum*, L., an indigenous species, the root of which has been recommended in *dysentery* by W. A. Gibson (*Med. Rec.*, 1868), and *G. canadense*, Jacq. (*G. album*, Gmel.), recommended by W. A. Spurgeon in *gastric irritation* and *headache*. (*A J. P.*, 1883.)

Geum urbanum, or *avens*, is a native of Europe, where it grows wild in shady places. The root, which is the part used, consists of a short, oblong body, from a quarter to half an inch in thickness, externally brown, internally white towards the circumference and reddish at the centre, and furnished with numerous long descending fibres. When quite dry it is nearly inodorous, but in the recent state has an odor like that of cloves, whence it is sometimes called *radix caryophyllatæ*. The taste is bitterish and astringent. It imparts its virtues to water and alcohol, which it tinges red. Buchner obtained a yellow, amorphous, neutral, bitter-tasting mass, which he calls *geum-bitter*. Distilled with water it yields 0.04 per cent. of a thick, greenish-yellow volatile oil, and gives a pleasant clove-like flavor to the liquid. It contains, besides, according to Trommsdorff, tannic acid, which is abundant, a tasteless resin, gum, bassorin, and lignin. It has been much used in Europe as a tonic and astringent, in chronic and passive *hemorrhages*, *chronic dysentery* and *diarrhæa*, *leucorrhæa*, *intermittent fever*, etc. The dose is from thirty grains to a drachm (2.0–3.9 Gm.) of the powder three or four times a day, or an equivalent quantity in decoction.

Geum rivale, L.—*Water avens* has a perennial, horizontal, jointed, scaly, tapering root, about six inches long, of a reddish-brown color externally, white internally, and furnished with numerous descending yellowish fibres. One or more stems rise from the same root, which also sends up numerous leaves. The stems are about a foot and a half high, simple; erect, pubescent, and of a purplish color. The radical leaves are interruptedly pinnate, with large terminal leaflets, and long, hairy footstalks; those of the stem are petiolate, and divided into three serrate, pointed segments. The flowers are few, solitary, nodding, yellowish purple, and supported on axillary and terminal peduncles. The color of the stems and flowers gives rise to the name of *purple avens*, sometimes applied to the plant. The calyx is inferior, with ten lanceolate, pointed segments, of which the five alternate are smaller than the others. The petals are five, and as long as the calyx. The achenes are oval, with plumose awns, minutely uncinat, and nearly naked at the summit. This species of *Geum* is common to Europe and the United States, though the plant of this country has smaller flowers, with petals more rounded on the top, and leaves more deeply incised than the European. It delights in wet, boggy meadows, and extends from Canada into New England, New York, and Pennsylvania. Its flowers appear in June and July. The dried root is hard, brittle, easily pulverized, reddish or purplish, without odor, and of an astringent, bitterish taste. Boiling water extracts its virtues.

Water avens is tonic and powerfully astringent. It may be used with advantage in *chronic* or *pas-*

sive hemorrhages, leucorrhœa, and diarrhœa, and is said to be beneficially employed in the Eastern States as a popular remedy in the debility of phthisis and in simple dyspepsia. In Europe it is sometimes substituted for the root of *common avens*, or *Geum urbanum*, but is less esteemed. The dose of the powdered root is from twenty grains to a drachm (1.3–3.9 Gm.), to be repeated three times a day. Dose of the decoction (ounce to the pint), one or two fluidounces (30–60 Cc.). A weak decoction is sometimes used by invalids in New England as a substitute for tea and coffee.

Gillenla. *Bowman's Root.* *Indian Physic.* *American Ipecac.* *Racine de Gillénie*, Fr. *Gillenienwurzel*, G.—Under this name the U. S. P. formerly included in its Secondary List the roots of two species of *Porteranthus*, at that time referred to the genus *Gillenla*. (Fam. Rosaceæ.)

P. trifoliatus (L.), Britt. (*Gillenla trifoliata*, Moench.), is an herbaceous plant with a perennial root, consisting of many long, slender, brown branches, proceeding from a thick, tuber-like head. It grows throughout the United States, east of the Alleghany ridge, and, in Pennsylvania, may also be found abundantly west of these mountains. The root should be gathered in September. (See *A. J. P.*, 1898, 501.)

P. stipulatus (Muhl.), Britt. (*G. stipulacea*, Nutt.), is herbaceous and perennial, though much taller and more bushy than the preceding. In the valley of the Mississippi this plant occupies the place of *P. trifoliatus*, which is not found beyond the Muskingum. It grows as far north as the State of New York, extends through Ohio, Indiana, Illinois, and Missouri, and probably into the States south of the Ohio, as it has been found in West Virginia. Its root is precisely similar to that of the Eastern species, and is reputed to possess the same properties.

The dried root of *Gillenla* is not thicker than a quill, wrinkled longitudinally with occasional transverse fissures, and, in the thicker pieces, presenting in some places an irregular, undulated, somewhat knotty appearance, arising from indentations on one side corresponding with prominences on the other. It is externally of a light brown color, and consists of a thick, somewhat reddish, brittle cortical portion, with an interior slender, tougher, whitish, ligneous cord. For microscopic characters, see *G. L. Curry*. (*Am. Pract. and News*, May, 1892.) The bark, which is easily separable, has a bitter, not disagreeable taste; the wood is nearly insipid and comparatively inert, and should be rejected. The powder is of a light brownish color, and possesses a feeble odor, which is scarcely perceptible in the root. The bitterness is extracted by boiling water, which acquires the red color of wine. The root yields its bitterness also to alcohol. By various experimenters it has been shown to contain gum, starch, galloannic acid, fatty matter, wax, resin, coloring matter, albumen, and lignin, besides salts. (*A. J. P.*, xxvi. 490.) *Gillenlin* of W. B. Stanhope was a whitish substance, very bitter, slightly odorous, permanent in the air, soluble in water, alcohol, ether, and the dilute acids, and neutral to test paper. Nitric acid rendered it blood-red, chromic acid green. Tannic acid produced no effect. It gave white precipitates with potassium hydroxide, lead subacetate, and tartar emetic. Half a grain (0.032 Gm.) of it produced nausea and retching. (*A. J. P.*, xxviii. 202.) *G. L. Curry* (*A. J. P.*,

1892, 513), has found two glucosides: the first, *gillein*, obtained from the ethereal extract, formed white feathery crystals, was colored red by sulphuric acid, yellow by nitric acid, and deepened the color of chromic acid; the second, *gillénin*, obtained from the aqueous infusion, was amorphous, of yellowish color, of faint taste at first but becoming very bitter, and giving no color reactions with the acids.

Gillenla is a mild and efficient emetic, and, like most substances belonging to the same class, occasionally acts upon the bowels. In very small doses it has been thought to be tonic, and has been used as a substitute for ipecacuanha, which it is said to resemble in its mode of operation. It was employed by the Indians, and became known as an emetic to the colonists at an early period. Linnaeus was aware of its reputed virtues. Dose, of the powdered root, from twenty to thirty grains (1.3–2.0 Gm.).

Glaucium. *Glaucium flavum*, Crantz. *Yellow Horned Poppy.* *Bruisewort.* *Pavot cornu*, Fr. *Hornmohn*, G. (*Glaucium Glaucium* (L.), Kars., *Chelidonium Glaucium*, L., *G. luteum*, Scop. (Fam. Papaveraceæ).—Fisher separated from this plant two alkaloids, *protopine* and *glaucine* (*A. J. P.*, 1901, 489). Maepmann and Helt recommended the plant in the treatment of diabetes (*Med. Neuigkeiten d. Pharm.-Post*, 1899, 346).

Glechoma. *Glechoma hederacea*, L. *Herba Hederæ Terrestris.* *Lierre terrestre*, Fr. *Gundermann*, *Gundelrebe*, G. *Nepeta Glechoma*, Benth. *Ground-ivy*.—A small perennial, labiate herb, indigenous in Europe and widely naturalized in the United States, and growing in shady, grassy places, as in orchards and along fences and hedges. The herb was formerly official, and still enjoys some credit as a domestic remedy. It has a peculiar, disagreeable odor, and a bitterish, somewhat aromatic taste, and imparts its properties to boiling water. It is very prone to have galls developed on it, and to be infested with certain fungi. (*J. P. C.*, 1875, 127.) It is said to be gently stimulant and tonic, diuretic, and aperient; useful in chronic pulmonary and urinary catarrhs. From a half-drachm to a drachm (2–3.9 Gm.) was usually given in infusion as a dose. A fluidextract made with diluted alcohol would be useful.

Gleditschine.—In 1878 *Gleditschia triacanthos*, L., and *G. ferax*, Desf. (Fam. Leguminosæ), were chemically studied by B. F. Lautenbach (*P. M. T.*, 1878), who abstracted from them an alkaloid, which he found to produce in the frog stupor and loss of reflex activity, due to an action upon the spinal cord. To this alkaloid Lautenbach gave the name of *gleditschine*. In 1887 (*Med. Rec.*, July 31, 1887) Goodman, Seward, and Claiborne brought before the profession, as a local anæsthetic, an alkaloid under the name of *stenocarpine*. Subsequently Claiborne (*Med. Rec.*, Oct. 1, 1887) announced that the tree from which this alkaloid is obtained is the *Gleditschia triacanthos*, and suggested the name of *gleditschine* for it. The alleged alkaloid was placed upon the market in solution, and was largely used as a local anæsthetic and mydriatic by oculists. In October or November, 1888, however, F. W. Thompson of Detroit (*Med. Age*), and T. G. Novy (*Ph. Rund.*) and John Marshall of the University of Pennsylvania (*Phila. Med. News*), published analyses of this solution, showing that it contained 6 per cent. of cocaine, besides some atropine or other mydriatic alkaloid; this *gleditschine* was a fraud. (See also *A. J. P.*, 1887, 589.)

Globularia. *Globularia Alypum*, Delile. (G. *arabica*, Jaub. and Spach.) Wild Senna of Europe. (Fam. Globulariaceæ.)—This is a small shrub, growing on the European shores of the Mediterranean, the leaves of which have been occasionally used as a cathartic since the Middle Ages. Heckel and Schlagdenhauffen obtained from the leaves *globularin*, $C_{15}H_{20}O_8$, an amorphous glucoside which splits by treatment with mineral acids into glucose and *globularetin*. *Globularia vulgaris*, L., was found to contain the same substances. (J. P. C., 1883, 361.) Dose, according to Planchon, one ounce (31 Gm.) in decoction.

Gloriosa. *Gloriosa superba*, L.—The roots, stalk, and leaves of this climbing liliaceous plant are said to be an acrid narcotic poison, and not infrequently used for suicidal purposes in India. C. J. H. Warden found in them two resins, and a very poisonous bitter principle, *superbine*. (P. J., xi, 496.)

Glue.—An impure form of gelatin, obtained from various animal substances by boiling them in water, straining the solution, and evaporating it until upon cooling it assumes the consistence of jelly. The soft mass which results is then divided into thin slices, which are dried in the open air. Glue, when of good quality, is hard and brittle, of a color varying from light yellow to brown, and equally transparent throughout. It softens and swells very much in cold water, without dissolving, but is readily dissolved by hot water. It is soluble in a large proportion of glycerin, and with heat forms with it in smaller proportion a jelly. (Maisch, A. J. P., xlii, 518.) It is employed chiefly for cementing wood.

An elastic and imputrescible preparation of glue may be made by dissolving glue in water by means of a water bath, concentrating the solution, then adding a weight of glycerin nearly equal to that of the glue employed, thoroughly mixing, evaporating the residue of the water, and finally pouring into moulds, or on a marble slab. It is especially applicable to the preparation of artificial anatomical specimens. (J. P. C., 1857, 23.) The various *hæctograph compositions* introduced within recent years for copying purposes are similar mixtures. One of the best copying masses is made by dissolving one part of glue or gelatin in a mixture of two parts of water and four parts of glycerin, with a few drops of phenol, heating, straining, and adding three parts of sifted whiting or terra alba. (See N. R., 1879, 338, 364.) A good *liquid glue* may be made by rubbing up in two pints of rain water, with the heat of a water bath, sixteen ounces of the best white glue and four ounces of dry white lead, until thoroughly mixed, then adding four fluidounces of alcohol, and continuing the heat and the agitation for a few minutes. The mixture is to be poured into bottles while still hot. A liquid glue may also be prepared by mixing in a stoppered bottle 38 parts of glue, properly divided, and 100 parts of acetic acid of commerce, the latter of which dissolves the glue. On exposure the acid evaporates, leaving the glue unchanged. (J. P. C., 3e sér., xvi, 35.) Knapp prepares *strong liquid glue* by covering three parts of good glue, in small pieces, with eight parts of water, and, after it has stood for some hours, adding half a part of hydrochloric acid and three-fourths of a part of zinc sulphate, and exposing the whole for ten or twelve hours to a heat from 81.1° to 87.2° C. (178°–189° F.). This does not gelatinize, and keeps well. (A. J.

P., 1868, 330.) For a *water proof glue* add potassium dichromate to the solution of glue just before using, one part to fifty. (A. J. P., xliii, 420.) *Chromatized gelatin*, obtained by the addition of one part of potassium dichromate to five parts of a solution (5 or 10 per cent.) of gelatin, forms an excellent cement for glass. The surfaces to be united, after being smeared with the cement, are placed upon each other and exposed to the sun. After a few hours the adhesion is perfect and almost invisible, and boiling water itself has no action on the cement. (L. L., Nov. 11, 1876.) For other formulas for liquid glue, see A. J. P., xliii, 421.

Glutoid Capsules.—Gelatin capsules which have been hardened by exposure to formaldehyde are recommended by Sahli in three grades, the weak capsule capable of withstanding the action of the gastric juices for from one and a half to seven hours, the strong for twelve hours. They appear to have great therapeutic value for the purpose of conveying intestinal antiseptics, medicinal substances which are destroyed by the peptic secretions, and irritating drugs through the stomach into the intestines. They have been used by Sahli (D. A. K. M., lxi) for diagnostic purposes. By their means he asserts that he is able to determine the condition of the pancreatic secretion and the closure of the pancreatic duct, the varieties of jaundice, etc.

Glutol (*Glutiform*) is made by the action of the solution of formaldehyde upon gelatin. It is a hard, clear, transparent mass, which may be pulverized.

Glybolid. *Glybrid*.—A preparation, of the consistence of a paste, made by combining 1 part of boric acid, 1 part of acetanilide and 2 parts of glycerin. Used as an antiseptic in *pustules*, *abscesses*.

Glycerinophosphoric Acid. *Acidum Glycerinophosphoricum*. $C_3H_5 = \frac{O.P.O_3H_2}{(OH)_2}$. This is an oily liquid whose salts have been commended as powerful nerve tonics in *neurasthenia* and allied conditions. The 25 per cent. sterilized solution of the sodium salt given hypodermically, in dose of fifteen minims (0.9 Cc.), increased to one fluidrachm (3.75 Cc.), has been especially used in *sciatica*. The iron salt has been used in *chlorosis*. (K. T. W., 198.)

Glycogenal.—This substance, which is said to be closely allied to glycogen, is obtained from the animal system and occurs as a whitish, tasteless, odorless powder, freely soluble in alcohol and ether, and has been brought forward by Roerig as a specific remedy in *tuberculosis*, *puerperal fever*, *typhoid fever*, other infectious diseases, and also in *lupus*, and even in *cancer*. Applied hypodermically it is affirmed also to cure *Basedow's disease*, *migraine*, *catarrhs*, etc. It is said that although one and one-half ounces (46.5 Gm.) may be taken daily with safety, one-third of a grain (0.021 Gm.) given hypodermically acts powerfully and is a sufficient dose if administered every three hours in *typhoid fever*. The substance has probably little value. (M. R., 1900 and 1901.)

Glycosal. *Monosalicylic Glycerinester*. $C_3H_5(OH)_2.C_7H_5O_2$.—This substance, originally prepared by E. Tauber, is a white crystalline powder, soluble (one per cent.) in cold water and freely in hot water, very soluble in alcohol, decomposed by alkalis and alkali carbonates, and also, it is said, by the intestinal juices with the separation of salicylic acid.

Glycosal has been especially recommended as affording means of treating *rheumatism* by external application. Zeigan (*B. K. W.*, 1903) found that from 50 to 100 grammes of its twenty per cent. alcoholic solution, to which a little glycerin had been added, placed upon the rheumatic part and covered with waterproof wadding, was sufficient to produce in four or five hours strong sweating lasting from a half to two hours, and in from six to eight hours a notable elimination of salicylic acid with the urine with the relief of the local symptoms. Ratz, however, has been unable to secure absorption either by means of the alcoholic solution or yet by inunctions made with an indifferent fatty basis; although when ether, oil of turpentine, or chloroform was added in the proportion of fifteen per cent. to the ointment, a notable proportion of salicylic acid appears in the urine after the local application. R. Block (*Th. M.*, Sept. 1903) found that the best method of using glycosal is a twenty per cent. collodion, which he applied every two to four hours to swollen rheumatic joints with asserted most extraordinary results. He claimed that if no relief is afforded the inflammation may be positively considered not to be of rheumatic origin.

Glycosal is also used internally as an anti-rheumatic in doses of one hundred and fifty to one hundred and eighty grains (9.8–11.6 Gm.) a day, usually without the production of salicylism; eight to ten grains (0.5 to 0.65 Gm.) may be given every half to three hours until sweating is induced. The remedy is probably very uncertain and feeble in its influence.

Glycozone.—A thick syrupy liquid, said to be a stable chemical compound, produced by treating chemically pure glycerin with ozone until it is saturated. It is claimed to be of benefit in relieving *catarrhal* and inflammatory conditions of the stomach when given in teaspoonful (3.75 Cc.) doses. It is also of value in stimulating healthy granulation in *ulcers*, when applied locally.

Gnaphalium. *Gnaphalium margaritaceum*, L. (More correctly *Anaphalis margaritacea* (L.), Benth. and Hook.) *Cudweed*. *Life-everlasting*. *Pied de Chat*, *Immortelle*, Fr. *Katzenpfötchen*, *Immerschön*, G. (Fam. Compositae).—An indigenous herbaceous perennial, which with *G. obtusifolium*, L. (*G. polycephalum*, Michx.), or *sweet-scented life-everlasting*, is sometimes used in the form of tea in intestinal and pulmonary *catarrhs*, and, externally, in the way of fomentation, in *bruises*, but it probably possesses little medicinal virtue. In Europe different species of *Gnaphalium* are occasionally employed for similar purposes.

Gold.—The chief preparations of gold which have been employed in medicine are metallic gold in a finely divided state, the oxide (trioxide, incorrectly called auric acid), the chloride (trichloride), the iodide, the double gold and sodium chloride, now official, the ammonium chloraurate (a compound of gold trichloride and ammonium chloride), and the gold cyanide (tricyanide). Aqueous solutions of gold in the *colloidal* state have been prepared by Bredig by forming an electric arc under water with gold wires. The sparking between gold electrodes liberates finely divided gold which dissolves with bluish-red color. The addition of acids and certain salts coagulates this colloidal gold solution; the addition of gelatine prevents this coagulation. *Gold in powder* may be obtained by rubbing up gold leaf with ten or twelve times its weight of potassium sulphate

until brilliant particles are no longer visible, and then dissolving away the sulphate with boiling water. The *chloride* is obtained by dissolving pure gold in three times its weight of nitrohydrochloric acid, with the aid of moderate heat. The solution is evaporated by a gentle heat nearly to dryness, being at the same time stirred with a glass rod. It is in the form of a crystalline mass of a deep red color. Its solution has a fine yellow tint. Being deliquescent, it requires to be kept in ground-stoppered bottles. (See *Auri et Sodii Chloridum*.) The *iodide* may be made by precipitating a solution of gold trichloride by one of potassium iodide, and washing the precipitate with alcohol to remove the excess of iodine. It is of a greenish-yellow color, and, when heated in a porcelain crucible, is resolved into iodine vapors and a residue of pure gold. The *ammonium chloraurate* is formed by dissolving one part of the gold trichloride and two parts of ammonium chloride in distilled water, assisted by a few drops of nitrohydrochloric acid, and evaporating the solution to dryness by a gentle heat. The *cyanide* is best obtained, according to Oscar Figuier, as follows: Prepare the gold chloride as neutral as possible by repeated solutions and crystallizations; and to the solution of this salt add, very cautiously, avoiding any excess, a solution of pure potassium cyanide, so long as any precipitate falls. (See *Potassii Cyanidum*.) The precipitate, consisting of gold cyanide, is to be washed with pure water, and dried in the dark. Gold in powder, and the oxide, chloride, iodide, sodio-chloride, and cyanide, are official in the French Codex.

The preparations of gold are decidedly poisonous, though in different degrees. The chloride is most virulent, and, according to Chrestien, is even more active than corrosive sublimate. In an overdose, it produces pain, inflammation, and even ulceration of the stomach and bowels, and otherwise acts as a corrosive poison. It is said that these preparations, in moderate doses, produce increased fulness and frequency of the pulse, and augment the urine and insensible perspiration, without interfering with the appetite or the regular action of the bowels, but, if the dose be pushed too far, general irritation is apt to be produced, inflammation seizes upon some organ, according to the predisposition of the individual, and fever is developed.

Gold in powder, the oxide, chloride, and iodide are not as much used as the soluble gold and sodium chloride. The oxide may be given in the form of pill, containing the tenth of a grain (0.006 Gm.), in *scrofula* and *lymphatic swellings*, beginning with one pill daily, and afterwards gradually increasing to seven or eight in twenty-four hours. The chloride has been used with advantage as a caustic in *lupus*, and in *sypilitic tubercles* and *ulcers*, by Chavannes. The iodide may be given in the same cases with the other preparations. The *dose* is from the fifteenth to the tenth of a grain (0.004–0.006 Gm.).

In 1839 Goubert asserted before the French Academy that gold bromide, administered in a weak solution, is more efficacious and durable in its action in *epilepsy* than are any of the other bromides, and is also better tolerated. This statement led Shtcherbak to study the effect of the gold bromide upon the motor area of the cerebral cortex, according to the method of Albertoni. He found that in the dose of from one-half to three grains per kilogramme of weight it so depressed the cortical motor centres that even the strongest

electric stimulation failed to bring about any epileptic seizures. It is further asserted that the gold bromide never causes in man general depression, languor, emaciation, or other pronounced symptoms of bromism. The amount of bromine in the bromide, 55 per cent. by weight, would seem too small to make it probable that the bromine is the active ingredient of the salt. The dose of the bromide for the adult is from one-eighth to one-fifth grain (0.008–0.012 Gm.); for children, one-twentieth to one-tenth grain (0.003–0.006 Gm.). As a substitute for this preparation, E. Merck has proposed *gold and potassium bromide* (*Aurum-Kalium bromatum*, $\text{AuBr}_3 \cdot \text{KBr} + 2\text{H}_2\text{O}$), which has been tested by I. Jankura and Laufenauer (*Pest. Med. Chirurg. Presse*, 1892), and found to be a valuable anti-epileptic. It may be used hypodermically, by dissolving 2 parts of the salt in 100 parts of distilled water, and injecting of this eight minims (0.5 Cc.) and increasing the dose to thirty-two minims (2 Cc.). Solutions of gold pentabromide or pentachloride, recognized by their deep red color, are offered by several manufacturers under proprietary names, and advertised to produce remarkable effects in *anæmia*, *diabetes*, and in various dyscrasias.

Ammonium chloraurate has been recommended by Bouchardat in *amenorrhœa* and *dysmenorrhœa* in debilitated subjects, in the dose of about the tenth of a grain (0.006 Gm.). A grain may be dissolved in five teaspoonfuls of alcohol and five of water, and a teaspoonful given morning and evening, mixed with sweetened water.

Gold cyanide is employed, like the gold and sodium chloride, mixed with inert powders by friction, and in the form of pill. The fifteenth of a grain (0.004 Gm.) may be rubbed into the gums daily for fifteen days, next, the fourteenth of a grain for fourteen days, and so on, increasing until the dose amounts to the ninth or eighth of a grain (0.0075 or 0.008 Gm.). The dose for internal exhibition is the eighteenth of a grain, gradually increased to the eighth (0.0038–0.008 Gm.). Gold cyanide has been found useful in the treatment of *syphilis* and *scrofula* by Pourché, and is said to be less irritating than the double chloride.

The different medicinal compounds of gold should not be prepared in pill, powder, or otherwise until they are wanted for use, as they are liable to undergo decomposition when kept. They should be carefully secluded from the light.

Gold salts of various alkaloids have been prepared by H. A. D. Jowett (*Trans. Chem. Soc.*, 1897), but up to the present have not been tested physiologically.

Gomabrea.—This is an exudation from a Chilean tree, which has been offered in large quantities in France as a substitute for gum arabic, and is said to be of practical value.

Gratiola. *Gratiola officinalis*, L. *Hedge-hyssop*. *Gratiola*, Fr. *Gnadenkraut*, *Gottesgnadenkraut*, G. (Fam. Scrophulariaceæ).—This is a perennial herb, indigenous in the south of Europe, in meadows and other moist grounds. The whole herb is used. It is nearly inodorous, but has a bitter nauseous taste. The indigenous *G. virginiana*, L. (*G. carolinensis*, Pers.), closely resembles the European plant and indeed was regarded by Michaux as identical with it. Both water and alcohol extract its active properties. F. G. Walz found in it the following constituents: 1, *gratiolin*; 2, *gratiosolin*; 3, *gratiolonic acid*; 4, *gratiola fat*; and 5, a brown resin. (For chemistry see *P. J.*, vol. lxxix. 295, and vol. lxx. 385.) The *gratiolin* is de-

composed on prolonged boiling with diluted H_2SO_4 into *gratiololin*, *gratioloretin*, and sugar; the *gratiosolin* is similarly decomposed by dilute acids or alkalies into *gratiosolein* and sugar; the *gratiolonic acid* is obtained in the form of pearly white scales of a fatty odor. Hedge hyssop is a drastic cathartic and emetic, possessing also diuretic properties, and has been used in Europe for the relief of *dropsy*, *jaundice*, *worms*, *chronic hepatic affections*, and *scrofula*. The dose of the powdered herb is from fifteen to thirty grains (1.0–2.0 Gm.); of the infusion (half an ounce to the pint of boiling water), half a fluidounce (15 Cc.).

Ground Nuts. *Peanuts*. *Goobers-nuts*.—The fruit of *Arachis hypogæa*, L., a leguminous, annual plant, indigenous probably in Africa and South America, and abundantly cultivated in our Southern States, China, etc. Thirty thousand tons are said to be produced annually in Senegal, while the export from Madras in a single year amounts to one hundred thousand tons of the nuts (known there as *pistaches*), besides large quantities of the oil; the present annual product of Virginia and North Carolina is over two million bushels. A remarkable property of the plant is that its fruit ripens under the surface of the ground, into which the pods penetrate in the progress of their growth. The beans or seeds contain about 45 per cent. of a fixed oil.

OLEUM ARACHIS, Br. *Add.*, *Peanut Oil*, consists of the glycerides of four different fatty acids. The chief of these is oleic acid, $\text{C}_{18}\text{H}_{34}\text{O}_2$, with which are associated *hypogæic acid*, $\text{C}_{16}\text{H}_{30}\text{O}_2$, *arachidic acid*, $\text{C}_{20}\text{H}_{40}\text{O}_2$, and *lignoceric acid*, $\text{C}_{24}\text{H}_{48}\text{O}_2$. It should be obtained by expression without heat. It is usually of a pale yellowish or green color with a faint odor, and a more distinct taste of the nuts, although on rectification a nearly colorless and tasteless oil may be obtained. Upon exposure to the air the oil slowly thickens and becomes rancid. It is soluble in all proportions in ether, chloroform, and petroleum benzin, but insoluble in alcohol. Its sp. gr. is 0.918 at 15.6° C. (60° F.). At 3.3° C. (38° F.) it thickens, solidifies at about –5° C. (–23° F.), and at 326.6° C. (620° F.) is decomposed, giving out spontaneously inflammable vapors. Winter made experiments to ascertain how far it might be employed with advantage in pharmacy, and found that it answered well in the preparation of cerates and ointments, but would not serve as a substitute for olive oil in the preparation of lead plaster. (See *Proc. A. Ph. A.*, 1897, 179, for later views on the subject.) It is a non-drying oil, and therefore will not answer for painting; but it is enormously used for adulteration (particularly of French olive oils) and for various purposes in the arts, as for lubricating machinery, and in the manufacture of woollen cloths; in lamps it burns with a bright light. It saponifies slowly, but yields an excellent firm, white, and odorless soap.

Guacamol. *Camphoric Guaiacolester*. $\text{C}_8\text{H}_{14}(\text{COO} \cdot \text{C}_8\text{H}_4\text{OCH}_3)_2$.—This is a white, tasteless powder, insoluble in water or gastric juice, easily soluble in hot alcohol and chloroform, and believed to be decomposed by the intestinal alkalies into camphoric acid and guaiacol. It was originally brought forward by Lasker as an antihidrotic, and has been used in *phthisis* by other clinicians for arresting the *night sweat* with asserted excellent results. Dose, three to fifteen grains (0.2–1 Gm.), taken immediately after supper in capsule.

Guaco.—This name is given in Central and South America and the West Indies to various

plants belonging to the genera Willughbæa (better known under the newer name, Mikania) and Aristolochia; but it is in its application to the different species of the former genus that the name is known in medicine. The species most used is *M. amara* (Willd.), O. Kze., *Mikania amara* (Willd.), *M. Guaco* (Humb. and Bonpl.). The plants are closely allied to the Eupatoria. *M. Houstonis* (Willd.), O. Kze., *M. gonoclada* (DC.), O. Kze. (of the Fam. Compositæ); *Aristolochia fragrantissima*, Ruiz, *A. grandiflora*, Sw., *A. pentandra*, Jacq. (of the Fam. Aristolochiaceæ); *Comocladia integrifolia*, Jacq. (Fam. Anacardiaceæ), are all known locally as guaco. *M. amara* is described as having twining stems, with round, sulcate, and hairy branches; ovate subacuminate, remotely dentate leaves, somewhat narrowed at the base, rough above and hairy beneath, and flowers in opposite axillary corymbs. The plant is a native of intertropical America, and has been introduced into the West India Islands from the continent. The leaves are the part used. The result of a long and close investigation into the natural history of guaco by the distinguished Guibourt is, that the guaco from this source, instead of possessing, as has been asserted, a strong, penetrating, and nauseous odor, is in fact inodorous, and destitute of all active properties, and that the strongly aromatic plants which have been employed under the name of guaco all belong to the genus Aristolochia, especially *A. cymbifera*, Mart. and Zucc., growing in Brazil, after this *A. maxima* (De Cand.), and in less degree *A. maxima*, Jacq. (*A. geminiflora*, H. B. K.). (*J. P. C.*, 1867, 99.)

Although the guacos of South America seem to be entirely distinct drugs, they appear to be indiscriminately used by the natives for the cure of the bites of poisonous serpents, as was first made known by Mutis, and afterwards confirmed by Humboldt and Bonpland. The medicine is also used in South America as a febrifuge and anthelmintic, and has been considered antisyphilitic. A few years ago it attracted on the continent of Europe considerable attention on account of its alleged power in epidemic cholera and chronic diarrhæa. The *Aristolochia cymbifera*, Mart. and Zucc., has been the subject of a careful study by L. Butte. The root of this plant as it occurs in commerce is cylindrical, from three to four centimeters in diameter, much broken up into long rootlets, yellowish, with a strong odor, especially in the bark. The plant itself is a vine, growing in great abundance in the province of Tabasco in Mexico. Butte was not able to find in it either an alkaloid or a glucoside, but he found a blackish resin which may be the active principle of the plant, though this does not seem probable, since Butte found the alcoholic extract much less active than the aqueous extract, which would hardly be the case if the resin were really the active principle. In the physiological experiments made with the aqueous extract it was found that in the guinea pig and rabbit massive doses produced cries and excitement, followed after a time by sleep, with muscular relaxation and diarrhæa. In the dog vomiting and diarrhæa were very marked. The muscular relaxation was probably centric, as the motor nerves and muscles were in a condition of activity. An apparent loss of function in the sensory nerve trunks Butte believed to be due not to paralysis of the nerve fibres, but of the centres of sensation. Although the muscle was not completely paralyzed, careful experimen-

tation showed that its contractility was less than the norm after death from the poisoning. Death was produced by an arrest of the respiration. The heart continued to beat both in the reptile and the mammal after the cessation of respiration; nevertheless there was depression of the arterial pressure, apparently due to the action of the drug upon the heart. After death marked signs of gastro-intestinal irritation were found, the medicine having been given by the mouth. During life the urine was albuminous, and at the autopsy the kidneys were found congested. The temperature gradually rose during the poisoning, and less glucose than normal was found in the blood. Butte believes that guaco has valuable therapeutic properties in the treatment of skin affections, especially eczema and pruriginous maladies, in which he used it both locally and internally. He gives the dose of the aqueous extract of guaco as three grains (0.2 Gm.) three times a day. In the external application the following formula was used. Guaco (bruised), 30 parts; sodium bicarbonate, 5 parts; water, 1000 parts; boil for a quarter of an hour, allow to macerate one hour, decant, and use the liquid as a lotion. (*Annales de la Policlin. de Paris*, Sept. 1890.) Guaco is said to be largely used in South America as an antirheumatic, and E. W. Pritchard (*P. J.*, 1861) affirms that in the *gouty paroxysms* it is especially effective given in the dose of a fluidrachm (3.75 Cc.) of the tincture every four hours, and applied locally.

Guaiacol Compounds and Derivatives.—A very large number of these compounds have been produced by pharmaceutical chemists and put upon the market as substitutes for and improvements on ordinary guaiacol. Few of them have any more therapeutic value than guaiacol and most of them are less effective. In regard to their manufacture we refer the reader to elaborate papers by F. G. Ehlert (*Ph. Rev.*, 1901 and 1902).

Guacamphol.—This camphoric ester of guaiacol is a white, tasteless, insoluble powder, which is asserted to be broken up in the intestines into camphoric acid and guaiacol. It has been especially recommended as a remedy of great value in the treatment of the *night sweats of phthisis*. In some cases it is necessary to be administered for one or even two weeks for the desired effect. Dose, three to fifteen grains (0.2-1 Gm.) exhibited two hours before bed time.

Guaethol, a methyl derivative of guaiacol, soluble in ether and alcohol but very slightly so in water. It is said to be medicinally equivalent to guaiacol except that it acts more promptly. Dose, two to four grains (0.13-0.26 Gm.).

Guaiacol Benzyl Ether or **Pyrocain** occurs in colorless crystals, soluble in ether and melting at 62° C. It possesses the general therapeutic properties of guaiacol.

Guaiacol Biniodide, a reddish-brown powder, with something of the iodine odor, soluble in alcohol and fatty oils, has been proposed by Vicario as a local application in tuberculosis.

Guaiacol Bisulphonate of Quinine or **Guaiacuin**. ($C_9H_4O_2CH_3HSO_3$) $_2$ $2C_{20}H_{24}N_2O_2$.—Guaiacuin is an acid salt, occurring as a yellowish crystalline powder, very soluble in water, alcohol, and dilute acids, and of a bitter taste. It contains 44.26 per cent. of alkaloid quinine, combined with 55.74 per cent. of guaiacol sulphonic acid, the latter being equivalent to 33.38 per cent. of pure guaiacol. It has been brought forward as an anti-malarial remedy and a gastro-intestinal stimulant and antiseptic.

Dose, as a tonic, from three to six grains (0.2–0.4 Gm.); as an antiperiodic, ten grains (0.65 Gm.) three times a day.

Guaiacol Cinnamate or **Styracol** occurs in white, odorless, tasteless, stable needles, almost insoluble in water, readily soluble in alcohol, chloroform, acetone and benzene. It is said when taken internally to be broken up in the intestines into cinnamic acid and guaiacol and to be useful not only in *phthisis* but in various chronic *gastro-intestinal* and *genito-urinary catarrhs*. **Dose**, fifteen grains (1 Gm.), three or four times a day.

Guaiacol Ethyl is an oily liquid of an agreeable aromatic odor, soluble in water, which was brought forward as a remedy in *tuberculosis*, with the statement that it acts upon the human system like guaiacol, but more quickly and energetically. The researches of De Buck (*Belg. Méd.*, 1897) indicate, however, that it is not more effective than is guaiacol in tubercular diseases. It is affirmed, however, to be a pronounced analgesic, which when applied to the skin by means of a brush is rapidly absorbed, and in cases of *neuralgia* or *neuritis* produces great relief. It may also be used subcutaneously in 10 per cent. emulsions with sterilized glycerin, and has been so applied; this glycerin solution has also been used in *cystitis*.

Guaiacol Iodoform is a reddish-brown syrupy liquid, which is really a solution of iodoform in guaiacol. It has been used hypodermically for *tuberculosis* (one part diluted with sixteen parts of olive oil) in doses of fifty minims (3.1 Cc.).

Guaiacol Phosphate.—Phosphoric Guaiacol-ether has been shown by A. Gilbert (*S. M.*, 1897) to be split up in the intestines, with the liberation of its constituents, and to afford, therefore, a method of administering guaiacol, over which it has the advantage of being innocuous to the mucous membrane of the stomach. It would appear, however, much less active and much more uncertain in its influence than is guaiacol.

Guaiacol Phosphate. **Phoso-Guaiacol**. $P(OC_6H_4OCH_3)_3$. **Phospho-guaiacol**.—Phosphate of *Guaiacyl-ether* is a white crystalline powder, possessing a sharp taste and indifferent odor. It is soluble in water, dissolves very freely in alcohol, ether, chloroform, acetone, benzene, toluol, and the fatty oils, but it is sparingly soluble in oil of turpentine and in glycerin. Melting point, 77.5° C. It contains 92.25 per cent. of guaiacol, and was introduced in 1897 by Ballard. (*Rép. de Pharm.*, 1897.) It is but slightly poisonous, and probably is capable of acting as do other preparations of guaiacol.

Guaiacol Salol occurs in small odorless, tasteless, colorless crystals, readily soluble in alcohol, ether, chloroform or benzene, melting at 65° C. It is said to be split up into its constituents in the intestines and has been used in *phthisis* and as an *intestinal antiseptic*. **Dose**, ten to fifteen grains (0.65 to 1 Gm.) a day.

Guaiacol Succinate.—This drug occurs in fine, silky, white crystals insoluble in water, slightly so in alcohol and ether, very soluble in chloroform or acetone, and melting at 136° C. It is said to act medicinally like guaiacol.

Guaiacol Valerate. **Geosote**.—This occurs as a pale yellow, oily, mobile liquid, insoluble in water, freely soluble in alcohol, ether, and benzene. Sp. gr. 1.038, boiling point variously given from 240° to 260° C. Geosote is used in *phthisis* and as a *gastro-intestinal antiseptic* in fermentative *dyspepsia* and *diarrhœa*. **Dose**, five to ten grains (0.32–0.65 Gm.).

Guaiaciform. **Geoform**. **Methylenediguaiacol**.—The drug is a tasteless yellow powder, odorless at first but acquiring a vanilla-like odor, soluble in alcohol or ether but insoluble in water. It is affirmed to contain 95.38 per cent. of guaiacol and to be non-irritating and non-toxic.

Pyrocain. **Brenzain**.—The benzyl ester of guaiacol is a colorless, tasteless, odorless, stable body, which is affirmed to act like guaiacol and to be free from irritating, nauseating and toxic properties. Used in the same doses as guaiacol.

Guaiacyl. **Gajacyl**. **Calcium Ortho-guaiacol Sulphonate**. $(C_6H_3(OH).(OCH_3)SO_3)_2Ca$.—This is a powder of a bluish-gray color, soluble in water and in alcohol. The aqueous five per cent. solution has a violet red color and may be used hypodermically in quantities of eight to twenty minims (0.5–1.3 Cc.).

Guaialin. **Methylene Diguaiacol Benzoic Ester**. This substance occurs in an amorphous powder, of a pea-green color, said to contain 60 per cent. of guaiacol, 30 per cent. of benzoic acid, and 7 per cent. of formaldehyde. It is recommended as an antipyretic and alterative tonic in *tuberculosis*.

Guaiaeprol. **Piperidin Guaiacolate**.—This salt occurs in colorless crystals, melting at 79°–80° C. (174.2°–176° F.), having a feeble creosote odor, soluble in water 1 to 30, freely soluble in alcohol, and has been used to a moderate extent. (*B. M. J.*, vol. ii. 1898.) In doses of from five to ten grains (0.32–0.65 Gm.) in capsules, three times a day, after meals, in *phthisis* it is said to lessen cough and cause general improvement.

Guaiaquin. **Quinine Guaiacol Bisulphonate**. $(C_6H_4O_2CH_3HSO_3)_2C_{20}H_{24}N_2O_2$.—This substance occurs as a yellowish crystalline bitter powder, very soluble in water, alcohol and diluted acids. It has been used to some extent in internal medicine as a tonic, but especially as an antiperiodic in various *malarial diseases* with asserted good results. It is stated that the sterilized 10 per cent. solution may be given hypodermically with the production of little pain. This solution has also been used locally with alleged good results in *gonorrhœa* and other infected conditions. **Dose**, three to ten grains (0.2–0.65 Gm.); sixty grains (3.9 Gm.) may be given in a day.

Guaiaquinol. **Guaiaquinol**. **Quinine Dibromoguaiacolate**.—This is a compound which combines the properties of quinine, guaiacol, and bromine. It is freely soluble in water and is used as an antipyretic and sedative in *tuberculosis*. **Dose**, eight to fifteen grains (0.5–1.0 Gm.).

Guaiasanol. **Diethyl-glycocolguaiacol Hydrochloride**. $C_6H_4 \begin{matrix} \diagup OCH_3 \\ \diagdown O.CO.CH_2N.(C_2H_5)_2.HCl \end{matrix}$ This substance occurs in very soluble white prisms fusing at 184° C. (363.2° F.), emitting an odor faintly suggestive of guaiacol and possessing an acrid taste. It was first produced by Einhorn and Hutz (*J. P. C.*, 174, 1903) through the union of aceticomonochlorguaiacol and diethylamine. In the presence of alkalis it breaks up, liberating guaiacol, which has been found in the urine of animals to which guaiasanol had been given. It has been given by A. Einhorn in doses of forty-five to one hundred and eighty-five grains (3–12 Gm.) daily as a substitute for guaiacol.

Guaisotol.—This is one of the numerous class of preparations having a name which suggests that of a chemical compound; it is stated to be a *syrup of guaiacol* containing 16 grains of guaiacol to the fluidounce. **Dose**, one to four fluidrachms (3.75–15.00 Cc.).

Guajamar. *Guaiacol-glycerinester*.—This is a white crystalline powder, $C_6H_4 \begin{smallmatrix} OCH_3 \\ \diagup \\ OC_6H_7O_2 \end{smallmatrix}$, which possesses a bitter aromatic taste, melts at 75° C. (167° F.) and dissolves in alcohol, ether, glycerin and 20 parts of water at the ordinary temperature. According to G. Buttler it splits up in the intestines into guaiacol and glycerin and affords an excellent method of intestinal antiseptics in *typhoid fever*, *diarrhoea*, etc. Great relief has been obtained in *acute and articular rheumatism* by the local application of the remedy in the form of an ointment consisting of two parts of guajamar and one of lanolin. *Dose*, three to fifteen grains (0.2–1 Gm.).

Guano. *Bird-manure*.—This is a valuable manure, consisting of the decomposed excrement of countless aquatic birds, which has accumulated for ages on certain barren and uninhabited islets of the western coast of South America and in other localities throughout the world. Guano is a coarse dry powder of a brown color. Exposed to the air it absorbs moisture, and becomes somewhat sticky. Its odor is offensive and slightly ammoniacal. With the powder are intermingled friable lumps, which exhibit in their inside whitish specks, and which, when exposed to the air, fall to powder, exhaling an ammoniacal odor. It is soluble in great part in water, and the solution formed contains chiefly ammonium oxalate. When exposed to heat it blackens, burns with a slight flame, exhales the odor of ammonia, and leaves a whitish ash, varying in amount from 27 to 35 per cent. The value of guano as a fertilizer depends chiefly upon the proportion of the organic ingredients, the phosphates being of secondary importance. M. E. Baudrimont infers, from the analyses of seventeen samples of Peruvian guano, that the proportion of nitrogen may be obtained approximately by dividing the amount of the organic matters by five. The samples varied greatly in value. (*J. P. C.*, Oct. 1857.) Crystals of ammonium carbonate have frequently been observed in guano. C. Morfit of Baltimore found Colombian guano to be rich in phosphoric acid and lime. (*Chem. Gaz.*, Dec. 1, 1855.) Unger obtained from Peruvian guano, in 1845, a peculiar substance, called *guanine*, $C_5H_5N_5O$. (See *J. P. C.*, 4e sér., xvii. 328.) By the oxidation of guanine, as well as by other processes, chemists have prepared *guanidin*, CH_5N_3 , and from this in turn a series of derivatives. For an elaborate investigation of the chemistry and physiological action of these substances, see *Arbeiten des Pharmak. Inst. zu Dorpat*, Bd. vii.–xii. By the action of nitrous acid upon guanine there is produced the base *xanthine*, $C_8H_4N_4O_2$, and Emil Fischer has shown that *theobromine* and *caffeine* are capable of being produced from xanthine, and are, in fact, dimethyl- and trimethyl-xanthine respectively. (*A. J. P.*, 1882, 218.) Guano is a powerful local irritant, which, when mixed with equal parts of potters' clay or other diluent, is capable of causing vesication. It has been used as a counter-irritant and also as a stimulant in certain *cutaneous diseases*, especially in *eczema*, *eczyma*, and *tinea capitis*. For various preparations of guano, see 16th ed. *U. S. D.*

Guarea. *Guarea purgans*. *Gito*. (Fam. Meliaceae.)—The root of *G. Rusbyi* (Brit.), Rusby (*Syncarpus Rusbyi*, Brit.), of Bolivia, has properties resembling those of ipecac. The root and bark of this Brazilian plant are said to be drastic purgatives.

Gum Cebil.—This gum is a product of the Brazilian leguminous tree *Piptadenia Cebil*, Griseb. (*Cebil colorado*). It occurs in reddish-yellow tears, or in dark-colored angular masses, and forms a reddish-yellow, odorless, viscous mucilage of acid reaction. It is said to contain 80.73 per cent. of arabin.

Gum, Cedar.—This, the product from *Oedraa australis*, F. Muell., or *Red Cedar* of Queensland (Fam. Meliaceae), is a very pale yellow gum, occurring in tears about an inch long, feeling leathery between the teeth, swelling and, finally, almost dissolving in water. It contains about 68 per cent. of arabin, and 6 per cent. of metarabin, but no resin. (*P. J.*, vol. xx. 1890.)

Gum Elemi. *Elemi*. *Elemi*, Fr.—The botanical source of this concrete resinous exudation is not positively determined, and it is, indeed, probable that the drug usually known by the name of *elemi* is derived from several different trees. That known to the ancients is said to have been obtained from Ethiopia, and all the elemi of commerce was originally brought from the Levant. The tree which afforded it was not accurately known, but was supposed to be a species of *Amyris*. At present the drug is said to be derived from three sources,—namely, Brazil, Mexico, and Manila. According to Peckolt, *Brazilian elemi* (*Tacamahaca*, *Tacamaque terreuse*, Fr.) appears to be the product of *Protium heptaphyllum* (Aubl.), March (*Icica heptaphylla*, Aubl.), *P. Icicariba* (DC.), March (*Icica Icicariba*, DC.) (Fam. Burseraceae), and other species of the genus. It seems not to occur to any extent in general commerce, and to be used locally as a substitute for incense. It occurs in brown almost odorless pieces, internally white, about the size of a bean. *Manila elemi* occurs in two forms, one soft and one hard, and is believed to be the product of *Canarium commune*, L., of the same family. It is erroneously stated in some works to be a native of Carolina. The elemi is obtained by incisions into the trees, through which the juice flows and concretes upon the bark. The *Mexico elemi* is said by Royle to be obtained from a species of *Elaphrium* which that author has described from dried specimens and proposes to name *E. elemiferum*. (*Mat. Med.*, Am. ed. 330.)

Carana-elemi.—The product of *Protium Carana*, (H. B. K.), March, produced on the confines of Venezuela and Colombia, occurs in masses of a greenish-yellow color, externally hard, internally soft, with a peculiar fennel-like aromatic odor. It is insoluble in water, soluble in sulphuric ether, chloroform, and benzene. According to Tschirch and Saal, carana-elemi contains 20 per cent. of exceedingly acrid resin. (*A. Pharm.*, Bd. 241, 1903.)

Elemi is in masses of various consistence, sometimes solid and heavy like wax, sometimes light and porous; unctuous to the touch; diaphanous; of diversified colors, generally greenish with intermingled points of white or yellow, sometimes greenish white with brown stains, sometimes yellow like sulphur; fragile and friable when cold; softening by the heat of the hand; of a terebinthinate somewhat aromatic odor, diminishing with age, and resembling to some extent that of lemon and fennel; of a warm, slightly bitter, disagreeable taste; entirely soluble, with the exception of impurities, in boiling alcohol; and affording a volatile oil by distillation. "Moistened with rectified spirit, it breaks up into small particles, which, when examined by the microscope, are seen

partly to consist of acicular crystals." Br. 1885. Elemi is sometimes adulterated with rosin and turpentine.

The two varieties of elemi that have been investigated chemically are the Manila, or soft elemi, and the Brazilian, or hard elemi. The Manila elemi contains 10 per cent. of an *etheral oil* (made up of phellandrene and dipentene), *amyrrin*, $C_{30}H_{50}O$, of which, according to Vesterberg, the isomeric varieties *a* and *b*-*amyrrin* are present, an *amorphous resin*, small amounts of *elemic acid*, $C_{35}H_{46}O_4$, *bryoidin*, $C_{20}H_{38}O_3$, and a bitter principle. The Brazilian elemi (*protium elemi*) contained *protomyrrin*, 30 per cent.; *protolaminic acid*, 25 per cent.; and *protolaresine*, 37.5 per cent. The *protomyrrin* has the same melting point and formula as the *amyrrin* from Manila elemi.

Elemi has properties analogous to those of the turpentine, but is exclusively applied to external use. In the United States it is rarely employed even in this way. In the pharmacy of Europe it enters into the composition of numerous plasters and ointments. We are told that it is occasionally brought to this country in small fragments mixed with the coarser kinds of gum arabic from the Levant and India. *Unguentum Elemi*, Br. Ph. 1885, was of the strength of about 20 per cent.

Gum, Grass-Tree.—An Australian product, said to be obtained by exudation from different species of *Xanthorrhæa*, especially *X. hastilis*, R. Br. (Fam. Liliacæ.) It is of a resinous character, usually as found in the markets in the state of small fragments or coarse powder, resulting from the breaking up of the larger brittle masses in which it first occurs. It is of a deep reddish-yellow color in mass, but greenish yellow in powder. It does not dissolve in the mouth when chewed, nor adhere to the teeth, but has a slightly astringent and aromatic flavor. It melts with heat, and at a higher temperature takes fire in the air, burning with a smoky flame, and emitting a fragrant odor not unlike that of balsam of Tolu. It yields picric acid largely under the action of nitric acid. The natives and early settlers employed it as a medicine in *diarrhæa*. It is said to be used extensively, instead of shellac, in cabinet work, but to be distinctly inferior. For much interesting information concerning it and other resinous products of the genus *Xanthorrhæa*, see paper by J. H. Maiden, *P. J.*, vol. xxi. 1891. It is obtainable in inexhaustible quantities, as the plants producing it are abundant throughout almost the whole of Australia. (*A. J. P.*, 1866, 465.) Three hundred tons of the resin of *X. hastilis* have been exported in one year, and at one time the price rose to £65 per ton for the best quality, but for ordinary quality it is from £7 to £10. (*A. J. P.*, 1885, 405.) (See article on *Xanthorrhæa Resins*.)

Gum Hogg. *Hog-Gum.* *Kuteeragum.*—Under the name of Gum-Hogg a peculiar gum is much used in marbling paper. A full discussion of it may be found in the 14th edition of the *U. S. D.*, but, as it appears to be only a variety of Bassora gum, and rarely found in commerce, we omit any further account of it.

Gum, Indian. *Gummi Indicum.* *Ghati Gum.* A gummy exudation from the wood of *Anogeissus latifolia*. (Fam. Combretacæ.) The forests of India produce large quantities of gums, a number of which have found their way into commerce and are used to a considerable extent as substitutes for gum arabic.

Of these gums,¹ that yielded by *Prosopis spicijera* occurs in small angular yellowish fragments, or sometimes in large ovoid tears two inches long, of an amber color, frosted externally with cracks. It forms with water a dark-colored tasteless mucilage and resembles in its behavior to reagents the *Mezquite gum*. The gum of *Feronia elephantum* is in small irregular tears varying from reddish-brown to pale yellow and forms a thick, tasteless, colorless mucilage which resembles gum arabic, but is precipitated by neutralized lead acetate and gelatinized by ferric chloride, although unaffected by borax. The most important of the Indian gums is that which has been recognized in the Br. Add., and which in its solubility and relation to reagents closely resembles gum arabic. It has double the power of viscosity of gum arabic and forms with water a colorless mucilage having a faint characteristic odor. It is well suited for pharmaceutical use, and is said to be specially valuable in the making of emulsions. It is insoluble in 90 per cent. alcohol. It occurs "in vermiform or rounded tears of varying size, pale amber or yellowish-white in color, translucent, with a somewhat dull surface and breaking with a bright glassy fracture. The aqueous solution is gelatinized by the addition of alcohol (90 per cent.), solution of borax, or solution of lead subacetate; but it is unaffected by the addition of test-solution of ferric chloride (distinction from Amrad and certain other gums) or of solution of lead acetate. It is not colored blue or brown by a small quantity of solution of iodine (absence of starch or commercial 'dextrin'). On incineration Indian Gum should not yield more than 4 per cent. of ash." Br. Add.

The Br. Add. allows of the substitution of Indian gum in official preparations in place of gum acacia, with the statement that one part of it should be substituted for two of the acacia. The *mucilage of Indian gum* (*Mucilago Gummi Indici*, Br. Add.) is made with two avoirdupois ounces of gum to six fluidounces of distilled water.

Gum Kauri.—This is an amber-like substance, varying from a soft cream-white to an amber color, dug in large quantities from the soil of New Zealand. It is a resinous exudation from *Agathis australis* (Lamb.), Steud. (*Dammara australis*, Lamb.), of the fam. Coniferae, but, as it first exudes and is found on the surface of the ground, it is not esteemed. According to Tschirch and Niederstadt, it contains *kaurinic acid*, $C_{10}H_{16}O_3$, 1.5 per cent.; *a*- and *β*-*kaurolic acids*, $C_{12}H_{20}O_3$, 48 to 50 per cent.; *kaurinolic acid*, $C_{17}H_{34}O_2$, and *kauronolic acid*, $C_{12}H_{24}O_3$, together, 20 to 22 per cent. All these resin acids are soluble in solution of sodium hydroxide. *Baume Calédonien* consists of a solution of kauri gum in an equal weight of 90 per cent. alcohol. It has been used with alleged great success in the treatment of *wounds and ulcers*, of *eczema* and other skin affections, and as a substitute for collodion and the soluble sodium silicate. When applied to a well cleansed and dried wound it leaves a slight deposit of resin as a varnish, which is not affected by friction or contact with water.

¹ There appears to be considerable confusion as to the proper use of the names of Indian gums. *Amrad gum* of the Br. Add. is probably the gum of *Feronia elephantum* (Fam. Rutacæ), but, according to the editors of the *Indian Pharmacopægraphia*, the term *Amrad* is unknown in India and is of African origin applied to dark brown acacia gums. The *ghati gum* of the Indian bazaars is usually a mixed product.

Gum Mango.—This gum, which is obtained from the mango tree, *Mangifera indica*, L., occurs in the Indian bazaars in amber-colored or reddish-yellow lumps, almost transparent, with a brilliant conchoidal fracture, 39.4 per cent. of which is soluble in water. (See *J. P. C.*, 19, 584.)

Gum Mesquite. *Mesquite Gum.* *Gum Mezquite.*—This is the product of *Prosopis juliflora* (Swz.), DC., *P. glandulosa*, Torr., and perhaps other species of the same genus. Mesquite is a small thorny acacia-like tree or shrub belonging to the fam. Leguminosæ, and growing in New Mexico, Texas, and other neighboring regions, where it covers vast extents of country. The fruit is a long, compressed pod, filled with a sweet pulp, which is said to contain 30 per cent. of grape sugar, and to be used by the Indians as food. A gum exudes from the stem and branches. It occurs in irregular, roundish pieces, of various sizes and usually of a dark amber-brown color, though sometimes, especially when gathered from young trees, it is nearly colorless. Procter found it to resemble gum arabic in its solubilities, but to differ essentially in not being precipitated by lead subacetate, and in its strong solution not being coagulated by borax. (*A. J. P.*, xxvii. 224.) Campbell Morfit found in it a very little bassorin (0.206 per cent.), which did not exist in the specimens examined by Procter. (*Am. J. Sci.*, March, 1855, 264.) See also *A. J. P.*, 1855, 542, for a brief description of the gum and its character.

The saccharine pods of *Prosopis odorata*, Torr. and Frem. (*P. pubescens*, Benth.), are largely employed as food by the Indians, and those of all the species form valuable fodder for cattle.

Gum Sassa. *Sassa Gum.*—This name has been applied by Guibourt to a gum, occasionally brought into commerce from the East, and answering to Bruce's description of the product of a tree which he calls *sassa*. According to Guibourt's description, it is in mammillary masses, or in convoluted pieces resembling an ammonite, of a reddish color and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither, like tragacanth, forming a mucilage, nor, like Bassora gum, separating into distinct flocculi. It is rendered blue by iodine.

Gum Sonora. *Sonora Gum.*—According to Krewson the exudation from *Covillea tridentata* (DC.), Vaill. (*Larrea mexicana*, Moric.), contains 17.27 per cent. of resin, and 11.71 per cent. of mucilage and allied substances. (For details see *P. J.*, xvi. 128; also *A. J. P.*, May, 1898.)

Gum Sterculia. *Sterculia Gum.*—A number of trees belonging to the genus *Sterculia* in India, Africa, and Australia yield gums in considerable quantity, most of which resemble in their appearance tragacanth, and some of which have remarkable adhesive properties. These gums have not, however, become important articles of commerce. (See *P. J.*, Nov. 1889; *A. J. P.*, Jan. 1900.)

Gutta-Percha. *Guetah* or *gueutta-pertcha*, Malay (meaning *gueutta*, gum; *pertcha*, rags or scraps). *Gummi plasticum.*—This is a hydrocarbon like India rubber obtained from the juice of certain tropical plants. It is less elastic than India rubber, so that when changed in form by mechanical force it preserves its new shape. At a temperature of boiling water it becomes highly

plastic and capable on cooling of preserving the shapes in which it has been moulded, while India rubber, treated by heat, preserves its elasticity until the temperature becomes excessive, when it changes in its physical and chemical properties. Perhaps the most important difference between the two substances is in their reaction with sulphur, rubber readily vulcanizing, gutta-percha being practically incapable of so doing.

The plants which are capable of yielding gutta-percha are quite numerous, but those yielding the commercial substance inhabit the limited region of South America between the third degree of south and the fifth degree of north latitude, and the limited portion of Asia between longitude 102° and 112°. It is probable that other equatorial or sub-equatorial regions do, however, produce gutta-percha.

Of the true gutta-percha trees, three are or have been especially important, namely, 1. *Paladium Gutta* (Hook. f.), Burck, *Dichopsis Gutta* (Th. Lobb.), B. and H., *Isonandra Gutta* (Serrulaz), *Dichopsis oblongifolium*, Beauvisage (*Paladium oblongifolium*, Burck), *Isonandra oblongifolia*, Teysmann. 2. *Paladium borneense*, Teysmann. 3. *Paladium Treubii* and its variety, *parvifolium*, Burck.

Of these trees the *Paladium Gutta* has been practically exterminated. The *P. oblongifolium* is said to yield the best of all the gutta-perchas, and to be cultivated in Sumatra. Other sapotaceous species of trees yield gutta-percha of inferior quality or in small quantities, and it is stated that *P. pustulatum* is cultivated in Ceylon and *Payena Leerii* is cultivated in its native Sumatra.

Gutta-percha is obtained in considerable quantity in the Philippine Islands, whence it is sent to Singapore. In obtaining gutta-percha, after the tree has been cut down, incisions are made through the bark into the latex, and the milk, after having been collected in gourds, is coagulated by heat, the resulting masses washed by kneading with water, increased in weight by additions of wood, dirt, pebbles, etc., and finally sent into trade worked into masses with a fair exterior.

It has been proven by the researches of Jungfleisch that the leaves of the gutta-percha trees contain, even after drying, nine per cent. of gutta-percha, as extracted by toluene. Hitherto the leaves have been simply lost in the forest. It is further stated that the year's product of leaves of the thirty year old tree will yield as much gutta-percha as does the tree when cut down, and efforts are being made to induce the Malays to collect the leaves instead of destroying the trees. Patents have been taken out for at least four different processes, in which carbon disulphide, toluene, rosin oil, and light petroleum are used as solvents.

In Singapore the gutta-perchas of various sources are mixed, and three commercial articles are sold,—viz. (1) first quality, (2) medium quality, (3) white gutta-percha.

Small quantities of commercial gutta-percha may be freed from impurities and obtained perfectly white by dissolving one part of gutta-percha in twenty of boiling benzene, shaking the solution frequently with calcium sulphate, which upon standing two or three days carries down with it the coloring matter, then decanting the clear liquid, and adding it, in small portions at a time, to alcohol, agitating continually. The deposited gutta-percha is then dried by exposure to the air.

Gutta-percha is of a dull white or whitish color, often with reddish-brown streaks, of a feeble odor, tasteless, at ordinary temperatures hard and almost horny, somewhat flexible in thin pieces, having an unctuous feel under the fingers, and very tenacious. Its sp. gr. is 0.9791. (Soubeiran.) At about 49° C. (120.2° F.) it becomes softer and more flexible, but is still elastic, resisting, and tenacious. At from 66° to 71° C. (150.8° to 159.8° F.) it is soft, very plastic, and capable of being welded and moulded into any form; "plastic above 120° F. (48.8° C.)." Br. It can be softened either by means of hot water or by dry heat. On cooling, it reassumes its former state, and retains any form which may have been given to it. In the softened state it is readily cut with a knife, though with some difficulty when cold. Exposed to a heat of 166° C. (330.8° F.), it loses a portion of water, and on hardening becomes translucent and gray; but it recovers its original characters if immersed in water. Subjected to igneous distillation, it yields volatile products resembling closely the volatile oil obtained from caoutchouc by the same process. Heated in an open vessel, it melts, foams up, and takes fire, burning with a brilliant flame and much smoke. A portion thus melted retains the state of a viscid fluid on cooling. Gutta-percha is a non-conductor of electricity. It is insoluble in water, alcohol, alkaline solutions, and the weak acids. Ether and the volatile oils soften it in the cold, and imperfectly dissolve it with the aid of heat. Oil of turpentine dissolves it perfectly, forming a clear, colorless solution, which yields it unchanged by evaporation. It is also dissolved by carbon disulphide, chloroform, benzene, and petroleum benzin. It has an ultimate composition closely analogous to if not identical with that of caoutchouc. According to Baumhauer, pure gutta-percha, as it issues from the tree, is a hydrocarbon, with the formula ($C_{10}H_{16}$), which he calls *gutta*, and by the oxidation of which, in various degrees, the different bodies constituting gutta-percha are produced. This hydrocarbon can be separated by treating gutta-percha with diluted hydrochloric acid, and boiling the residue with ether, which deposits the gutta on cooling, but the ethereal treatment must be frequently repeated to obtain it quite pure. (*J. Pr. Chem.*, lxxviii. 279.) Arpe considers gutta-percha as a mixture of six different resins, which may have been formed from a hydrocarbon, $C_{10}H_{16}$. (See *Chem. Gaz.*, ix. 471.) Oudemans (*Jahresb.*, 1859, 517) finds two resinous products in gutta-percha: *fluavil*, fusing at 42° C. (107.6° F.), with the formula $C_{20}H_{32}O$, and soluble in cold alcohol, and *albane*, fusing at 140° C. (284° F.), with the formula $C_{10}H_{16}O$, and soluble in chloroform, carbon disulphide, and ether, from which last it crystallizes out on cooling. Payen has shown that three proximate principles exist in the natural gutta-percha,—viz., *gutta* (insoluble in cold alcohol and in boiling alcohol), 78 to 82 per cent.; *fluavile* (insoluble in cold alcohol), 4 to 6 per cent.; *albane* (soluble in boiling alcohol), 14 to 16 per cent. Gutta-percha resists putrefaction strongly; but in certain situations, as when employed to protect underground telegraph wires passing near the roots of the oak, it has been observed to undergo speedy decomposition, in consequence, it is supposed, of the action of fungi. (*P. J.*, xvii. 193.)

Gutta-percha is employed very largely in the arts for various purposes, especially as a protection to electrical wires. In medicine it is used

simply for mechanical purposes, as in the formation of splints and the manufacture of surgical instruments. For details of its use the reader is referred to works on surgery.

Gymnema. *Gymnema silvestris*, R. Br.—This is a woody climber, belonging to the Asclepiadaceæ, which grows in India and also in Africa. The root has for a long time been employed by the natives as a remedy in *snake bite*, and it is affirmed by T. Dyer (*Nature*, 1887) that directly after the eating of one or two leaves it is impossible to taste sugar, though other tastes are not obscured. Thus, pungency alone is detected in gingerbread, and a sweet orange tastes like a lime. The active principle, *gymnemic acid*, was discovered by Hooper, and has been used with considerable success as a remedy for *paragesia* and *hallucinations of taste*. The 1 per cent. aqueous solution is to be applied with a brush to the inside of the mouth, or a hot infusion (15 per cent.) of the crude drug may be used. (See *Th. M.*, Bd. ix.)

Gymnocladus. *Gymnocladus canadensis*, Lam. (*G. dioica* (L.), Koch). *Coffee-tree*, *Kentucky Mahogany*. (Fam. Leguminosæ.)—According to Bartholow, the aqueous extract of the seeds is toxic. (*Am. Drug.*, April, 1886.) Samuel S. Mell (*A. J. P.*, 1887, 230) obtained from them by petroleum benzol about 10 per cent. of fixed oil which is yellowish, saponifiable, and of sp. gr. 0.919. Ether extracted a little wax, fat, and resin. A little tannin and a small quantity of glucoside were also obtained. This latter had a peculiar odor and an acid burning taste. James H. Martin (*A. J. P.*, 1892, 558) obtained a yellow saponifiable oil from the bean and the bark and a glucoside from the pulp.

Hæmoglobin. *Hemoglobin*.—A constituent of venous blood, passing in the arterial blood into *oxyhæmoglobin*. Its molecular formula is extraordinarily complex, the hæmoglobin from the blood of swine having, according to some writers, the formula $C_{699}H_{1005}N_{156}S_3FeO_{179}$, while that from dogs' blood is given as $C_{636}H_{1025}N_{144}S_3FeO_{189}$. Various preparations of *desiccated blood* containing hæmoglobin have been put upon the market. Crystals of hæmoglobin may be obtained from the blood of certain animals (guinea pigs, rats, etc.) with ease by simply adding water to the blood. The hæmoglobin dissolves in the water, the corpuscles separating, and the crystals form in a few minutes. Another method consists in adding to defibrinated blood 6 per cent. of its volume of ether, or a mixture of alcohol and ether; on shaking the mixture, the corpuscles dissolve, and a thick magma of crystals forms sooner or later; these may be purified by washing with 25 per cent. alcohol and by recrystallization. Freezing has been resorted to for the purpose of separating the crystals.

Ferrohemol is a brown, almost tasteless, powder containing 3 per cent. of iron, which is made by the precipitation of blood by a dilute solution of iron and neutralization with soda. *Fer cremol* is a similar substance.

Hemol, *Hemogallol*, are made, as suggested by Kobert, by the action of reducing agents upon the blood coloring matter. (See *E. Merck's Jahresber.*, 1891.) With the hemol, zinc dust is used as the reducing agent; with the hemogallol, pyrogallol is used. The former is a dark brown, the latter a reddish-brown, tasteless powder.

Either of these blood derivatives may be employed instead of the older preparations of iron. There is sufficient clinical evidence to show that they are effective ferruginous tonics which may

be, as is claimed for them, less constipating and less disagreeable to the stomach than are the older preparations of iron; but there is no sufficient reason for believing that they have any real superiority. Dose, five to ten grains (0.32–0.65 Gm.).

A number of hemol preparations have also been recommended by Kobert and prepared by Merck & Co., such as *arsenhemol*, *bromhemol*, *iodohemol*, *iodomercurhemol*, and *copperhemol*.

Hartshorn. Cornu. Lond., Ed. Ph.—The horn of the *Cervus Elaphus*, or stag. (See 16th ed. U. S. D.)

Hedera. *Hedera Helix*, L. *Ivy*. (Fam. Araliaceæ.)—This well-known evergreen creeper is a native of Europe. The fresh leaves have a balsamic odor, especially when rubbed, and a bitterish, harsh, unpleasant taste. They are used for dressing issues, and, in the form of decoction, have been recommended in *sanious ulcers* and *cutaneous eruptions*, particularly *tetter* and the *itch*. The berries, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. Vandamme and Chevallier discovered in ivy seeds a peculiar very bitter alkaline principle, *hederine*. It is obtained by treating the seeds with calcium hydroxide, dissolving the precipitated alkaloid in boiling alcohol, and evaporating the alcoholic solution. (A. J. P., xiii. 172.) Posselt has discovered two acids in the seeds, one of which has their taste in a high degree, and was named by him *hederic acid*, the other he did not obtain quite pure. (See *Chem. Gaz.*, 1849, 93.) The seeds were also found to contain a variety of tannic acid, turning ferric salts dark green, to which Posselt gave the name of *hedera-tannic acid*. (Ann. Ch. Ph., 69, p. 62.) F. A. Hartsen has found in the leaves a crystalline glucoside allied to saponin. (A. J. P., 1875, xlvii. 268.) Davies and Hutchinson confirmed the existence of Posselt's *hederic acid*, and gave it the formula $C_{15}H_{26}O_4$. Kingzett believes that it is not an acid, but a glucoside. J. Vernet (Ber. d. Chem. Ges., xiv. 685) obtained a glucoside, which separated from solution in boiling acetone, in silky needles, melting at 233° C. (451.4° F.), insoluble in water, chloroform, and ligroine, slightly soluble in cold acetone, benzene, and ether, more soluble in hot alcohol and hot alkalies. Its formula he gives as $C_{32}H_{54}O_{11}$, and states that it decomposes on heating with diluted sulphuric acid into a body, $C_{26}H_{44}O_6$, which fuses at from 278°–280° C. (532.4°–536° F.), and a non-fermentable sugar which reduces Fehling's solution. (Y. B. P., 1877, 508.) From the trunks of old ivy plants, growing in the south of Europe and the north of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of *ivy gum*. It is in pieces of various sizes, of a dark yellowish-brown color internally, of a vitreous fracture, pulverizable, yielding a lively orange-yellow powder, of a peculiar not disagreeable odor when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces contain a considerable proportion of bassorin, and other large quantities of ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve *toothache*. The light and porous wood of the ivy is sometimes used for making *issue-peas*.

Hedonal. *Methyl-propyl-carbinol-urethane*, $CO \begin{smallmatrix} \text{NH}_2 \\ \diagup \\ \text{O}(\text{CH}_3.\text{CH}_2.\text{C}_3\text{H}_7) \end{smallmatrix}$. This is a white crystalline powder of weak aromatic odor, fusing at 76° C.

(168.8° F.), sparingly soluble in cold water, somewhat more so in boiling water, soluble in alcohol, ether, and other organic solvents. Decomposed by boiling with alkalies. It forms colorless crystals melting at 76° C. (168.8° F.). The solutions have a powerful menthol-like taste. Hedonal is believed to split up in the system into carbon dioxide, ammonia, and urea. Probably owing to the presence of the urea, it sometimes acts as a diuretic, but more usually it has no other effect than that of an hypnotic. It is claimed by de Moor that its diuretic action is much increased by its administration in solution. According to Dreser, in the dog it acts very feebly upon respiration and blood pressure. As an hypnotic it is mild in its action and but rarely produces disagreeable after effects. In severe cases of *insomnia*, or when the patient is kept awake by pain, it is of little service. No cases of poisoning by it have been reported, and so far its prolonged use has not been followed by disagreeable symptoms. It resembles triional in its action, and when the continuous use of an hypnotic is required, may well be alternated with that drug. The dose is fifteen to forty-five grains (1.0–3.0 Gm.), given preferably in capsules half an hour before the desired effect.

Hedychium. *Hedychium spicatum*, Ham. (Fam. Zingiberaceæ.)—The root of this plant, which is used in India as incense, has been found by J. C. Thresh to contain *ethylmethyl paracoumarate*. (P. J., Nov. 8, 1884.)

Helenium. *Helenium autumnale*, L. *False Sunflower*. *Sneezerwort*. *Sneezerweed*.—An indigenous perennial, bitter, somewhat acrid composite herb. The leaves and flowers snuffed up in the state of powder produce violent sneezing, and have been used as an errhine. F. J. Koch (A. J. P., 1874, 221) found in the plant a bitter principle believed to be a glucoside, malic acid, traces of tannic acid, albumen, volatile oil, etc. *Helenium nudiflorum*, Nutt., has similar properties; *H. tenuifolium*, Nutt., a common roadside weed of Mississippi and Louisiana, is stated by Galloway to produce in animals muscular twitchings, passing into violent convulsions, terminating in death. In four negroes helenium caused spasms with delirium and loss of consciousness. (A. J. P., 1872, 309.)

Helianthemum. *Herbe de Héliantheme de Canada*, Fr. *Canadisches Sonnenröschen*, G. *Helianthemum canadense* (L.), Michx.—*Frostwort*, *frost-weed*, or *rock-rose*, grows in all parts of the Eastern United States, preferring dry sandy soils. William Crutcher (A. J. P., 1888, 390) found in it volatile oil, wax, fatty oil, tannin, and apparently a glucoside crystallizing in white needles. Fred. J. Kruell found in *H. corymbosum*, Michx., tannin in large proportion, resin, glucose, gum, extractive, chlorophyll, and inorganic salts. (A. J. P., 1874, 358.) Frostwort has an astringent, slightly aromatic, and bitterish taste, and appears to possess tonic and astringent properties; it was formerly employed in *scrofulous diseases*. (See U. S. D., 14th ed.) According to D. A. Tyler (Pamphlet, New Haven, 1846), *H. corymbosum* possesses similar properties, and may be indiscriminately employed with *H. canadense* in *scrofula*, *diarrhæa*, and *secondary syphilis*, and locally as a gargle in *scarlatina*, and a wash in *prurigo*. Tyler, however, has known the strong decoction and the extract to produce vomiting. He considers two grains (0.13 Gm.) of the latter a full dose for an adult.

Helianthus. *Helianthus annuus*, L. Common Sunflower. *Hélianthe, Grand Soleil*, Fr. *Sonnenblume*, G.—This very large composite is cultivated in this country, in Europe, and especially in China, chiefly for the sake of the fixed oil yielded by the seed. The oil has a sp. gr. of from 0.924 to 0.926, solidifies at -15° C. (5° F.), is colorless or yellowish, limpid, nearly tasteless and odorless, and dries slowly. It is said to make an excellent salad dressing, and to be one of the best burning oils known. The increase in cultivation is stated to be nearly a thousandfold, 275 pounds of oil being a fair yield per acre. For particulars as to cultivation, see A. J. P., 1875, 460; also N. R., 1876, 165. Ludwig and Kromayer (A. Pharm. (2), 99, 1 and 285) obtained a tannin which they called *helianthitanic acid*, and gave it the formula $C_{14}H_2O_8$. On boiling with moderately diluted hydrochloric acid they obtained a fermentable sugar and a violet coloring matter. E. Diek (In. Dis., Göttingen, 1878) found only small quantities of inulin, large amounts of levulin, and a dextro-rotatory sugar. Chardon has obtained a peculiar oleoresin from sunflowers grown in Algeria. (P. J., 1873, 323.) The stalk, when treated as is flax, yields a long, fine fibre, which is said to be used in China for the adulteration of silk. The sunflower also enjoys the reputation of protecting against marsh miasmata. (See N. Y. M. R., 1868, 353.) Kazatchkoff states (B. G. T., Oct. 1889) that in the Caucasus the inhabitants employ the sunflower in malarial fevers. The leaves are spread upon a bed covered with a cloth, moistened with warm milk, and then the patient is wrapped up in the spread. Perspiration is produced, and the patient is kept in this condition for an hour or two. The same process is repeated every day until the access of the fever has ceased. The Pah Ute Indians are said to use very freely as food the seeds of two indigenous sunflowers, *H. petiolaris*, Nutt., and *H. lenticularis*. (Proc. A. Ph. A., xxvii. 178.)

Helleborus. *Helleborus niger*, L. Black Hellebore. *Hellébore noir*, Fr. *Schwarze Niesswurzel, Weihnachtswurzel, Winterrose, G. Elleboro nero*, It. *Elleboro negro*, Sp.—Hellebore is a native of the mountainous regions of Southern and temperate Europe, and is sometimes cultivated on account of the early opening and beauty of its flowers, whose expansion in midwinter has given to the plant the name of *Christmas rose*. Black hellebore is sometimes called *melampodium*, in honor of Melampus, an ancient shepherd or physician, who is said to have cured the daughters of King Prætus by giving them the milk of goats fed on hellebore.

The formerly official rhizome is knotted, blackish on the outside, white within, and sends off numerous long, simple, depending fibres which are brownish-yellow when fresh, but become dark brown upon drying. (For a history of the use of hellebore by the ancients, see 15th edition, U. S. D.) The roots of various other plants, not belonging to the same genus, are said to be frequently substituted for the black hellebore. They may usually be readily distinguished by comparing them with the genuine root.¹

Though the whole root is found in commerce, the fibres are the portion usually recommended. They are about as thick as a straw, when not broken, from four inches to a foot in length, smooth, brittle, externally black or deep brown, internally white or yellowish-white, with little odor, and a bitterish, nauseous, acrid taste. In their recent state they are extremely acrimonious, producing on the tongue a burning and numbing impression, like that which results from taking hot liquids into the mouth. This acrimony is diminished by drying, and still further impaired by age. Feneulle and Capron obtained from black hellebore a volatile oil, an acrid fixed oil, a resinous substance, wax, a volatile acid, bitter extractive, gum, albumen, potassium gallate, acid calcium gallate, a salt of ammonia, and woody fibre. William Bastick discovered *helleborin*, which he obtained in white, translucent crystals, of a bitter taste with a tingling effect on the tongue, not volatilizable, slightly soluble in water, more so in ether and alcohol, and more readily in these liquids hot than cold. (P. J., xii. 274.) Water and alcohol extract the virtues of the root, which are impaired by long boiling.

Marmé and Husemann obtained from black and green hellebore a glucoside, *helleborein*, $C_{28}H_{44}O_{15}$, by precipitating a solution of an extract of the root with solution of lead subacetate, freeing from lead by hydrogen sulphide, and again precipitating with phospho-molybdic acid; by boiling with acid it separated into glucose and *helleboretin*, $C_{14}H_{20}O_8$, a compound of a fine violet color. The *helleborein* exists both in the root and leaves. It has a taste at once sweet and bitter, is soluble in water and weak alcohol, much less so in ether and absolute alcohol, and is crystallizable in rhomboidal prisms. It is precipitable by tannic acid and mercurous acetate (J. P. C., 4e sér., ii. 258). Husemann and Marmé (Ann. Chem., 135, 61) also examined more thoroughly the *helleborin* of Bastick. They ascribe to it the formula $C_{36}H_{42}O_8$, and find that when boiled with diluted sulphuric acid, or, better, zinc chloride, it is converted into sugar and *helleboresin*, $C_{30}H_{36}O_4$. They obtain this glucoside by treating with hot water the green fatty matter which is dissolved out of the root by boiling alcohol. Though both the principles referred to by the German chemists mentioned are poisonous, the products of their decomposition are said to be harmless. Neither of them is volatile.

Helleborein is strongly irritant to the mucous membranes, causing, when applied to the conjunctiva, redness, swelling, and increased secretion, with indirect enlargement of the pupil, and when applied to the nasal membrane, sneezing, though less than veratrine. Small doses produce little effect on the stomach; but, repeated and accumulated, they cause anorexia, nausea even to vomiting, pain, increased secretion, and inflammation both of the stomach and bowels. It is claimed for helleborein that it acts upon the heart in a manner similar

shaped or almost square wood-bundles; older roots exhibit a wood with from five to seven-pointed rays. In both rhizome and root of *H. fatidus*, L., the wood is more strongly developed and radiate in appearance; it contains abundance of wood-fibres and encloses little or no pith. The rhizome of *Actæa spicata*, L., is flattened and bears cushion-like protuberances, due to the remains of the aerial stems. The wood-bundles are thickened at either extremity and rounded by wood-fibres, so that in transverse section the wood-ring has a scalariform appearance. The root exhibits a regular three to five-rayed wood, the rays being broader toward the outside. (S. W. P., xl. 410.)

¹The rhizomes of various plants which are sometimes substituted for true hellebore have been examined by Tschirch and Neuber, who state their results as follows: The rhizome of *H. niger* exhibits a small pith and comparatively large acutely wedge-shaped, radially-elongated wood-bundles. The root is often flattened and possesses a stellate wood with blunt points. The rhizome of *H. viridis*, L., has a large pith and tangentially extended, bluntly wedge-

to digitalis, in small repeated doses slowing the pulse and increasing the force, in toxic doses increasing the rapidity of the pulse, and in most cases causing a sudden cardiac arrest in systole. The blood pressure in the earlier stages of the poisoning is always increased. Respiration continues after the arrest of the heart. It is affirmed also to increase secretion, especially of the saliva and the urine, and probably to have an action upon the uterus. In very large doses it acts upon the nervous system so as to produce partial paralysis with tremors, which if the dose has been sufficiently large are replaced by violent convulsions. The pupil is variously affected; usually it is dilated before death. There are no characteristic post mortem lesions. As yet the glucoside has not been found in the secretions, and it may be destroyed in the system. The *helleborin* of Marmé and Husemann is a more active poison, though less irritant to the mucous membrane. It acts on the tongue like aconite. Its influence appears to be directed especially to the nervous system. In the lower animals it causes quickened breathing, restlessness, tension and trembling of the muscles, uncertainty of movement; then retardation of the breathing and pulse, irritability of the peripheral nerves, dilatation of the pupil, loss of hearing, and finally almost complete anesthesia, with cerebral and spinal congestion, even to apoplexy.

Black hellebore is a drastic hydragogue cathartic, formerly supposed to be possessed of emmenagogue powers. In overdoses it produces inflammation of the gastric and intestinal mucous membrane, with violent vomiting, hypercatharsis, vertigo, cramp, and convulsions, which sometimes end in death. The fresh root applied to the skin produces inflammation and even vesication. The medicine was very highly esteemed by the ancients in *mania*, *melancholy*, *amenorrhœa*, *dropsy*, and *epilepsy*. *Bacher's pills*, celebrated for the cure of *dropsy*, consisted chiefly of black hellebore. S. B. Botkin and N. Ischistowitsch (*Cb. M. W.*, July 9, 1887), as the result of experiments made with the extract of the root of a green hellebore, conclude that in moderate doses it lessens the rapidity and increases the force of the cardiac contractions, producing a rise in the arterial pressure, the slowing of the beat being the result, at least in part, of stimulation of the inhibitory nerves, since it is prevented by severing of the vagi or by injections of atropine. The cause of the rise of the arterial pressure is believed by the experimenters to be in part due to increased work of the heart, and in part to contraction of the capillaries by an action of the remedy directly upon their coats. Usually the pulse has been increased in force and diminished in frequency and the secretion of urine notably augmented. The results obtained by Botkin have been largely confirmed by Christovich. (*D. M. Ztg.*, Jan. 1888.) Ischistowitsch has seen fifteen drops of a solution of 1 to 100 of the aqueous extract every two hours produce in six cases of cardiac diseases a diminution in the frequency and an augmentation of the force of the cardiac pulsations, an increase in the quantity of urine, and a prompt disappearance of the symptoms of non-compensation. Venturini and Gasparini (*B. G. T.*, June, 1888) state that helleborein is a local anæsthetic, which, in affections of the eye, is preferable to cocaine, because of the great permanency of the anæsthesia, and because neither the pupil nor the intraocular pressure is affected. They use from three to four drops of

the solution, each drop of it representing 1-164th grain (0.0004 Gm.). Hypodermically injected, helleborein is stated also to act as a local anæsthetic, but its powerful influence upon the heart forbids this method of use. The dose of the powdered root is from ten to twenty grains (0.65-1.3 Gm.) as a drastic purge, two or three grains (0.13-0.2 Gm.) as an alterative.

Dose, of the decoction (two drachms to a pint), a fluidounce (30 Cc.) every four hours till it operates.

Helmitol. *Citramine*.—This substance is a white acidulous, odorless powder, soluble in water, but almost insoluble in alcohol, and is said to be a compound of *anhydromethylene-citric acid* and *hexamethylene-tetramine*, 2 Gm. representing 0.85 Gm. of the latter constituent. Theoretically, hexamethylene-tetramine should undergo decomposition in the human system with the formation and subsequent elimination of formaldehyde, and S. Goldschmidt (*Th. M.*, Jan. 1903) states that after the administration of helmitol the formaldehyde is present in the urine when freshly voided. Helmitol has been highly recommended by P. Rosenthal (*Ther. Geg.*, Dec. 1902) in chronic *gonorrhœa* and other infective diseases of the genito-urinary tract. Its value has been confirmed by S. Goldschmidt. It may be given in doses of fifteen to twenty-three grains (1.0-1.5 Gm.) up to forty-five to sixty grains (3-3.9 Gm.) a day.

Helonias. *Chamæirium luteum* (L.), A. Gray (*C. carolinianum*, Willd., *Helonias dioica*, Pursh). *False Unicorn Root*. *Starwort*. (See 18th ed. U. S. D.)

Heracleum. *Heracleum lanatum*, Michaux. *Masterwort*. *Cow-parsnip*.—This is one of our largest indigenous umbelliferous plants. The root, which is the part used, bears some resemblance to that of common parsley. It has a strong disagreeable odor and a very acrid taste. Both the leaves and root excite redness and inflammation when applied to the skin. Bigelow considers the plant poisonous. It appears to be somewhat stimulant and carminative, and has been used in *epilepsy*. (See 16th ed. U. S. D.)

Hermodactyls. *Hermodactyli*.—Under this name are sold in European commerce the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is thought to be a *Colchicum*, and *C. variegatum*, L., a native of the south of Europe and the Levant, is particularly indicated by Fée, Geiger, and others, while by authors no less eminent the roots are confidently referred to *Iris tuberosa*, L. They certainly bear a considerable resemblance to the corm of *Colchicum autumnale*, L., being heart-shaped, channelled on one side, convex on the other, and from half an inch to an inch in length by nearly as much in breadth. As found in commerce, they are destitute of the outer coat, are of a dirty yellowish or brownish color externally, white and amylaceous within, inodorous and nearly tasteless, though sometimes slightly acrid. They are often worm eaten. Their chief constituent is starch, and they contain no veratrine or colchicine. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of *Colchicum*. They are in fact almost without action upon the system. It is doubted whether they are the *hermodactyli* of the ancients, which acted like colchicum and were useful

in gout and rheumatism. Pereira describes a bitter variety of hermodactyls, which was brought from India by Royle. The bulbs are smaller and darker than the others, and have externally a striped or reticulated appearance.

Hermophenyl. *Mercurio-sodic phenol-disulphonate*.—This substance, which contains 40 per cent. of metallic mercury, occurs as a white amorphous powder, freely dissolving in cold water (up to 22 per cent.). According to Lumiere and Chevroliet (*B. M.*, 1901, 690) it possesses very feeble toxic properties, while it is actively bactericidal. Its hypodermic injections are said to cause but little pain. Reynes recommends in *syphilis* the intramuscular injection of a solution of 0.05 Gm. (4.5th gr.) of hermophenyl per 10 Cc. (160 minims) of water, of which he injects 4 Cc. (64 minims) at intervals of two or three days,—i.e., an equivalent of 0.02 Gm. ($\frac{1}{2}$ gr.) hermophenyl or 8 Mgm. ($\frac{1}{2}$ gr.) of metallic mercury. Bernard claims that it may be made into a 1 per cent. soap without decomposition, affording an excellent preparation for rendering the hands aseptic. The 2 per cent. aqueous solution may be used for surgical purposes.

Herniaria. *Herniaria glabra*, L. (Fam. Illecebraceæ.)—Goblez has obtained from this plant a crystalline principle, *herniarine* (*J. P. C.*, 4e sér., xx, 270), which proved to be *methyl-umbelliferone*, $C_{10}H_8O_3$. Schneegans has also discovered an alkaloid, *paronychine*. (*A. J. P.*, 1890, 488.) This plant is recommended by Zeissl in *catarrh of the bladder*.

Heroine Hydrochloride.—The hydrochloride of the diacetic ester of morphine ($CH_3COO)_2C_{17}H_{17}.ON.HCl$, a white odorless bitter powder, melting at 230° C. (446° F.). It is quite soluble in water with neutral reaction. The free base *heroine* is a white crystalline powder melting at 171°–172° C. and possessing an alkaline reaction. It is practically insoluble in water, difficultly soluble in cold alcohol, more readily in hot alcohol, easily soluble in chloroform and benzene.

Heroine hydrochloride is thrown out of solution by the action of caustic alkalies, ammonia, and alkaline carbonates. Heating with mineral acids causes the splitting off of acetic acid, this reaction distinguishing it from codeine. Heroine hydrochloride does not possess the analgesic properties of morphine to any extent. It is, however, an extremely useful cough sedative in *bronchitis* and similar conditions. In *phthisis* especial virtue is claimed for it,—that it diminishes the sweating as well as the cough. *Dose*, one-sixteenth to one-eighth grain (0.004 to 0.008 Gm.).

Heteromeles. *Heteromeles arbutifolia* (Poir.), Roem. (*Photinia arbutifolia*, Lindl.) (Fam. Pomaceæ.)—D. D. Lustig has found in this Californian plant (*toyon* of the Indians) tannic, gallic, and hydrocyanic acids. (*A. J. P.*, April, 1882.)

Hetocresol. *Metacresol Cinnamate* ($C_6H_5CH=CH.COOC_6H_4CH_3$).—Forms crystals melting at 65° C. (149° F.), insoluble in water, but soluble in alcohol, ether, benzene, chloroform, and glacial acetic acid. It is claimed that this substance is especially valuable as a local remedy in external *tuberculosis*. In *tuberculosis of the bladder* Landerer uses, after cocaineization, 1.4 per cent. solutions containing 0.7 per cent. of common salt. Fistulous tracts he injected with hetocresol, 1 part; iodoform, 2 parts; water, 1 to 8 parts. In *scrophuloderma*, after scraping, hetocresol has been found to be very useful.

Hetralin. *Dioxybenzenehexamethylenetetramine*. Soluble in four parts of hot water and in fourteen of cold water. Contains 60 per cent. of *hexamethylene-tetramine*. It is used in the *dose* of twenty-three to thirty grains (1.5–2.0 Gm.) a day, in divided doses. Highly commended in specific inflammation of the genital organs. (Lederman.)

Hetol.—Sodium cinnamate, $C_6H_5.CH=CH.COONa$ is a white powder soluble in water.

Heuchera. *Heuchera americana*, L. (*H. cor-tusa*, Michaux. *H. viscida*, Pursh.) *Racine d'Heuchere d'Amérique*, Fr. *Amerikanische Sanikelwurzel*, G.—The alum-root or American sanicle is a perennial, herbaceous plant, belonging to the Saxifragaceæ, which grows in shady, rocky situations from New England to Carolina. The root, which was formerly official, is horizontal, somewhat compressed, knotty, irregular, yellowish, and of a strongly styptic taste. Alum-root is powerfully astringent, and may be employed in similar cases with other medicines belonging to the same class. H. K. Bowman (1869) obtained from it 18 to 20 per cent. of tannin. It has hitherto, however, been little used. J. Peacock (*A. J. P.*, 1891, 174) found a percentage of tannin ranging from 9.33 to 19.66 reckoned on the dry drug, according to the season of the year when collected; also a percentage of starch, calculated the same way, ranging from 5.17 to 16.32. Frederick Stearns (*Proc. A. Ph. A.*, 1858, 263) speaks of two other indigenous species, *H. villosa*, Michx. (*H. caulescens*, Pursh), and *H. pubescens*, Pursh, as having similar properties; and F. W. Anderson reports (*Botan. Gaz.*, 1887, 65) that the roots of *H. hispida*, Pursh, *H. cylindrica*, Douglas, and *H. parvifolia*, Nuttall, are much used by hunters of Montana and others as astringents, particularly in *diarrhœa* caused by the drinking of alkali water.

Hibiscus. *Hibiscus Abelmoschus*, L. (*Abelmoschus moschatus*, Medic.) (Fam. Malvaceæ.) An evergreen shrub, growing in Egypt, and in the East and West Indies, and yielding the seeds known under the names of *semen Abelmoschi vel alcea Egyptiacæ*, and *grana moschata*. These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown color, of an odor like that of musk, and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic, but are now used only in perfumery. The Arabs flavor their coffee with them. They are said to be employed in the adulteration of musk. Another species, *Hibiscus esculentus*, L., or *Abelmoschus esculentus*, Moench, is cultivated under the name of *okra*, *bendee*, or *gombo* in various parts of the world, for the sake of its fruit, which abounds in mucilage (*gombine*), and is used for thickening soup. The leaves are sometimes employed for preparing emollient poultices. The roots, which are a foot or two long, are said also to abound in mucilage free from any unpleasant odor. Their powder is perfectly white, and superior to the marshmallow. The plant is largely cultivated near Constantinople, where it is much used as a demulcent. (*A. J. P.*, 1860, 224.) The bark is also used in making paper and cordage.

Hieracium. *Hieracium venosum*, L. (Fam. Compositæ.) *Rattlesnake Weed*. *Epervière*, Fr. *Habichtskraut*, G.—The plant is common, growing in dry places and open woods, in most of the eastern and northern parts of the United States and in Canada. The leaves and root are thought to

possess medicinal virtues, and, being deemed astringent, have been used in *hemorrhagic diseases*. The juice is supposed by some to have the power of removing *warts*. *Dose* of infusion (two ounces to the pint), a wineglassful (60 Cc.).

Hippuric Acid. ($C_9H_9NO_3$). *Benzoylglycocol*, $CH_2 \begin{cases} NH.C_6H_5O \\ COOH \end{cases}$. This occurs in considerable amount in the urine of herbivorous animals, sometimes in that of man. Benzoic and cinnamic acids, toluol, and other aromatic substances, when taken internally, are eliminated as hippuric acid. It crystallizes in rhombic prisms, melting at $187^\circ C.$ ($368.6^\circ F.$), and at about $240^\circ C.$ ($464^\circ F.$) decomposes into benzoic acid, benzonitrile, and prussic acid. Boiling acids or alkalis decompose it into benzoic acid and glycocol. According to the experiments of Meissner and Shepard, hippuric acid injected into the blood of animals acts as a very decided poison, but the hippurates have been suggested by Garrod as a remedy in the *uric acid diathesis*. He affirms that if outside of the body the sodium hippurate be added to blood serum that shows the presence of a urate, the latter is soon removed. *Sodium hippurate* may be combined with lithium or potassium salts; the *dose* is ten grains (0.65 Gm.) three times a day.

Histogenol.—Monneyrat (*Prog. M.*, April, 1902), finding that *sodium methylarsenate* ($OAsCH_3O_2Na_2$) was not poisonous, has combined it with nucleinic acid to form this preparation, which he claims to be of great value in the treatment of *tuberculosis*.

Hoang-Nan.—This is the bark of *Strychnos malaccensis*, Benth. (Fam. Loganiaceæ), a climbing plant, which grows in Malacca and surrounding countries. Brucine and strychnine are stated to have been found in it (*Newer Mat. Med.*), brucine being the more abundant of the two. It has been found to produce in animals general tetanic spasms similar to those caused by strychnine. It probably has the same range of medicinal application as has *nux vomica*, although special virtues have been claimed for it in the treatment of *chronic skin diseases*. *Dose* of powdered bark, three grains (0.2 Gm.).

Holigarna. *Holigarna longifolia*, Roxb. (Fam. Anacardiaceæ).—According to David Hooper (*P. J.*, xxv, 1895), the black juice of this tree, which is used in India as the basis of a varnish, is actively vesicant, and contains a body closely allied to, if not identical with, cardol.

Holocaine, *p*-Diethoxyethenyl diphenylamine, $C_6H_4 \begin{cases} OC_2H_5 \\ NH.C(CH_3)=N.C_6H_4(OC_2H_5) \end{cases}$, formed by the condensation of molecular amounts of phenacetin and paraphenetidine. The free base crystallizes well, is insoluble in water, and melts at $121^\circ C.$ ($249.8^\circ F.$).

Holocaine Hydrochloride forms colorless, lustrous, odorless crystals, melting at $189^\circ C.$ ($372.2^\circ F.$). It is soluble in 45 parts of water and readily in alcohol, with neutral reaction. The salt commonly used of the base is the hydrochloride, which readily dissolves in boiling water, leaving on cooling a saturated solution containing about $2\frac{1}{2}$ per cent. of the hydrochloride. This solution is slightly bitter, neutral in reaction, and keeps many months without change. In boiling, a porcelain vessel should always be used, as the solution at $212^\circ C.$ attacks glass.

It has been brought forward as a local anæsthetic in the treatment of diseases of the eye. The

anæsthesia, which is said to develop in from fifteen seconds to a minute after the instillation of the solution, lasts from ten to fifteen minutes. The amount of burning produced is about the same as with cocaine. The advantages which are claimed for it over the latter alkaloid are that it does not change the pupil, the accommodation, or the intra-ocular pressure, and is antiseptic. It does not contract the blood vessels. The objections to it are that the instillation has to be renewed in from ten to fifteen minutes, and that it is about five times as toxic as is cocaine, so that it cannot be used hypodermically. According to the experiments of Heinz and Schlosser (*Klin. Monat. f. Augen.*, xxxv, 1897), the $\frac{1}{2}$ of 1 per cent. solution affects bacteria, while the 1 per cent. solution is a powerful germicide, rapidly killing the lower organisms, including infusoria. Even in small doses it causes in frogs and in mammals violent convulsions which appear to be of cerebral origin, since after division of the spinal cord in the mouse the convulsions were confined to the anterior portion of the body. Holocaine is an active muscle poison, the 1 per cent. solution rapidly killing voluntary and cardiac muscles in the frog, and it exerts also a curare-like influence upon the motor nerves. According to Winselmann, its 1 per cent. solution exceeds in anæsthetic power the 3 per cent. solution of cocaine.

Honthin.—This is a grayish-brown odorless and tasteless powder, insoluble in water but yielding a light-brown solution in alcohol and in aqueous alkali, in which it is partly soluble. It is said to be chemically a *keratinized albumin tannate*. It is given in *doses* of from ten to twenty grains (0.65–1.3 Gm.) three to five times daily, as an astringent, in all forms of *diarrhœa*, without great irritation.

Hoochinoo.—This is an alcoholic drink which is clandestinely distilled by the Alaskan Indians, and has been supposed, on account of the frenzy which it produces in them, to contain some poisonous substance other than alcohol. John Marshall found it, however, to be simply an alcoholic liquor of about the strength of sherry.

Hordeum.—Several species of the graminaceous genus *Hordeum* are cultivated in different parts of the world. The most common are *H. vulgare*, L., and *H. distichon*, L., both of which have been introduced into the United States. The original country of the cultivated barley is unknown. The plant has been found growing wild in Sicily and in various parts of the interior of Asia. *H. vulgare* is said by Pursh to grow in some parts of the United States, apparently in a wild state. The fruits or grains are used in various forms.

1.—In their natural state they are oval, oblong, pointed at one end, obtuse at the other, marked with a longitudinal furrow, of a yellowish color externally, white within, having a faint odor when in mass, and a mild sweetish taste. Careful analyses of barley have been made, which agree in the main, though differing in some details, especially as to whether any sugar exists in the barley before malting.

Pillitz found (*Zeit. An. Chem.*, 1872) in the dry barley 14.3 per cent. of insoluble albuminoids, 2.1 per cent. of soluble albuminoids, 62.6 per cent. of starch, 1.9 per cent. of dextrin, 2.7 per cent. of sugar, 1.7 per cent. of extractive material, 3.1 per cent. of fat, 1.4 per cent. of soluble ash, 1.2 per cent. of insoluble ash, and 8.9 per cent. of lignin. The presence of sugar seems to have been shown by Kühnemann (*Ber. d. Chem. Ges.*, 1875

and 1876), who found a crystallized dextrogyrate sugar which did not reduce alkaline copper solution, and an amorphous lævogyrate mucilaginous substance called *sinistrin*. According to Kühnemann, barley does not contain dextrin.

Clifford Richardson (*Bulletin No. 9, Department of Agriculture*, 1886) gives the following as the average composition of American barley: water, 6.47 per cent.; ash, 2.87; oil, 2.67; sugar, etc., 7.02; dextrin and soluble starch, 3.55; starch, 62.09; albuminoids soluble in 80 per cent. alcohol, 3.66; albuminoids insoluble in 80 per cent. alcohol, 7.80; fibre, 3.81; total, 100.00. He finds, moreover, that on an average the grain makes up 84.78 per cent. and the hull 15.22 per cent. of the barley.

2.—*Malt* consists of the seeds made to germinate by warmth and moisture, and then baked so as to deprive them of vitality. It is in the form of malt that barley is so largely consumed in the manufacture of malt liquors. (See *Maltum*.) *Diastase* was first discovered by Payen and Persoz in the seeds of barley, oats, and wheat, and in the potato. It is found, however, only after germination, in which process the production of it appears to be the first step. Germinated barley seldom contains it in larger proportion than two parts in a thousand. It is obtained by bruising freshly germinated barley, adding about half its weight of water, expressing strongly, treating the viscid liquid thus obtained with sufficient alcohol to destroy its viscosity, then separating the coagulated albumen, and adding a fresh portion of alcohol, which precipitates the diastase in an impure state. To render it pure, it must be redissolved as often as three times in water, and precipitated by alcohol. It is solid, white, tasteless, soluble in water and weak alcohol, but insoluble in the latter fluid when concentrated. Though without action upon gum and sugar, it has the property, when mixed, in the proportion of only 1 part to 2000, with starch suspended in water, and maintained at a temperature of about 71.1° C. (160° F.), of converting that principle into dextrin and maltose.

This latter is a variety of sugar and was first recognized by Dubrunfaut, but has been more thoroughly studied by O'Sullivan and by Schulze. Its formula is $C_{12}H_{22}O_{11} + H_2O$; the molecule of water of crystallization it loses at from 100° to 110° C. (212°–230° F.) (or, as Richter proposes, it may have the formula $C_{12}H_{34}O_{17}$). O'Sullivan (*J. Chem. S.*, 10, 597) explains the action of diastase upon starch by the following reactions:

At 63° C. (145.4° F.):

At from 64°–70° C. (147.2°–158° F.):

At 70° C. (158° F.):

The crystals of maltose, $C_{12}H_{22}O_{11} + H_2O$, are soluble in water and alcohol, they reduce Fehling's solution, and, according to O'Sullivan, are equal to from 63.9–65.5 per cent. of dextrose, but, according to Schulze, they are equal to from 66–67 per cent. of dextrose, and show a specific rotatory power of $[\alpha]_D = 150^\circ$ to the right. The whole of the starch undergoes this change, except the teguments of the granules, amounting to about 4 parts in 1000. The change which barley undergoes during germination, and in malting, is of a similar character. The purity of diastase may be tested by mixing 0.05 part of it with 200 parts of paste containing 10 parts of starch; after standing, the

resulting liquid should filter rapidly, and decolorize five times its volume of Fehling's solution. The diastases are now recognized as a class of enzymes and known specially as amylolytic or saccharifying ferments, as their special function is the transforming of starch into sugars. We include in this class *plant diastase* and *animal diastases* such as the *amylpsin* of the pancreas and the *ptyalin* of the saliva.

Besides the diastase a second soluble ferment is formed during the malting process, the so-called *peptase*, which in the mashing process changes the proteids of the malt into peptones and parapeptones, which give nutritive value to the beer obtained from malt. For a fuller account of the composition and functions of malt, see Sadtler's *Industrial Organic Chemistry*, 179 *et seq.*

3.—*Hulled barley* is merely the grain deprived of its husk, which, according to Einhoff, amounts to 18.75 parts in the hundred.

4.—*Barley meal* is formed by grinding the seeds, previously deprived of their husk. It has a grayish-white color, and contains, according to Fourcroy and Vauquelin, an oleaginous substance, sugar, starch, nitrogenous matter, acetic acid, calcium and magnesium phosphates, silica, and iron. It may be made into a coarse, heavy, hard bread, which in some countries is much used for food.

5.—*Pearl barley* (*Hordeum decortiatum*, Br. 1885) is the seed deprived of all its investments and afterwards rounded and polished in a mill. It is in small round or oval grains, having the remains of the longitudinal furrow of the seeds, and of a pearly whiteness. It is wholly destitute of hordein, and abounds in starch, with some gluten, sugar, and gum. This is the proper form of barley for medicinal use.

Barley is one of the mildest and least irritating of farinaceous substances, and forms, by decoction with water, a mucilaginous drink much employed from the time of Hippocrates to the present. Pearl barley is the form usually preferred for the preparation of the decoction, made by pouring four pints of boiling water on two troyounces of pearl barley and boiling away to two pints, and straining. Malt affords a liquor more demulcent and nutritious, and the decoction of malt may be prepared by boiling from two to four ounces in a quart of water, and straining. When hops are added, the decoction takes the name of *wort*, and acquires tonic properties, which render it useful in debility.

Houttuynia. *Houttuynia californica*, B. and H. (*Anemopsis californica*, Hook. et Arn.).

Yerba Mansa.—The root of this piperaceous Californian plant is employed by the natives in *chronic malaria*, and also in *diarrhœa* and *dysentery*, and has been used with asserted good results in *gonorrhœa* and *rheumatism*. For elaborate histological study, see D. C., May, 1897. *Dose* of the fluidextract, from fifteen to sixty minims (0.9–3.75 Cc.).

Huamanripa.—This is a Chilean drug, the plant growing on the slope of the Cordilleras at considerable heights. Lapater found it to be stimulating, emetic, sialagogue, and diaphoretic. (*West. Drug.*, 1886, 410.)

Hura. *Hura crepitans*, L. (*H. brasiliensis*, Willd.) *Assacou*. *Sablier*, Fr. *Sandbüchsenbaum*, G.—This is a Brazilian tree belonging to the family of Euphorbiaceæ. It is characterized by the tendency of its fruit when ripe to break with violence into several pieces, and thus scatter the seeds. It is an acrid emeto-cathartic; in large

doses acting as a violent poison. The fresh juice, the seeds, and a decoction of the bark all have these properties; an oil expressed from the seeds is actively purgative. The juice of *Hura crepitans*, which, according to J. J. Surie (*Nederl. Tijdsch. voor Pharm.*, 1900, 107), contains a volatile, colorless liquid, *hurin*, closely allied to cardol and is stated by Martius to be used to intoxicate fish, it has been employed to a considerable extent with alleged favorable results in the treatment of the elephantiasis, or leprosy, of Brazil. The juice is extremely acrid, producing on the skin, when applied to it, an erysipelatous redness and a pustular eruption; the natives are said to employ it in the preparation of a poison. A grain (0.065 Gm.) of the juice made into a pill, or twenty grains (1.3 Gm.) of the bark infused in a pint of water, is given every day, and gradually increased as the stomach and bowels will bear it. Every week an emetic preparation is administered, made by boiling half an ounce (15.5 Gm.) of the bark in a pint of water to half a pint, to which twelve drops of the juice are added. Every second or third day the patient takes a bath in a saturated infusion of the bark. (*J. P. C.*, xiv. 424.)

Hydracetic. *Pyrodine*.—The hydracetic of commerce is stated to be a varying compound, whose active principle is *acetylphenylhydrazin* ($C_6H_5.NH-NH.C_2H_5O$). It is soluble in alcohol and in water in proportion of 1 to 50. According to Guttman (*Ph. Centralh.*, May 16, 1889, 311), hydracetic is a powerful antipyretic and antirheumatic remedy. It occurs as a white, odorless, almost tasteless crystalline powder, melting at from 128° – 129° C. (262.4° – 264.2° F.). It is stated that it cannot be continuously used without danger. Externally, hydracetic is used in place of chrysarobin in psoriasis and similar disorders, in an ointment of from 5 to 15 per cent. *Dose*, three-quarters of a grain (0.048 Gm.) two or three times a day.

Hydrangea. *Hydrangea arborescens*, L. *Common Hydrangea*. *Seven Barks*. (Fam. Saxifragaceae.)—The root of our indigenous Hydrangea, which is the only part used, consists of a caudex, from which proceed numerous radicles, from the thickness of a quill to that of a finger or more. For use it should be cut into transverse pieces when fresh, and then dried. The taste is aromatic, pungent, and not unpleasant. Bondurant (*A. J. P.*, 1887, 122) has isolated a characteristic glucoside, *hydrangin*, crystallizing in stellate clusters, melting at 235° C. (455° F.), and subliming without decomposition. It is decomposed by dilute acids into a resin-like body and glucose. Its aqueous solution fluoresces strongly on addition of an alkali, resembling æsculin, but distinctly different in several particulars. Bondurant also obtained a fixed oil and a volatile oil, the latter containing sulphur. Two resins seemed also to be present, together with saponin and sugar. He found no tannin, however. Its decoction is said to have been used with great advantage among the Cherokee Indians, and subsequently by settlers, in *calculus diseases*. (See *N. J. Med. Rep.*, 1850, 1854, and 1885.) In overdoses it occasions vertigo, oppression of the chest, etc.

Hydrargyrol. ($C_6H_4.OH.SO_3$)₂Hg. *Mercury Paraphenolsulphonate*.—This salt occurs in brownish-red scales, having a gingerbread-like odor, neutral reaction, and sp. gr. 1.85. It dissolves in water and glycerin, with a ruby-red color. It is said to contain over 53 per cent. of quicksilver, and not to precipitate albumin. It has been pro-

posed by Gautrelet as a substitute for corrosive sublimate in antiseptic surgery. A solution of 4 to 1000 is not irritant to the mucous membrane or skin, but very active as an antiseptic, sterilizing bouillons at once. When taken in large doses it is toxic, thirty and a half grammes of it having caused death; but, according to its introducer, as a poison it is seventy-five times less active than is corrosive sublimate.

Hydrocotyle. *Hydrocotyle asiatica*, L. *Centella asiatica* (L.). Urban. *H. repanda*, Pers. *Thick-leaved Pennywort*. *Indian Pennywort*. *Bevilacqua*, Fr. *Wassernabel*, G.—This is a small umbelliferous plant growing in Southern Africa and in India, where it has long been used as an alternative; it is apparently indigenous also in the Southern United States. Jules Lépine discovered in it a peculiar oleaginous substance, *vellarine*, having a strong odor recalling that of the plant, and a bitter, pungent, and persistent taste. (*J. P. C.*, 1885, 49.) It is said to be diuretic, and has been given in fever and bowel complaints; also in syphilitic and scrofulous affections. (*P. J.*, 1860.)

C. Daruty de Grandpré (*Nouv. Rem.*, April 8, 1888) finds that in small doses it is an energetic stimulant, and that in large doses it is narcotic, producing stupor, headache, and in some persons vertigo with a tendency to coma.

Hydrofluoric Acid. *Acidum Hydrofluoricum*. (See *Fluorides*.)

Hydrogen Sulphide. *Hydrosulphuric Acid*. *Sulphuretted Hydrogen*. H_2S .—A colorless gas of unpleasant odor, soluble in water, to which it imparts an acid reaction. 3.23 volumes of gas are absorbed by one volume of water at 15° C. (59° F.). Also soluble in alcohol. Has been liquefied at ordinary temperatures under a pressure of 17 atmospheres, or at ordinary pressures by a cold of -74° C. (-101.2° F.), and at -85° C. (-121° F.) becomes an ice-like solid.

The symptoms of poisoning by hydrogen sulphide vary with the amount taken. Its inhalation in a concentrated form is followed by giddiness, nausea, excessive weakness, and rapid or immediate loss of consciousness. The very diluted gas produces nausea, pain in the head, and great general weakness; followed, if sufficient be taken, by coma, or stupor with delirium, and in some cases by general convulsions. The blood becomes of a brownish-black color, and after death remains fluid. The general appearances at the autopsy are not to be distinguished from those produced by the absorption of carbon dioxide, but the diagnosis is readily made by the odor which pervades the whole corpse.

Bruère (*J. A. P.*, Oct. 1891) finds that bright red diluted blood under the influence of the sulphide becomes of an olive-green color, and that out of the oxyhemoglobin a new compound is formed, *sulphmethemoglobin* or *sulphamoglobin*, probably by a union of hydrogen sulphide with hæmatin. It has been shown by Paul Binet (*Rev. Méd. de la Suisse Rom.*, xvi. 1896) that this sulpho-methemoglobin is produced in the blood during life, especially when the gas is in very large amount. It is worthy of remark that Bruère found hydrogen selenide and hydrogen telluride to act the same as the hydrogen sulphide.

In 1886 Bergeon proposing to the French Academy a method of treating tuberculosis by injecting hydrogen sulphide, diluted with pure carbon dioxide, into the large intestine, the method being founded upon the supposed power of hydro-

gen sulphide to destroy the tubercule bacillus. The method of Bergeon had an extraordinary run, and then fell rapidly into desuetude, but there can be no doubt that the hydrogen sulphide has a distinct influence upon mucous membrane. It is a useful remedy in *pulmonary catarrh*, chronic or acute, as well as in *chronic rheumatism* and in *gout*. It is for this reason that sulphur springs are so frequently resorted to. Water saturated with hydrogen sulphide and carbon dioxide is usually not objected to by patients after the first day or two of its taking, and does not disagree with the stomach. *Dose*, from two to four fluidounces (60 to 120 Cc.) three or four times a day.

Hydronal. *Viferral*.—This is produced by the action of pyridine upon chloral. It is a white powder having a disagreeable taste, soluble in cold water but decomposed by hot water. Used as a hypnotic. *Dose*, fifteen to thirty grains (1.0–2.0 Gm.).

Hydroquinone. *Hydrochinone*. $C_6H_4(OH)_2$. This is one of the three isomeric diatomic phenols, being *paradioxybenzene*. It was first prepared by the dry distillation of quinic acid, but is now made from quinone by reduction with sulphurous acid, the quinone being made by oxidizing aniline with dichromate mixture ($K_2Cr_2O_7 + H_2SO_4$). It is in shining white leaflets melting at $169^\circ C$. ($336.2^\circ F.$), soluble in water, alcohol, and ether, and is used largely in photography as a developing agent. In 1877 Brieger found that hydroquinone produces in man giddiness, tinnitus aurium, and a lessening of the force and frequency of the pulse. The experiments of P. J. Martin have shown that in the frog hydroquinone causes violent convulsions, followed by paralysis and death through failure of the respiration, due to an action upon the spinal cord. In the mammal small doses produce a rise in the arterial pressure, followed by a depression; both these phenomena are apparently the result of an action of the drug upon the arterial vasomotor system, although it is probable, from the experiments of Beyer, that the toxic dose of hydroquinone paralyzes both the heart muscles and the muscle fibres in the coat of the arterioles. The bodily temperature is lowered by large doses of hydroquinone, and, according to the experiments of Martin, this is chiefly due to an increase of heat dissipation, and is, therefore, probably the result of a vasomotor paralysis.

Hydroquinone is also a distinct antiseptic, but, according to Antaeff, when it is mixed with a solution of urea the latter principle undergoes rapid decomposition. The influence of hydroquinone upon the human being has been especially studied by Silvestrini and Picchini, and by Gaetano Traversa. (*France Méd.*, May, 1890.) According to these authorities, it is a prompt antipyretic, producing depression of temperature in fever, the reduction beginning in half an hour, and reaching its maximum in an hour and a half. Usually the antipyretic action is not accompanied by disagreeable symptoms, although after the larger dose excessive sweating, chills, and some nervous disturbances have been noted. It was found in the experiments of Martin that the fall of temperature is due to an increase of heat dissipation; this is confirmed by the observation of Traversa, that the peripheral temperature may rise as much as two degrees, although the internal temperature is depressed. The excretion of urea is said to be diminished. Hydroquinone has been used with asserted good results in *infectious fevers*, and in *acute articular rheumatism*; also as

a gastro-intestinal disinfectant. According to Forster, a 1 per cent. solution will arrest putrefaction and alcoholic fermentation. *Dose*, three to eleven grains (0.2–0.71 Gm.).

Hydroxylamine Hydrochloride. $NH_2.OH.HCl$. The free base is known only in solution, and is unstable. The crystalline hydrochloride forms colorless hygroscopic crystals similar to ammonium chloride in appearance, soluble in an equal weight of water, also in glycerin and in fifteen parts of alcohol. In 1888 Binz found that this substance caused in the lower animals stupor, convulsions, and a destruction of the red blood corpuscles, of such character that their hæmoglobin was reduced to methæmoglobin or even to hæmatin. In 1889 L. Lewin of Berlin, further investigated the subject, confirming in part the results obtained by Binz, and showing that the poison acts both upon the dead and living blood, and that its action upon the corpuscle is probably due to its decomposition, and the liberation of nitric or nitrous acid. In 1889 John Fabry (*Arch. de Derm. et de Syph.*, tome ii, 1889) found that a 10 per cent. solution is exceedingly irritating to most human skins, producing intense redness, violent burning, sweating, and not rarely vesication. Some skins will not bear a 1 per cent. solution, so that it is not safe in any new case to use a solution stronger than this. The substance was employed by Fabry, and since then by other clinicians, as an agent to replace pyrogallol and chrysarobin in the treatment of skin diseases, while it would offer the advantage of being colorless, and not staining the skin, linen, etc. It has been used in *chronic psoriasis*, in *scabies*, in *lupus*, *herpes tonsurans*, *parasitic syphilis*, etc., with asserted excellent results, though Groddeck condemns it as being too irritating and liable to produce constitutional symptoms, and inferior in its healing powers to chrysarobin and pyrogallol. The solution of hydroxylamine hydrochloride may be prepared with alcohol or water, but should always be rubbed up with prepared chalk to neutralize any excess of acid.

Hydrozone.—This name is applied commercially to an aqueous solution of hydrogen dioxide, said to be three times the strength of the official solution. It is used for the same purpose as solution of hydrogen dioxide.

Hygrophila. *Br. Add.*—The dried herb including the root of *Hygrophila spinosa*, T. And. (*As-teracantha longifolia*, Nees). *Br. Add.* (Fam. Acanthaceæ.) This species of *Hygrophila* has long been used in India as a diuretic in the treatment of *dropsies*, especially where there is hepatic obstruction, and also as a popular *aphrodisiac*. In Southern India the root is an article of commerce, but in Bombay the seeds are commonly employed. By means of petroleum benzin C. H. Warden obtained from the roots a crystalline principle (*Phg. Ind.*, vol. 3). The decoction of *hygrophila* (*Decoctum Hygrophilæ*, *Br. Add.*), two ounces of the root with three pints of water boiled to a pint, is given in *doses* of one-half to two fluidounces (15 to 60 Cc.).

Hypericum. *Hypericum perforatum*, L. *St. John's Wort*. *Millepertuis*, *Casse-diable*, Fr. *Johanniskraut*, Harthen, G. (Fam. Hypericaceæ.)—A perennial herb, abundant both in Europe and in this country. It has a peculiar balsamic odor, which is rendered more sensible by rubbing or bruising the plant. Its taste is bitter, resinous, and somewhat astringent. It imparts a yellow

color to cold water, and reddens alcohol and the fixed oils. Its chief constituents are volatile oil, a resinous substance, tannin, and coloring matter. This latter, known as *hypericum red*, is a reddish resin, smelling like the flowers, soluble in alcohol, ether, ethereal and hot fatty oils, coloring the solution from wine red to blood red. It is soluble in alkalis with green color, and gives yellow precipitates with the alkaline earths and metallic salts. As a medicine it was in high repute among the ancients and the earlier modern physicians. Among the complaints for which it was used were *hysteria*, *mania*, *intermittent fever*, *dysentery*, *gravel*, *hemorrhages*, *pectoral complaints*, *worms*, and *jaundice*; but it was, perhaps, most highly esteemed as a remedy in *wounds* and *bruises*, for which it was employed both internally and externally. It probably has somewhat analogous power to the turpentine. It formerly enjoyed great reputation for the cure of demoniacs, and the superstition still lingers among the vulgar in some countries. At present the plant is scarcely used except as a domestic remedy. The summits were given in the dose of two drachms or more. A preparation, *oleum hyperici* or *red oil*, made by macerating four ounces of the tops in a pint of olive oil, is still used in many families for bruises.

Hypnal.—*Chloralhydrate antipyrine*, $C_{11}H_{12}N_2O.CCl_3.CH.(OH)_2$, results by rubbing together 188 parts of antipyrine and 165.5 parts of hydrated chloral and crystallizing out the product. It forms colorless crystals melting at $67^\circ C.$ ($152.6^\circ F.$).

Hypnone.—*Phenyl-methyl-ketone*, $C_6H_5.COCH_3$, is obtained by the dry distillation of a mixture of calcium acetate and calcium benzoate; colorless or yellow liquid of oily consistency, boiling at $198^\circ C.$ ($388.4^\circ F.$).

Hypnopyrin.—This substance, which was brought forward by Bolognesi and Charpentier (*R. T.*, July, 1902), is said to be a derivative of quinine, although some French writers state that it is simply a mixture of undetermined quinine salts. It occurs in white, bitter needles, effervescing and turning yellow in the air, soluble in eight times its weight of cold water and very soluble in hot water and alcohol. In dose of thirty grains it is said to produce cinchonism. It is alleged that it is a rapid, efficient analgesic, and that as an antipyretic it produces a gradual fall of temperature without sweating; further antirheumatic properties are attributed to it. It is said to be harmless. *Dose*, four to eight grains (0.26–0.5 Gm.), given hypodermically.

Hyracum.—The dried excrement of *Hyraz capensis*, of South Africa. It is rather hard, tenacious, of a blackish-brown color, and in taste and odor not unlike castor. Schrader has found in it stearin and gum-resin soluble in absolute alcohol. (See *A. J. P.*, 1879, 363.) See Léon Soubeiran (*J. P. C.*, xxix. 378). E. D. Cope states that a similar substance is found in fissures of the rocks in New Mexico, and is probably a fecal and renal deposit of the wild rat, *Neotoma*.

Hyrhol. *Hydrargyrum Colloidale*. *Colloidal Mercury*. *Colloïdales Quecksilber*, G.—In dull black, porous pieces forming a dark, neutral solution with water, which is not corrosive. It turns silver-gray when heated or upon the addition of alkalis and certain acids. Globules of mercury form when it is rubbed alone, in a mortar, and it should first be mixed with water if it is desired to make it into an ointment. It is said to contain from 70 to 80 per cent. of mercury.

Hyssopus. *Hyssopus officinalis*, L. *Hyssop*. *Hysope*, Fr. *Isop*, *Ysop*, G.—This is a European labiate plant, whose flowering summits and leaves have been used in medicine. They have an agreeable aromatic odor, and a warm, pungent, bitterish taste, due to the presence of a volatile oil. This oil is colorless or greenish yellow, of peculiar odor, sharp camphor-like taste, and neutral reaction. It has a sp. gr. from 0.88 to 0.98, distills between 142° and $162^\circ C.$ (287.6° – $323.6^\circ F.$), and is soluble in its own bulk of alcohol of 0.85 sp. gr. Hyssop is a warm, gently stimulant aromatic, applicable to the same cases as the other labiate plants.

Iberis. *Iberis amara*, L. *Bitter Candytuft*.—A small European herbaceous cruciferous plant. The leaves, stem, and root are said to possess medicinal properties, but the seeds are most efficacious. The plant appears to have been employed by the ancients in *rheumatism*, *gout*, and other diseases. In large doses it is said to produce giddiness, nausea, and diarrhoea, and to be useful in *cardiac hypertrophy*, *asthma*, and *bronchitis*, in doses of from one to three grains (0.065–0.2 Gm.), of the seed. (*Prov. M. S. J.*)

Ibogaine.—From a plant known as *iboga*, indigenous to the region of the Congo, Dybowski and Landrin have isolated an actively toxic alkaloid which is said to cause hallucination, paresis, and death by the paralysis of the respiratory muscles. (*S. M.*, Dec. 1901.)

Ichthoform.—This is said to be obtained by the action of formaldehyde upon the products of sulphonization of ichthyl hydrocarbons, and to be superior to iodoform as an antiseptic. Externally it has been used by Unna, and in skin diseases is superior to the ordinary formaldehyde preparations. He asserts that it softens rather than hardens the skin. It has also been employed as an intestinal antiseptic in doses of fifteen to thirty grains (1–2 Gm.) three to four times a day.

Ichthyocolla. *U. S.* 1890. *Isinglass*. *Colla Piscium*, P. G. *Fish-Glue*. *Ichthyocolle*, *Colle de Poisson*, Fr. *Hausenblase*, *Fischleim*, G. *Colla di Pesce*, It. *Caula de Pescado*, Sp.—Isinglass is a gelatinous substance prepared from the sounds or swimming bladders of many species of fish in various parts of the world, but is chiefly procured from the Volga and other streams of Southern Russia, in which are taken annually enormous numbers of the *Acipenser Huso*, or *beluga*, the *Acipenser ruthenus*, or *sterlet*, the *Acipenser Sturio*, or common sturgeon, and the *Acipenser stellatus* or starred sturgeon. The air bags, having been split open, cleansed, and dried, are known in commerce by the name of *staple isinglass*, which is divided into the *long* and the *short staple*. Sometimes the membranes are dried in a flat state, or simply folded, and then receive the name of *leaf* or *book isinglass*. The scraps or fragments of these varieties, with various other parts of the fish, are boiled in water, which dissolves the gelatin, and upon evaporation leaves it in a solid state. This is called *cake isinglass*, from the shape which it is made to assume. It is sometimes, however, in globular masses. Of these varieties, the long staple and the finest book isinglass are the best. One hundred grains of this isinglass dissolve in ten ounces of water, forming a tremulous jelly when cold, and yield but two grains of an insoluble residue. That in cakes is brownish, of an unpleasant odor, and employed only in the arts. Inferior kinds,

with the same commercial titles, are said to be prepared from the peritoneum and intestines of the fish. An inferior Russian product, known in English commerce by the name of *Samovey isinglass*, is procured, according to Pereira, from the *Silurius glanis*. It comes, like the better kind, in the shape of leaf, book, and the short staple. Isinglass, little inferior to the Russian, is made in Iceland from the sounds of the cod and ling. It is said also to be prepared by the fishermen of Newfoundland. We receive from Brazil the air-bladders of a large fish, prepared by drying them in their distended state. They are oblong, tapering, and pointed at one end, bifid with the remains of their pneumatic duct at the other, and of a firm consistence. The *Brazilian isinglass* is inferior to the Russian. Considerable quantities of isinglass are manufactured in New York and New England from the sounds of the *hake* (*Gadus merluccius*) and of the weak-fish (*Otolithus regalis*). This *American isinglass* is in thin ribbons several feet in length, and from an inch and a half to two inches in width. One hundred grains dissolve almost entirely in water, leaving but two grains of insoluble membrane, and form a jelly when cold with eight ounces of water; it retains a fishy taste and odor, which render it unfit for culinary or medicinal purposes. The sounds are dried whole, or merely split open, and vary much in size and texture, weighing from a drachm to an ounce. An article called *refined* or *transparent isinglass* is made by dissolving the New England isinglass in hot water, and spreading the solution to dry on oiled muslin. It is in very thin, transparent plates, and is an excellent glue, but retains a strong fishy odor. In India and China the swimming bladders of various species of fish furnish the so-called Indian and Chinese isinglass. At the present writing, 1905, all forms of isinglass are comparatively little used, their place being supplied by various brands of gelatin produced from fresh bones. (See *Gelatinum*, p. 576.)

In its purest form it is "in separate sheets, sometimes rolled, of a horny or pearly appearance; whitish or yellowish, semitransparent, iridescent, inodorous, insipid; almost entirely soluble in boiling water and in boiling diluted alcohol. A solution of Isinglass in 24 parts of boiling water forms, on cooling, a transparent jelly." *U. S.* 1890. The inferior kinds are yellowish and more opaque. In cold water it softens, swells up, and becomes opalescent. Boiling water entirely dissolves it, with the exception of a minute proportion of impurities, amounting, according to Hatchet, to less than 2 per cent. The solution on cooling assumes the form of a jelly, which consists of pure gelatin and water. Isinglass is in fact the purest form of *gelatin* with which we are acquainted, and may be used whenever this principle is required as a test. It is insoluble in alcohol, but is dissolved readily by most of the diluted acids, and by alkaline solutions. It has a strong affinity for tannin, with which it forms an insoluble compound. Boiled with sulphuric acid, it is converted into a peculiar substance, called *glycocoll* or *sugar of gelatin*, which is in reality *amido-acetic acid*, $C_2H_3(NH_2)O_2$. Its aqueous solution speedily putrefies. (See *Gelatinum*.) An ingenious adulteration has been practised by rolling a layer of gelatin between two layers of genuine isinglass. This may be detected by the disagreeable odor and taste of the adulterated drug, and the effects of

water upon it. Genuine isinglass, cut into shreds and treated with water, becomes opalescent and more opaque than before; while the shreds, though they soften and swell, remain unbroken, and when examined by the microscope are seen to be decidedly fibrous. Gelatin, on the contrary, when similarly treated, becomes more transparent than before; the shreds are disintegrated, and the structure appears amorphous under the microscope. In the adulterated article both these characters are presented in layers more or less distinct. (*P. J.*, ix. 505.) Moreover, Redwood and Letheby observed that the ash of true isinglass does not exceed 0.9 per cent., while glue contains from 2 to 4 per cent. of ash. An adulterated isinglass would therefore yield more ash than the normal. A *false isinglass* has been imported into England from Para, in Brazil, consisting of the dried ovary of a large fish. It has somewhat the form of a bunch of grapes, consisting of ovoid or roundish masses attached by a footstalk to a central axis. It is not gelatinous, and is unfit for the purposes to which isinglass is applied. (*A. J. P.*, xxv. 144.) For table showing value of different kinds of European isinglass, see *P. J.*, 1884, p. 900.

Medicinal Properties and Uses.—Isinglass has no peculiar medicinal properties. It may be given internally, in the form of jelly, as a slightly nutritive article of diet, but it has no advantage over the jelly made from calves' feet. Three drachms impart sufficient consistency to a pint of water. It is employed for clarifying liquors, and imparting lustre to various woven fabrics. Added in small quantities to vegetable jellies, it gives them a tremulous appearance, which they lack when unmixed. As a test of tannin it is strongly recommended by Wm. T. Wenzell, who uses it instead of hide powder in the estimation of tannin. (*A. J. P.*, 1894, 447.)

Isinglass plaster or court plaster (*Emplastrum Ichthyocolle*, *U. S.* 1890) was very properly dropped in the Eighth Decennial revision. The process of 1890 is as follows: "Isinglass, *ten grammes* [or 154 grains]; Alcohol, *forty grammes* [or 1 ounce av., 180 grains]; Glycerin, *one gramme* [or 15½ grains]; Water, Tincture of Benzoin, each, a *sufficient quantity*. Dissolve the Isinglass in a sufficient quantity of hot Water to make the solution weigh *one hundred and twenty grammes* [or 4 ounces av., 102 grains]. Spread one-half of this, in successive layers, upon taffeta (stretched on a frame), by means of a brush, waiting after each application until the layer is dry. Mix the second half of the Isinglass solution with the Alcohol and Glycerin, and apply it in the same manner. Then reverse the taffeta, coat it on the back with Tincture of Benzoin, and allow it to become perfectly dry. Cut the plaster in pieces of suitable length, and preserve them in well-closed vessels. The above-directed quantities are sufficient to cover a piece of taffeta *thirty-eight centimeters* [or about 15 inches] square." *U. S.* 1890.

Ichthylol. Ammonium Ichthylol-Sulphonate. $C_{28}H_{36}S_3O_6(NH_4)_2$.—The ichthylol preparations are obtained by the dry distillation of the bituminous shale of the Tyrol. The ichthylol salts are the salts of *ichthylol-sulphonic acid*, $C_{28}H_{36}S_3O_6H_2$, which is obtained by the treatment of the raw ichthylol distillate with sulphuric acid, and subsequently neutralizing with sodium or ammonium carbonate. Under the name *ichthylol* is ordinarily understood the *ammonium ichthylol-sulphonate*, $C_{28}H_{36}S_3O_6(NH_4)_2$. This is a reddish-brown

syropy liquid, of a bituminous odor and taste, puffing up considerably and carbonizing when heated, and upon continued incineration volatilizing without residue. Water, or a mixture of equal volumes of alcohol and ether, dissolves it to form a clear red-brown liquid of a faintly acid reaction. Pure alcohol or ether dissolves it only partially; petroleum benzin takes up only a small quantity. Upon the addition of hydrochloric acid to the aqueous solution a dark resinous mass is precipitated, which when separated is soluble in ether and in water, but is again thrown out from the latter solution by hydrochloric acid or sodium chloride. Treated with potassium hydroxide solution, ichthyol develops an odor of ammonia, and the mixture dried and burnt yields an hepatic coal, which with hydrochloric acid gives off hydrogen sulphide. The ammonium ichthyolate loses upon drying in a water bath at least half its weight. The sodium ichthyol is a dark tar-like substance of an alkaline reaction, perfectly soluble in water. Both preparations combine with fat and vaseline in all proportions and are very rich in sulphur, containing, it is said, 10 per cent. According to Baumann, they have a great affinity for oxygen, and are powerful reducing agents. The ichthyol sulphonates of lithium, zinc, and mercury have also been prepared.

Odorless ichthyol has been made by treating ichthyol with hydrogen dioxide. It is questionable, however, whether the removal of the odorous constituents does not impair the therapeutic activity of the ichthyol.

Medicinal Properties.—So far as is known, ichthyol has little or no general action, although it has been used to some extent internally in *rheumatism* and *tuberculosis* and by Unna in *lepra*. As an external application it is much used. Applied in the pure form to the sound skin, it produces irritation and burning. Peculiar alterative properties are attributed to it, and also the power of penetrating through the skin, so that it has been used with alleged extraordinary success as a local alterative and anodyne discutient in *chronic eczema*, *chronic urticaria*, *acne*, *intertrigo*, *lupus*, and *lepra* and various ulcerations of the skin, in *lymphatic enlargements*, for the softening and dispersion of *lipomas*, in *burns*, *frost bites*, *sprains* and *contusions*, and in almost every form of *subacute* or *chronic gout* or *rheumatism*. When the skin is not destroyed or greatly inflamed the application should be made of the full strength or as a 50 per cent. ointment. In the various skin diseases or ulcerations the strength of the lotion or ointment may vary from 1 to 50 per cent. For internal administration, H. Wyatt (*P. J.*, xxi, 1891, 929) recommends the evaporation of the ichthyol on a water bath and the formation of the residue into pills. He also made a good combination by adding 15 grains of *magnesia* (made into a milk with 90 minims of water) to 120 grains of ichthyol and evaporating over a water bath to a pilular consistence. Latteux has found ichthyol to be an active germicide. (*Journ. de Méd.*, Paris, April, 1892.) *Dose*, five to ten minims (0.3–0.6 Cc.).

Ichthyol Albuminate. Ichthalbin.—This is a greenish-brown powder, insoluble in water and acid solutions, soluble in alkaline solutions, odorless, almost tasteless. It is prepared by precipitating *egg albumin* with ichthyol and prolonged washing of the precipitate until the ichthyol odor and taste are removed. It is stated to

contain about 75 per cent. of ichthyol. It is not toxic, and when given internally, even in large doses, produces little or no irritation of the gastro-intestinal tract. It is affirmed that as an internal remedy it is practically ichthyol, and as such is useful in various conditions connected with wide-spread vascular dilatation, in *syphilis*, in *struma*, and in other states of lowered nutrition. *Dose*, from fifteen to thirty grains (1.0–2.0 Gm.) three times a day, best taken in capsules; or in the case of young children it should be mixed with chocolate.

Igazol.—This substance, which is said to be a combination of formaldehyde or tri-oxy-methylene (paraformaldehyde) and iodine, has been employed to a considerable extent in the treatment of *tuberculosis*. According to the method of Preisach the fumes of four grammes are daily liberated in a small room containing patients; the results are some diminution of cough and expectoration. (*Ungar. med. Presse*, vol. vi, 490.)

*Ignatia. U. S. 1880. Bean of Saint Ignatius. Semen Ignatiæ, Faba Ignatii, Faba Sancti Ignatii, Lat. Fève igasurique, Fève de Saint Ignace, Fr. Ignatiusbohne, Bittere Fiebernuss, Ignazbohnen, G. Fava di Santo Ignazio, It. Haba de Santo Ignacio, Sp.—Strychnos Ignatia, Berg., Ignatia amara, L. f., is a tree of the fam. Loganiaceæ, of middling size, with numerous long, cylindrical, glabrous, vine-like branches, which bear opposite, nearly sessile, oval, pointed, entire, and very smooth leaves. The flowers are long, nodding, white, tubular, fragrant, and arranged in short, axillary racemes. The fruit is of the size and shape of a pear, with a smooth, whitish, ligneous rind, enclosing about twenty seeds, embedded in a dry medullary matter, and lying one upon the other. The seeds are the part used. The tree is a native of the Philippine Islands, where the seeds were highly esteemed as a medicine, and, having attracted the attention of the Jesuits, were honored with the name of their founder. Flückiger and Arthur Meyer have found that the seed has a close structural analogy to *nux vomica*. (*P. J.*, 1881, 1.)*

The seeds are about an inch long, rather less in breadth, still less in thickness, convex on one side, obscurely angular, with two, three, or four faces on the other, and marked at one end with a small depression indicating their point of attachment. They are externally of a pale brown color, apparently smooth, but covered in fact with a short down or efflorescence, which may be removed by scraping them with a knife. They are somewhat translucent and their substance is very hard and horny. They have no odor, but an excessively bitter taste. They were officially described as "about an inch and a fifth (3 Cm.) long, oblong or ovate, irregularly angular, dull brownish or blackish, very hard, horny; fracture granular, irregular; the albumen somewhat translucent, enclosing an irregular cavity with an oblong embryo; inodorous; very bitter." *U. S. 1880.* To Pelletier and Caventou they yielded the same constituents as *nux vomica*, and, among them, 1.2 per cent. of strychnine and 0.5 per cent. of brucine. J. M. Caldwell found strychnine and brucine, combined with igasuric acid, a volatile principle, extractive, gum, resin, coloring matter, fixed oil, and bassorin, but no starch or albumen. (*A. J. P.*, 1857, 298.) Flückiger, on the other hand, found 1.78 per cent. of nitrogen, corresponding to about 10 per cent. of albuminoid matter. (*Pharmacographia*, 443.) In consequence of the relatively

larger proportion of strychnine which they yield, they have been used instead of nux vomica, in the preparation of that alkaloid, when their cost would permit of the substitution, but the nux vomica bean has been imported in such large quantities, and is now so low in price, that the ignatia bean is rarely used. The medicinal uses are those of nux vomica.

ABSTRACTUM IGNATIE. U. S. 1880. *Abstract of Ignatia*.—"Ignatia, in No. 60 powder, two hundred parts [or four ounces av.]; Sugar of Milk, recently dried and in fine powder, Alcohol, Water, each, a sufficient quantity, to make one hundred parts [or two ounces av.]. Mix Alcohol and Water in the proportion of eight parts [or six fluidounces] of Alcohol to one part [or five fluidrachms] of Water, and, having moistened the Ignatia with one hundred parts [or two fluidounces] of the menstruum, pack firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, until the Ignatia is exhausted. Reserve the first one hundred and seventy parts [or three and one-half fluidounces] of the percolate, distil off the alcohol from the remainder, and mix the residue with the reserved portion. Place the mixture in an evaporating dish, and, having added fifty parts [or one ounce av.] of Sugar of Milk, cover it with a piece of thin muslin gauze, and set aside in a warm place where the temperature will not rise above 50° C. (122° F.), until the mixture is dry. Lastly, having added enough Sugar of Milk to make the mixture weigh one hundred parts [or two ounces av.], reduce it to a fine, uniform powder. Preserve the powder in a well-stopped bottle." The yield of extract is usually about 10 per cent. The dose of abstract is from one-half to one and a half grains (0.032-0.096 Gm.).

A tincture of ignatia equivalent to the U. S. 1880 preparation may be made by dissolving sixty grains of dry alcoholic extract of ignatia in a mixture of fourteen fluidounces of alcohol and one and a half fluidounces of water. Dose, from five to fifteen minims (0.3-0.9 Cc.).

Ilex. *Holly*. *Houx*, Fr. *Stechpalme*, *Christdorn*, G.—Several species of *Ilex* (Fam. *Ilicaceæ*) are employed in different parts of the world. The *I. aquifolium*, L., or common *European Holly*, is usually a shrub, but in some places attains the magnitude of a middling-sized tree. The viscid substance called *bird lime* is prepared from the inner bark. The leaves, which are of a bitter, somewhat austere taste, were formerly much esteemed as a diaphoretic, and in the form of infusion were employed in *catarrh*, *pleurisy*, *small-pox*, *gout*, etc. At one time they enjoyed a brief reputation in France as a cure for *intermittents*. They were used in powder, in the dose of a drachm two hours before the paroxysm, and this dose was sometimes repeated frequently during the apyrexia. Their febrifuge virtues are said to depend on a bitter principle, *ilicin*. Labourdais obtained this principle by boiling a filtered decoction of holly leaves with animal charcoal, allowing the charcoal to subside, washing it, then treating it with alcohol, filtering off the alcoholic solution, and evaporating it to a syrupy consistence. The liquid thus obtained was very bitter, and, on being allowed to evaporate spon-

taneously, yielded an amorphous substance, having the appearance of gelatin, which was the principle in question. (See *A. J. P.*, xxi. 89.) A yellow coloring substance called *ilexanthin*, and a peculiar acid called *ilicio acid*, have been obtained by F. Moldenhauer. *Ilexanthin* is obtained in the following manner. The leaves are exhausted with alcohol, the alcohol is distilled off, and the residue set aside for several days. A sediment forms, which is separated from the mother liquor, treated with ether to remove the chlorophyll, and then purified by repeated solution in alcohol and crystallization. The composition of *ilexanthin* is $C_{17}H_{22}O_{11}$. It crystallizes in yellow needles, which change color at 185° C. (365° F.), melt at 198° C. (388° F.), and at 214° C. (417° F.) boil with decomposition, and are not sublimable. It is insoluble in ether, but soluble in alcohol. In cold water it is almost insoluble; but hot water dissolves it freely, and deposits it in crystals on cooling. (*Chem. Cb.*, 1857, 766.) The berries are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels, and sometimes excite vomiting. Their expressed juice has been used in *jaundice*.

Ilex opaca, Soland., or *American holly*, is a middling-sized evergreen tree, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It is so similar to the European plant that it has been by some writers considered as the same species. The berries, examined by D. P. Pancoast, were found to contain tannin, pectin, two crystallizable organic principles, and salts of potassium, calcium, and magnesium. One of the crystallizable principles was inodorous and tasteless, the other inodorous but intensely bitter. The latter was obtained by a treatment similar to that of Labourdais, above described; but, after the evaporation of the tincture to a syrupy consistence the process was continued by adding potassium carbonate and afterwards ether, and agitating briskly. The ethereal solution, rising to the surface on repose, was separated, and allowed to evaporate spontaneously. Crystals of the bitter principle were deposited. This is probably pure *ilicin*. (*A. J. P.*, xxviii. 314.) Walter A. Smith (*A. J. P.*, 1887, 1668) obtained a resin soluble in alcohol by the ether extraction, and in the portion of this soluble in water he obtained evidences of a glucoside. This species is said to possess the same medicinal properties as *I. aquifolium*, L.

Ilex Paraguensis, A. St.-Hil., the *I. Maté* of St.-Hilaire, yields the celebrated *Paraguay tea*, so extensively consumed as a beverage in the interior of South America. It is a small tree or shrub growing wild along the streams in Paraguay, and also cultivated for the sake of its leaves, which are the part used. These are stripped from each plant every two or three years. The period of their collection extends from December to August, sometimes beginning earlier but never continuing later. Companies are formed who penetrate far into the forest at a distance from the settlements, and devote a long time to the collection and preparation of the leaves. These are first dried by exposure to heat, and are then reduced to powder more or less fine, which is kept for several months protected from moisture, and then packed in sacks and delivered to commerce. (*A. Demersay, Ann. Thér.*, 1868, 72; see also *Pharm. Rec.*, May, 1891.) They have a balsamic odor and bitter taste, and

are usually at first disagreeable to the palate. They have a pleasant and corroborant effect upon the stomach, but, when largely taken, cause purging and vomiting. They are used in the form of infusion, which is prepared from the entire leaves as we prepare tea; or, under the name of *cha maté*, a fine powder is put in a cup of hot water by the drinker, and after a moment's stirring, the fluid is sucked up by means of a tube expanded below, and pierced with fine holes, so as to strain out the powder. They contain, besides other substances, a peculiar tannin and the alkaloid caffeine in variable amount. In the analysis of D. A. Strauch, the leaves yielded 0.450 of theine, 20.880 of caffeinannic acid, 2.830 of gum, 5.902 of resin, chlorophyll, and wax, 1.200 of starch, 3.361 of protein compounds, 22.148 of cellulose, 8.640 of apotheme, 3.896 of salts, 8.100 of water, with a trace of volatile oil, and some sand and extractive. (*A. J. P.*, 1868, 314.) Some fresh leaves of *Ilex Paraguensis* grown in the Cambridge Botanical Gardens were found by A. H. Allen, after drying at 100° C. (212° F.), to contain: insoluble matter, 57.94 per cent.; tannin, by lead acetate method, 15.62; tannin, by cupric acetate method, 15.66; caffeine, 1.13; total ash, 6.14; soluble ash, 3.56. (*Com. Org. Anal.*, 2d ed., iii., PART II, 527.) Some elaborate proximate analyses of maté are also published by Theodore Peckolt. (*P. J.* (3), xiv, 121.) The consumption of maté, or *yerba*, in South America is enormous. Although largely produced in the Argentine Republic, fourteen thousand tons of the leaves were in 1880 imported into that country from Brazil and Paraguay, and six thousand tons into the republic of Uruguay. For an interesting account of the method of preparation, and an elaborate analysis, see *P. J.*, vol. xvi, 1017.

The *Ilex vomitoria*, Soland. (*I. Cassine*, Walt., not L.), is a handsome evergreen shrub, growing in our Southern States, and especially abundant along the southern coast of Florida. Analysis of its leaves by Venable (*A. J. P.*, 1885, 390) gave 7.39 per cent. of tannic acid and 0.27 per cent. of caffeine. It is the *cassena* of the Indians, who formerly employed a decoction made from the toasted leaves, called *black drink*, both as a medicine and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the *Ilex Cassine*, L. (*I. Dahoon*, Walt.), have similar properties, and are also said to have entered into the composition of the black drink. The leaves of the *I. vomitoria*, Soland., known as *Yaupon* by the Indians, yielded to H. M. Smith 0.011 per cent. of volatile oil and 0.122 per cent. of caffeine. (*A. J. P.*, xlv, 217.)

***Illicium*.** *U. S. Star-Anise*.—"The fruit of *Illicium verum* Hooker filius (nat. ord. *Magnoliaceae*)."*U. S.* 1890. Of the genus *Illicium*, twelve species are recognized, of which two are found on the Atlantic coast of Southern North America, two in Hindostan, and three in China and Japan. Many of the species are possessed of aromatic properties. *I. floridanum*, Ell., *poison bay*, *sweet laurel*, a small evergreen tree or shrub with oblong-lanceolate, acuminate leaves, which grows westward from Florida along the coast bounding the Gulf of Mexico, has its bark, leaves, and probably also seed vessels endowed with a spicy odor and taste, analogous to those of anise. Another species, *I. parviflorum*, Vent. (*I. anisatum*, Bartr., not L.), a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavor closely resembling that of sassafras root. A decoction of the seeds is said to produce violent gastro-intes-

tinal irritation, followed by motor and sensory paralysis, with convulsions and death if the dose has been sufficient. E. Barral (*Revue Gén. de Olin.*, Oct. 1889) states that he has obtained a poisonous glucoside from the kernel. H. C. C. Maisch (*A. J. P.*, 1885, 280) obtained from the leaves a crystalline alkaloid to which the bitter taste is due, tannin, and a resin. In the root bark and capsules he found volatile oil and a crystalline principle, melting at 100° C., insoluble in alcohol and ether, but soluble in chloroform, and neutral to test paper. *Illicium religiosum*, Siebold (*I. anisatum*, L.), the sacred anise tree of Japan, is a small tree, twenty-five or thirty feet high, bearing small yellow and white flowers. As was pointed out by Piry in 1878, and confirmed by Bretschneider, star-anise is chiefly produced in the extreme southeast portion of China, in the provinces of Kwang-si and Kwang-tung, especially in the mountainous region between the Tso-kiang and the Yu-kiang, and also in Annam, and finds exit principally through the port of Pakhoi. Although Bentley and Trimmen give *I. anisatum*, L., as the botanical source of star-anise, yet the assertion of Bretschneider that the botanical source of the plant is unknown, led to seeds being sent from the Hong-Kong Botanical Gardens to Kew, and a successful cultivation resulted in the description by Hooker of a new species of *Illicium*, under the name of *I. verum*. (*Bot. Mag.*, t. 7005, July, 1888.) The leading features in the plant appear to be the solitary axillary globular flowers, which do not expand fully, the segments remaining convex, the inner segments being red, and the ten stamens, in which the filament forms with the connective an ovoid body. The peduncles are curved and barely half an inch in length.

Star-anise was examined by C. E. Schlegel (*A. J. P.*, 1885, p. 426), who found *saponin* in the aqueous extract; in the alcoholic extract, a crystalline principle of a strong musk-like odor, which did not show alkaloid or glucosidal reactions, and oil of star-anise.

I. religiosum, Sieb., or *shikimi*, of India, is very poisonous, causing vomiting and epileptiform convulsions, with dilated pupil and exceedingly cyanosed countenance; in it has been found by J. F. Eykman (*P. J.*, xi, 1046) a crystalline principle, for which the name of *shikimine* or *sikimin* has been proposed. (See footnote, page 1526.)

Properties.—"The fruit is pedunculate and consists of eight stellately arranged carpels, which are boat-shaped, about 10 Mm. long, rather woody, wrinkled, straight-beaked, brown, dehiscent on the upper suture, internally reddish-brown, glossy, and containing a single, flattish, oval, glossy, brownish-yellow seed; odor anise-like; taste of the carpels sweet and aromatic, and of the seeds oily. Star-anise should not be confounded with the very similar but poisonous fruit of *Illicium anisatum* Linné (*Illicium religiosum* Siebold), the carpels of which are more woody, shrivelled, and have a thin, mostly curved beak, a faint, clove-like odor, and an unpleasant taste." *U. S.* 1890. Star-anise is used principally as a source of oil of anise, which is prepared by distillation not only in Southwestern China, but also in enormous quantities in Annam, where it is enclosed in tinned vessels and sent into commerce through China.

Eykman (*P. J.*, 1885, p. 985) has shown that in the essential oil of the fruit of *Illicium religiosum*, *safrol*, $C_{10}H_{10}O_2$, is found, accompanied by *eugenol*, $C_{10}H_{12}O_2$. On the other hand,

the chief constituent of the oil of *I. verum* is anethol, $C_{10}H_{12}O$. The constituents of low boiling-point in star-anise oil, consisting of terpenes essentially, have been reported upon by the chemists of Schimmel & Co. (*Schim. Rep.*, April, 1893).¹ They find *dextro-pinene*, boiling at 157° to 163° C. (314.6°–325.4° F.), and *lavophellandrene*, boiling at from 170° to 175° C. (338°–347° F.). The medicinal properties of the oil of star-anise are similar to those of oil of anise. Sikimin is not used in medicine.²

Impatiens. *Impatiens biflora*, Walt. (*I. fulva*, Nutt.), and *I. aurea*, Muhl. (*I. pallida*, Nutt.). *Touch-me-not*. *Jewel-weed*. *Balsam-weed*.—These two species of *Impatiens* (Fam. Balsaminaceæ), the former of which is better known commonly as *Spotted Touch-me-not* and the latter as *Pale Touch-me-not*, are indigenous, annual, succulent plants, from two to four feet high, growing in low, moist grounds, and flowering in July and August. They may be known by their tender, juicy, almost transparent stems; by their yellow flowers, which in the latter species are pale and sparingly punctate, in the former are deeper colored and crowded with dark spots, and by their capsules, which burst elastically, and curl up with the slightest pressure. They probably possess properties similar to those of *I. Noli-tangere*, D. Don (*I. Noli-me-tangere*, Crantz), of Europe, which has an acrid burning taste, and, when taken internally, acts as an emetic, cathartic, and diuretic, though considered dangerous, and therefore little used. Ruau of Philadelphia, employed with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing yellow. The *I. Balsamina*, L., or *balsam-weed*, *touch-me-not*, etc., of the gardens resembles the other species in its effects.

Imperatoria. *Imperatoria Ostruthium*, L. *Masterwort*. *Rhizoma Imperatoriæ*, P. G. *Impératoire*,

Fr. *Meisterwurz*, Kaiserwurz, G.—An umbelliferous plant, indigenous in Southern Europe. The root has a strong odor, similar to that of angelica, and a pungent, biting, aromatic taste, attended by a flow of saliva, and followed by a glowing warmth which remains long in the mouth. E. M. Holmes (*P. J.*, March 17, 1877) noticed this root mixed with aconite in the London market, but this probably arose from carelessness, as masterwort is worth twice as much as aconite. A crystallizable, tasteless principle, called *imperatorin*, was extracted from the root by Wackenroder, and Gorup-Besanez found in the root another principle, to which he gave the name of *ostruthin*. Besides these two crystalline compounds, masterwort contains a volatile oil, composed of a hydrocarbon and an oxygenated compound, probably the aldehyde of angelic acid. (Wagner, *J. P. C.*, lxii. 283.) Jassoy (*Ap. Ztg.*, v. 150) has since investigated the substance ostruthin and gives it the formula $C_{18}H_{20}O_3$. He states that it does not contain a methoxyl group but a phenol-like hydroxyl. By fusion with potassium hydroxide, it yields along with a carbonaceous residue small amounts of resorcinol and acetic and butyric acids. By the action of bromine in chloroform solution it is changed in the presence of acid sodium carbonate into *tribromostruthin*, $C_{18}H_{19}Br_3O_3$. (Schmidt, *Pharm. Chem.*, Bd. ii., 3te Auf., 1510.) The root of masterwort was formerly considered alexipharmic, stomachic, corroborant, emmenagogue, diuretic, and diaphoretic, and was used in a wide circle of complaints with so much supposed success as to have gained for it the title of *divinum remedium*. It is, however, merely a stimulant aromatic, which in this country is unknown as a remedy. Its leaves are used as a potherb and to flavor cheese.

Incassa Poison.—This is an African ordeal bark, which has been studied by Liebreich, who found in it a very violent cardiac poison.

¹ The following table gives the distinctive characters which, according to J. F. Eykman, distinguish the oil of *Illicium religiosum* from allied oils (*P. J.*, xl. 1048):

	Ol. Anisi Vulgaris.	Oleum Feniculi.	Ol. Illici Anisati.	Ol. Illici Religiosi.
Constituents	Chiefly solid and liquid anethol.	Small quantity of terpene boiling at 190° C., and liquid and solid anethol.	Chiefly solid and liquid anethol.	Rather much of a terpene boiling at 173° to 178° C.; liquid anethol boiling at 232° to 238° C.
Melting Point	+6° to +18° C.	—2° to +18° C.	About 0° C.	Not solid when cooled to 26° C.
Specific Gravity	About 0.903.	0.94 to 0.998.	0.978.	1.006.
Molecular Rotation . .	0° to +0.6°.	+13° to +19.6°.	0° to —0.4°.	—8.6°.
Alcoholic Hydrochloric Acid.	Colorless, afterwards reddish, then pale red.	Colorless.	Colorless.	Colorless, afterwards blue.
Chloral Reagent	Colorless, afterwards yellow and brownish.	Colorless, then beautiful red.	Colorless, then beautiful red.	Colorless, afterwards dirty brown-yellow.
Ammoniacal Silver Solution.	In 24 hours no reduction.	Like ol. anisi vulgaris.	Like ol. anisi vulgaris.	Reduction in a few hours.
Hager's Reaction . . .	In alcohol, a portion of the sulphuric acid and oil mixture remains undissolved as a thick mass adhering to the sides of the tube.	Mixture of oil, sulphuric acid, and alcohol is perfectly clear.	Like ol. anisi vulgaris.	Mixture is nearly clear; separation of a little reddish-white deposit.
10 drops of oil, with 60 drops of ether and about 0.15 gramme of sodium.	Colorless; after 4 hours the mixture nearly colorless; deposit yellowish white.	Colorless; after 4 hours liquid and deposit yellow.	Colorless; after 4 hours bluish; after 4 hours liquid pale yellow, deposit yellow.	Colorless; quickly bluish; after 4 hours liquid pale yellow, deposit yellow.

² Sikimin is violently poisonous, belonging to the group of convulsants of which picrotoxin is the type. Plugge and Schutte associate in this group—*Dioscorine*, the alkaloid of *Dioscorea hirsuta*; *cicutoxin*, from *Cicuta virosa*, L.; *coriarymyrtin*, a glucoside of *Coriaria myrtifolia*, L.; *digitalisrin* and *toxicarin*, prepared by Schmiedeberg from digitalin and digitoxin; *phytolaccatoxine*, the alkaloid of *Phytolacca acinosa*; *sikimin*; *onanthaloxine*, the alkaloid obtained from the *Eranthe crocata*, L., by Pohl; *isonitroso-anilactone*, an artificial substance prepared by Holleman. (See *Archiv. Internat. d. Pharmacodyn.*, iv. 1897.)

Indelible Ink.—This is prepared by dissolving two drachms of silver nitrate and a drachm of gum arabic in a fluidounce of distilled water, colored with a little Indian ink. It is used for writing with a pen on linen and muslin. The place to be marked is prepared by being moistened with a solution of two ounces of crystallized sodium carbonate and two drachms of gum arabic in four fluidounces of water, and then dried. This alkaline solution, called *mordant*, decomposes the nitrate, and protects the cloth from the action of the free nitric acid. At the end of twenty-four hours the spot is to be washed.

Redwood of London, proposes the following indelible ink, not requiring the use of a mordant. Dissolve an ounce of silver nitrate and an ounce and a half of crystallized sodium carbonate, separately, in distilled water, and mix the solutions. Wash the precipitated silver carbonate, and, having introduced it, still moist, into a Wedgwood mortar, rub it with 160 grains of tartaric acid, until effervescence ceases. Then add strong solution of ammonia, just sufficient to dissolve the silver tartrate formed (about two fluidounces). Lastly, having mixed in half a fluidounce of archil, half an ounce of white sugar, and an ounce and a half of powdered gum arabic, add sufficient distilled water to make the whole measure six fluidounces. Soubeiran has given the following formula for indelible ink, which he considers simpler than Redwood's. Dissolve 8 parts of crystallized silver nitrate, 3 of copper nitrate, and 4 of sodium carbonate, in 100 of ammonia water, and add to the solution a little gum. The marks produced by silver nitrate on linen or muslin may be completely removed by moistening them with a solution of corrosive sublimate or of potassium cyanide in distilled water, and afterwards washing them. A better way is to moisten with tincture of iodine, rinse and treat with a solution of sodium thiosulphate. Repeat if necessary. The chemicals used are not poisonous.

Julius Guiller has devised the three following formulas for marking inks for linen. 1. Silver nitrate 11 parts; distilled water 85; powdered gum arabic 20; sodium carbonate 22; solution of ammonia 20. Dissolve the sodium carbonate in the water, rubbing the solution with the gum, and the silver nitrate in the ammonia. Mix the solutions, and gradually heat the mixture in a flask until it boils. This ink flows readily from a pen. 2. Silver nitrate 5 parts; distilled water 12; powdered gum arabic 5; sodium carbonate 7; solution of ammonia 10. The ingredients are treated as in the preceding formula, with the exception that the mixed solution is heated until it becomes of a very dark color, and is reduced about one-twentieth in volume by evaporation. This ink is suitable for marking on linen with stamps. 3. Silver nitrate 17 parts; distilled water 85; powdered gum arabic 20; sodium carbonate 22; solution of ammonia 42; copper sulphate 33. Dissolve the silver nitrate in the ammonia, the sodium carbonate in 25 parts of the water, and the gum in the remaining 60. Then mix with the soda solution, first the gum solution, and afterwards the silver solution. Lastly, add the copper sulphate. This ink has a blue instead of the dark brown color of the others. (See *A. J. P.*, 1853, 33.)

Boettger gives the following formula: 3.65 Gm. of aniline black are rubbed down in a porcelain mortar with 60 drops of concentrated hydrochloric acid, and 22 Gm. of alcohol. This solution

is mixed with a hot solution of 1.82 Gm. of gum arabic in 85 Gm. of hot water. This ink does not attack steel pens, and is not acted upon either by strong mineral acids or by alkalis. If the aniline black solution be diluted with shellac solution (21 Gm. in 85 of alcohol), an aniline black lake will be obtained, which is suited for coloring wood and leather.

Herberger recommends the following indelible ink for other purposes than marking linen. Dissolve wheat gluten, carefully freed from starch, in a little weak acetic acid, and dilute the solution with rain water, so as to have about the strength of wine vinegar. For every four ounces of the solution add ten grains of the best lamp black, two grains of indigo, and a little oil of cloves. This ink has a beautiful black color, and cannot be removed by chlorine or dilute acids.

Elsner states that an *indelible red ink* can be prepared as follows. Equal parts by weight of copperas and cinnabar, both in fine powder and sifted, are rubbed up with linseed oil with a muller, and finally squeezed through a cloth. The thick paste can be employed for writing or stamping woollen or cotton goods.

Indian Podophyllum Rhizome. *Podophylli Indici Rhizoma*, Br. Add.—The dried rhizome and roots of *Podophyllum Emodi*, Wallach. The contorted rhizome of *Podophyllum Emodi* is from a quarter to a third of an inch (six to eight millimeters) in thickness, crowded above with tuberosities, marked by depressed oval or circular scars, and giving off numerous simple rootlets from the whole of the under surface. The terminal bud is enclosed in whitish papery sheaths. The color is earthy-brown. The fracture is white, short, and mealy, or yellow and horny, exhibiting a circular arrangement of yellow vascular bundles, and bounded on the outside by a thin brown cortical layer. The rhizome of the Indian podophyllum has become a commercial article and appears to have been largely used in the making of podophyllin. The question as to the relative yield of the Indian and American plants is a matter of great importance to the manufacturer. Some years since Dymock and Hooper obtained 12 per cent. of resin from *P. Emodi*; Umney, working with very large quantities (*P. J.*, Sept. 1902), got out 11.4 per cent.; recently John Barclay (*P. J.*, lxx.) was not able to obtain a greater yield than 6.69 per cent. Umney, commenting on this, believes that of late years the Indian plant gives a much smaller product than formerly, probably on account of the time of year in which it is now dug. In regard to the therapeutic interchangeability of the two resins it has been demonstrated by the researches of Dunstan and Henry and J. C. Umney that the active substances in true podophyllin are all present in the Indian resin, but it is not assured that the proportion of these active principles is the same in the two resins. At one time it was claimed that the resin from the Indian species was more active than that obtained from the American plant, but this appears not to be correct. In the present state of our knowledge, the manufacturer is certainly not justified in putting upon the market a resin made from the Indian plant unless it is plainly marked as the Indian podophyllin. Distinguishing between the two resins has become a question of importance. The presence of a yellowish-green color does not, as has been affirmed, prove that a podophyllin is impure or of Indian origin. The test of solubility

is also uncertain. The Indian podophyllin, properly prepared, is freely soluble in alcohol. It is commonly stated that the true podophyllin will dissolve in ammonia (1 to 100). The Indian species is seemingly much less soluble in ammonia than this, but a properly prepared official resin does not always come up to this standard. E. J. Millard (*P. J.*, lx.) states that the Indian resin strikes with strong sulphuric acid an orange to red color, the official resin yellow coloration, tending to brown, but especially commends the following test:

To six grains (0.4 Gm.) of the resin in a test tube add one fluidrachm (3.75 Cc.) of diluted alcohol sp. gr. 0.920, and eight or ten drops (0.4–0.5 Cc.) of solution potash, B. P.; shake gently by rotating the test tube. In case of the Indian resin, the mixture becomes in a few seconds a semi-solid gelatinous mass, so that the test tube can be safely inverted. If this does not occur quickly, the mixture should be heated until it just begins to boil, and when cold it will be found to have gelatinized. The official resin similarly treated gives a dark fluid that shows no signs of gelatinizing even after standing for days. The Br. Add. recognizes the *Indian podophyllum resin* (*Podophylli Indici Resina*, Br. Add.) and directs it to be made by a process parallel to that given in the British Pharmacographia for the American resin. Dose, one-fourth to one grain (0.016 to 0.065 Cc.); also a *tincture* (*Tinctura Podophylli Indici*, Br. Add.); dose, five to fifteen minims (0.3 to 0.9 Cc.).

Indian Red.—A purplish-red pigment, brought from the island of Ormus in the Persian Gulf. It is red ochre, and owes its color to ferric oxide.

Indian Valerian Rhizome. *Valeriana Indica* *Rhizoma*. Br. Add.—The dried rhizome of *Valeriana Wallichii*, DC., is officially described as "crooked, about two inches (five centimetres) long and from a quarter to half an inch (six to twelve millimetres) in diameter, of a full brown color, marked with transverse ridges, and thickly studded with circular prominent tubercles, to a few of which thick rootlets still remain attached. The crown is marked by a number of bracts; the lower end is blunt. The rhizome is very hard and tough; the fractured surface is greenish brown in color." According to the analysis made by J. Lindenberg (*Ph. Z. R.*, 1886), Indian valerian root is practically identical in its composition with the European drug, containing, however, a little more volatile oil. In India this valerian seems to be chiefly used as a perfume, but there is no doubt but that it is identical in its medicinal properties with the older valerian. The Br. Add. recognizes an ammoniated tincture (*Tinctura Valeriana Indica Ammoniat*, Br. Add.), dose from one-half to one fluidrachm (1.8 to 3.75 Cc.).

Indian Yellow.—This is a pigment manufactured from a yellow substance from India, called *purree*. Purree occurs in commerce in balls, from three to four ounces in weight, which are dark brown externally and deep orange within. It has a peculiar odor, closely resembling that of castor. This circumstance gave rise to the belief that it was of animal origin, but Stenhouse found it to consist of magnesia, united with a peculiar acid, which he names *purree* (*euxanthic acid* of Erdmann), and which forms nearly one-half of the crude substance. *Purree acid* is in small crystals of a light yellow color, dissolving sparingly in cold water, quite readily in boiling water, and abundantly in hot alcohol and ether. It has at

first a sweetish and then a slightly bitter taste, and possesses, in appearance, considerable resemblance to berberine. When acted upon by boiling nitric acid, it is finally converted into trinitro resorcinol, $C_6H(NO_2)_3(OH)_2$. Heated with diluted sulphuric acid (3 per cent.) to 140° C. (284° F.), it decomposes into *euxanthon* and *glycuronic anhydride*. The *euxanthon* is recognized as *diacydiphenylene-ketone oxide*, $CO < \begin{smallmatrix} C_6H_3(OH) \\ C_6H_3(OH) \end{smallmatrix} > O$, and has been made synthetically. *Purree* or *euxanthic acid* is monobasic, and has the formula $C_{19}H_{16}O_{10} + 3H_2O$. Stenhouse concludes that *purree* is probably the juice of some plant, saturated with magnesia, and boiled down to a solid consistence.

Indigo. *Indicum*. *Pigmentum Indicum*. *Indigo*, Fr., G.—This well-known and highly important dye-stuff is obtained from various species of *Indigofera* (Fam. Leguminosæ), especially *I. tinctoria*, L., and *I. Anil*, L., and is afforded also by other plants, such as *Wrightia tinctoria*, R. Br. (Fam. Apocynacæ), *Polygonum tinctorium*, Ait. (Fam. Polygonacæ), *Tephrosia tinctoria*, Pers., *Galega tinctoria*, L., and *Tephrosia Apollinea*, Link. (Fam. Leguminosæ), etc. For an interesting account of the manufacture in Manchuria of indigo from *Polygonum chinense* see *Am. Drug.*, Aug. 1888. It does not exist ready formed, but is generated, during fermentation, from another principle existing in the plant. This principle appears to have been isolated from *Isatis tinctoria*, L. (Fam. Cruciferae), by Ed. Schunck, who has named it *indican*. Through the agency of the mineral acids, it is resolved into indigo and sugar, and perhaps the same result may take place in fermentation. *Indican* is yellow, amorphous, of a nauseous bitter taste, with an acid reaction, and readily soluble in water, alcohol, and ether. In the process of preparing indigo, the plant is macerated in water; fermentation takes place; the liquor becomes of a greenish color, and in due time is decanted; the coloring principle dissolved by the water absorbs oxygen from the air, and assumes a blue color, becoming at the same time insoluble; a gradual precipitation takes place, favored by the addition of lime water or an alkaline solution, and finally the precipitated matter, having been washed upon linen filters, is dried, shaped usually into cubical masses, and sent into market. It is of an intensely blue color, but assumes a coppery or bronze hue when rubbed by a smooth hard body, as the nail. Heated to 287.7° C. (550° F.), it emits a reddish-violet vapor, which condenses in minute crystals. It is insoluble in water or alcohol, but is readily dissolved by concentrated or fuming sulphuric acid, because of the formation of *monosulphindigotic* and *disulphindigotic* acids, of which the first is difficultly soluble in water and the second easily soluble. The sodium salt of this latter constitutes the *indigo-carmin* of commerce. Indigo is soluble in chloroform, aniline, oil of turpentine, paraffin, phenol, and benzene. By deoxidizing agents it is deprived of its blue color, which it recovers by exposure to the air, in consequence of the absorption of oxygen. Such is the case with the acid sulphites, and in a less degree with sulphurous acid. Certain volatile oils are said to have the same effect when boiled with tincture of indigo, as the oils of turpentine, pepper-mint, lavender, juniper, savine, or sage. (*J. P. C.*, 1859, 399.) Its reduction and decolorization by glucose is the basis of one of the most delicate

tests we have for diabetic sugar in urine. Chlorine also destroys the blue color. For modes of testing the value of any specimen of indigo, see Sadtler's *Industrial Organic Chemistry*, 443. The most important of the methods for the determination of the indigo blue may be summarized under three heads,—viz., oxidation methods, reduction methods, and sublimation of the pure indigo blue from the commercial product. A table of analyses of commercial samples with results according to the several methods above referred to will be found in Allen, *Com. Org. Anal.*, 2d ed., iii. 311.

The artificial production of indigo has been the subject of much investigation and effort in recent years. The problem was successfully solved by A. von Baeyer of Munich, who proposed several methods capable of commercial utilization.

One method is to start with *cinnamic acid*, $C_9H_8O_2$, made artificially from benzaldehyde, which is changed into *ortho-nitro-cinnamic acid*, $C_9H_7NO_4$, and this by the intervention of the di-bromine derivative into *ortho-nitro-phenylpropionic acid*, $C_9H_8NO_4$, and this by the action of alkalies in the presence of reducing agents, like grape sugar or xanthogenates, is converted directly into *indigo blue* ($C_{16}H_8NO_2$).

A second method was by the action of dilute alkalies upon a solution of *o-nitro-benzaldehyde* in acetone according to the reaction

A method of Heumann, also successfully carried out on a large scale, is to treat *phenylglycin*, $C_6H_5.NH.CH_2.COOH$, with alkalies, and then oxidize the resulting alkaline solution, when *indigotine* is formed. These methods were all too expensive, but it has finally been made commercially, and on a scale which is fast displacing natural indigo, by the following method:

Anthranilic acid, $C_6H_4(NH_2)COOH$, which can be prepared cheaply from naphthalene, combines with *monochloroacetic acid* to form *phenyl-glycolcarboxylic acid*, $C_6H_4 \begin{smallmatrix} NH_2 \\ | \\ NH.CH_2.COOH \\ | \\ COOH \end{smallmatrix}$, and this on fusion with caustic soda yields *indoxyl*, $C_6H_4 \begin{smallmatrix} NH \\ | \\ C(OH) \end{smallmatrix} >CH$, which, in alkaline solution, is converted by atmospheric oxidation into indigo.

Synthetically prepared indigotine is now produced at a price much cheaper than refined indigo. It has several advantages, as purity, fineness of division, and ease with which it is tested.

In former years the importation of indigo from India into the United States averaged about 2,000,000 pounds, representing over 50 per cent. of the imported dye colors, the ports of entry being New York and Boston. During the year 1902 the importation of the natural indigo from India amounted to 239,580 pounds during the first six months, and ceased entirely after the month of June. It is stated that the artificial indigotine can be sold at about one-fourth the price of the vegetable dye.

Schunck first showed that all urines, whether pathological or not, contain an indigo-producing body in minute quantities. This body is commonly spoken of as *indican* in medical books. Its true chemical nature was first ascertained by Baumann, who showed that it was not a glucoside, like the indican of plants, but the potassium salt of a peculiar acid, *indoxylsulphonic acid*.

Indigo was at one time considerably used in medicine, but at present is very rarely if ever employed. It is said to produce, when taken in suffi-

cient quantity, nausea, vomiting, purging with bluish, dark stools, a dark violet or dark green color of the urine, and sometimes to cause a menstrual flux. It has been especially used in *epilepsy*, *infantile convulsions*, *chorea*, *hysteria*, and *amenorrhæa*. Dose, from twenty grains to an ounce (1.3-31 Gm.) three times a day. For further details, see 16th ed. *U. S. D.*

Inks, Colored.—The following recipes are stated by the *Boston J. Chem.* to be preferable to the solutions of aniline dyes which are now so extensively used as colored inks.

Green.—Two parts copper acetate, one part potassium carbonate, and eight parts water. Boil until half is evaporated, and filter.

Blue.—Three parts Prussian blue, one part oxalic acid, and thirty parts water. When dissolved, add one part gum arabic.

Yellow.—One part fine orpiment, well rubbed up, with four parts thick gum water.

Red.—With the aid of a gentle heat dissolve four grains of carmine in one ounce of ammonia water, and add six grains of gum arabic.

Gold.—Rub gold leaf, such as is used by book binders, with honey till it forms a uniform mixture. When the honey has been washed out with water, the gold powder will settle at the bottom, and must be mixed with gum water in sufficient quantity.

Silver.—Silver leaf treated in precisely the same manner gives a silver ink. Both these inks may, when dry, be polished with ivory.

Black.—Three ounces crushed nut-gall, two ounces crystallized ferrous sulphate, two ounces gum arabic, and twenty-four ounces water.

White.—Fine French zinc white, rubbed up with gum water to a proper consistency.

Insect Powder. *Camomille de Perse*, Fr. *Persische Bertramblumen*, G.—There are three distinct commercial varieties of insect powder, the *Caucasian*, or *Persian*, the *Dalmatian*, and the *Montenegrin*. *Persian* or *Caucasian Insect Powder*, or *Guirila*, consists of the flowers of *Chrysanthemum coccineum*, Willd., including *C. carneum*, Weber (*Pyrethrum carneum*, Bieb.), and *U. roseum*, Weber (*P. roseum*, Bieb.), also *U. Marschalli*, Aschers, growing upon the Caucasian mountains, Armenia and Northern Persia, at an elevation of about a mile. *Dalmatian Insect Powder* is the product of *Chrysanthemum cinerariæfolium* (Trev.), Bocc. (*Pyrethrum cinerariæfolium*, Trev.), and it is more powerful than the *Caucasian* powder. *Montenegrin Insect Powder* is the product of the same species, growing wild in Montenegro. It is a very superior variety. Both it and the *Dalmatian* powder come into commerce chiefly through Trieste. There are recognized three grades of the *Dalmatian* insect powder, in accordance with the condition of the flowers. The finest is that with closed leaves, the second with half closed, and the poorest variety with open leaves. In the *Montenegrin* powder the flowers are always closed or half closed. For details as to the special anatomical character of these powders, see *P. J.*, lxxvii. 474; also *J. P. C.*, 1902, xv. 409.

C. cinerariæfolium is now being cultivated on a large scale in California, and as more care is given to the preservation during drying of the color and of the volatile oil than in Dalmatia, the California product is said to be superior to the foreign drug. (*C. D.*, August, 1889; see also for method of cultivation *Reports of the Fourth U. S. Entomological Commission*, 1885.)

The insect powder of commerce varies in color from yellow, yellowish-brown, or brownish-yellow to yellowish-green, the finer qualities verging towards brown and the poorer towards green. Brilliant yellow powder should be viewed with suspicion. On microscopical examination of an insect powder, it will be found to consist of fragments of involucre scales composed of sclerenchyma, perhaps bits of stems composed of collenchymatous cells, pollen grains, fragments of the corolla and of its epidermis and papillae. The absence or scarcity of pollen in the powder shows the absence or scarcity of the flowers in the drug, while the proportion of collenchymatous tissue indicates the proportion of stems. As the activity of the insect powder resides in the flower, specimens containing little of the flowers or much of the stems should be rejected. The powder yielded by the Dalmatian plant can usually be distinguished from Persian insect powder by the following characters. The outer surface and edges of the scales of the Dalmatian flowers contain numerous hairs, consisting of a long cell with attenuated ends placed horizontally upon a one- to three-celled stalk. The Persian flowers are almost entirely glabrous, a white hoariness being found only at and near the base of the scales, and very few hairs near the apex; the hairs are of the same structure as the preceding, only the terminal cell being much longer. Sclerenchymatous cells are much more numerous in the Persian than in the Dalmatian. The so-called *Hungarian* or *Russian daisy*, probably a species of the subgenus *Leucanthemum*, has been quite largely used as an adulterant. The importance of the adulteration is increased by the fact that the Hungarian daisy appears to be entirely free from insecticidal properties. The Hungarian daisy is distinguished from the true *Pyrethrum* by the orange-yellow disk florets, by the depression of the involucre, by its prominent dark receptacle, and by the absence of pubescence and pappus. The odor is less pungent than that of the true insect flower, being more like that of *matricaria*. The difference in odor is more pronounced on infusing in warm water. The Hungarian daisy yields a powder somewhat darker in color than true insect powder. Microscopically, the Hungarian or Russian daisy differs only in the absence from the involucre and stems of the peculiar hairs seen on the scales of the true insect powder, and the presence in their place of certain hairs, consisting of from four to ten cells, and terminating with a much elongated, thin-walled, or inflated cell. There seems to be no recognizable difference between the pollen of the two plants which yield insect powder and of the Hungarian daisy. The presence of quassia, fustic, turmeric, and other adulterants may be made out by the aid of the microscope, and chrome yellow (salt of lead) chemically, but the powder of Hungarian daisy cannot be detected microscopically. According to George R. Durrant, however, the Hungarian powder yields 10 per cent. of ash, whereas true insect powder yields but 6.5 per cent. F. Dietze, after careful study, found that the best method of valuation of insect powder is based on the amount, appearance and odor of the extract obtainable by the use of petroleum spirits boiling under 55° C. With such menstruum true insect powder affords a bright yellow percolate possessing the odor peculiar to the drug. (*P. J.*, lxiv. 81.)

Insect powder does not appear to be actively poisonous to man, though it is said to cause some

confusion of head in those who sleep in close apartments where much of it is used. Upon the insects, however, which are apt to infest the person of man and animals, as well as bedding and sleeping apartments, it acts very destructively, first stupefying and then killing them. It is scattered over the person, upon the beds, about apartments, etc., and is even employed as a dressing for ulcers and wounds to prevent the formation of maggots. It also answers for preserving dried insects and plants in cabinet collections. The powder, exhausted by alcohol, is harmless to insects; its activity is therefore dependent upon some principle whose nature has not been positively determined. Trapp, and also Ivanet de Bellesme, assert that it is an alkaloid, while Rother denies that it is of such nature. (*A. J. P.*, xxv. 1857; Dragendorff, *Jahresb.*, 1876, 121.) Texton has found it to be a soft resin (*A. J. P.*, 1881, 491.) In a series of experiments, Riley has found that the fumes of the burning powder are very poisonous to insects, and for certain purposes afford a ready mode of application, but that generally an aqueous infusion is the best and cheapest preparation. It is also used now in the form of cones made by making a mass with mucilage of gum, with the addition of a small quantity of potassium nitrate. After drying, these are ignited like a pastille. Twenty-five grains stirred up in two quarts of water were sufficient to kill young cotton worms. The infusion soon spoils. The tincture and the alcoholic extract are both efficient preparations. The tincture (one part to four) has been especially recommended, diluted with ten times its bulk of water, by F. Jager, to keep off vermin from the human body. According to Maisch (*A. J. P.*, 1869, 128), it is capable of causing a vesicular eruption like that produced by the poison ivy.

Insindiyaandiya.—This substance, a remedy of the Kaffir doctors of South Africa, is a violent poison, and has been shown by E. M. Holmes to be derived from a *Bersama*, apparently identical with *B. abyssinica*, Fresen. (*P. J.*, lxxiii. 893.)

***Inula*.** *U. S.* 1890. *Inula. Elecampane.*—"The root of *Inula Helenium* Linné (nat. ord. *Compositæ*)."
U. S. 1890. *Aunée*, Fr. *Alantwurzel*, G. *Enula Campana*, It., Sp. About ninety species of this genus are recognized and distributed in Europe, Asia, and Africa, one species being naturalized in North America.

The fresh root of elecampane is very thick and branched, having whitish cylindrical ramifications, furnished with thread-like fibres. It is externally brown, internally whitish and fleshy; and the transverse sections present radiating lines. The dried root is "in transverse, concave slices or longitudinal sections, with overlapping bark, externally wrinkled and brown; flexible in damp weather; when dry, breaking with a short fracture; internally grayish, fleshy, slightly radiate, and dotted with numerous shining, yellowish-brown resin-cells; free from starch; odor peculiar, aromatic, taste bitter and pungent." *U. S.* 1890. A peculiar principle, resembling starch, was discovered in elecampane by Valentine Rose of Berlin, in 1804, who named it *alantin*; but the title *inulin*, proposed by Thomson, has been generally adopted. It differs from starch in being deposited unchanged from its solution in boiling water when the liquor cools, and in giving a yellowish instead of a blue color with iodine. It has been found in the roots of several other

plants. It may be obtained white and pure by precipitating a concentrated decoction with twice its volume of alcohol, dissolving the precipitate in a little distilled water, treating the solution with purified animal charcoal, and again precipitating with alcohol. (*A. J. P.*, xxxi. 69.) It readily dissolves in about three parts of boiling water; the levogyre solution is perfectly clear and fluid, not paste-like, but on cooling deposits nearly all the inulin. Its formula, according to Kiliani (Tollens, *Handbuch der Kohlenhydrate*, 1888, p. 202), is $3C_{12}H_{20}O_{10} + H_2O$. On prolonged heating with water, more rapidly under the influence of dilute acids, it is changed into *levulose* and reduces Fehling's solution. As in the case of starch, intermediate products can be obtained before it is completely changed into reducing sugar. Dragendorff obtained by heating with water for ten hours *metinulin*, and by heating for forty to fifty hours *levulin*, an optically inactive amorphous substance easily changing into *levulose*. Tanret, who has since investigated inulin (*J. P. C.*, 27, 449), confirms Kiliani's formula as given above. He finds associated with inulin two closely related principles: *pseudo-inulin* and *inulinin*. The first of these, to which the formula $(C_6H_{10}O_5)_{16} \cdot H_2O$ is given, forms irregular granules, very soluble in water and weak alcohol while hot, but only slightly soluble in cold water, and insoluble in cold alcohol; the second is given the formula $(C_6H_{10}O_5)_{10} \cdot 2H_2O$, and forms microscopical needles slightly soluble in cold water and weak alcohol. The amount of inulin varies according to the season, but is most abundant in autumn. Dragendorff obtained from the root in October not less than 44 per cent., but in spring only 19 per cent. A crystallizable substance was long since noticed to collect in the head of the receiver when the elecampane root is submitted to distillation with water. Similar crystals may also be observed after carefully heating a thin slice of the root, and are even found as a natural efflorescence on the surface of a root that has been long kept. They can be extracted from the root by means of alcohol, and precipitated with water. Kallen (*Ber. d. Chem. Ges.*, 1873, 1876) has found that these crystals consist chiefly of the anhydride, $C_{15}H_{20}O_2$, of *alantolic acid*, melting at $66^\circ C.$ ($150.8^\circ F.$), and that what was formerly known as *helenin* was a mixture of these with a liquid, *alantol*, $C_{10}H_{16}O$, boiling at $200^\circ C.$ ($392^\circ F.$), the true *helenin* and *alant camphor*. The crystals of *helenin*, C_8H_8O , have a bitterish taste, but no odor, and melt at $110^\circ C.$ ($230^\circ F.$). The camphor melts at $64^\circ C.$ ($147.2^\circ F.$), and in taste and odor is suggestive of peppermint.

Korab (*L. L.*, vol. i., 1885, p. 672) states that helenin is a powerful antiseptic and bactericide, one part in ten thousand of urine being sufficient to arrest putrefaction, and a few drops of a solution of this strength immediately killing the ordinary bacterial organisms, including the tubercle bacillus. He lauds it as antiseptic in surgery and has given it with alleged success internally in doses of one-third to one grain (0.021 – 0.065 Gm.) in tubercular and catarrhal diarrheas. It is also stated by J. B. Obiol (*L. L.*, April, 1886) to be an efficient local remedy in the treatment of diphtheria. Every four hours the false membrane is to be dusted over with powdered camphor, and then painted with a two per cent. solution of helenin in oil of sweet almond. It is affirmed that when the treatment was commenced on the first day of the patches the cure followed

in twenty-four hours. The helenin was also given internally. *Dose*, one and a half grains (0.096 Gm.) to children six years of age.

Medicinal Properties and Uses.—Elecampane is tonic and gently stimulant, and was employed by the ancients in *amenorrhœa* and other diseases of women, also in *phthisis*, in *drop-sies*, and in *skin affections*, in all of which diseases it was probably of no service. It has been given in powder, in the dose of twenty grains to one drachm (1.3 – 3.9 Gm.), or as a *decoction* (half ounce to the pint) in doses of one to two fluidounces (30 – 60 Cc.).

Iodal.—This substance, prepared by the action of iodine upon a mixture of alcohol and nitric acid, is decomposed by an alkali into iodoform and formic acid. Rabuteau found it to resemble hydrated chloral in its actions on animals. (*Ann. Thér.*, 1870, 98.)

Iodantifebrin. *Iodacetanilide.* $C_6H_4I.NH(C_2H_5O)$.—This occurs in rhombic flakes melting at $181.5^\circ C.$ ($358.7^\circ F.$), very slightly soluble in cold water, easily soluble in alcohol and in glacial acetic acid. In the experiments of E. Munz (*Pr. M. W.*, 1891) the physiological results following the administration of this remedy by the mouth were entirely negative, and neither iodine nor acetanilide could be recognized in the urine, the probable explanation of this being that the excessive insolubility of the drug prevents its absorption.

Iodic Acid. HIO_3 .—This is obtained by decomposing calcium iodate with sulphuric acid (*A. J. P.*, xlv. 558), or by heating iodine with nitric acid (sp. gr. 1.5), and allowing the crystals of iodic acid to separate on cooling. It has been proposed by Lutton as a remedy in chronic glandular enlargements and goitre, thirty minims (1.8 Cc.) of a 2 per cent. solution being injected into the affected part. (*Ann. Thér.*, 1874, 192.)

Its 5 per cent. solution has been highly commended as a hemostatic, also as an astringent and alterative in *gonorrhœa* and other mucous membrane infections. Pencils made of it are also said to be a very useful caustic in *chancre*s and various other *ulcers*. In using it hypodermically it is essential to have an absolutely clean syringe. In *gastro hemorrhage* it may be given in the dose of from one to two grains (0.065 – 0.13 Gm.) three times a day in milk; in *gonorrhœa*, injections of 0.05 per cent. may be employed.

Sodium iodate, a white, odorless, crystalline substance, very soluble in water, has been recommended for internal use, but is much inferior to the iodides. As a local remedy it may be useful in tubercular and other inflammations of the nose and larynx, either pure or diluted. Subcutaneous injections of from one to three grains (0.065 to 0.2 Gm.) may be safely given to reduce adenopathies, relieve rheumatic swellings and pains, and in neuritis and nervous syphilis. *Dose*, from ten to fifteen grains (0.65 – 1.0 Gm.) in milk.

Iodine Trichloride. ICl_3 .—This compound occurs in reddish-yellow crystals; very soluble in water and alcohol; rapidly decomposed with liberation of iodine and chlorine when brought in contact with organic matter. It has been especially recommended by Belfield (*B. M. J.*, Aug. 1892) as a powerful local antiseptic. A solution is prepared for medicinal use by suspending 5.5 Gm. of iodine in 22 Gm. of water, and passing in chlorine as long as it is absorbed by the well-cooled mixture. The solution contains 10 Gm. of

iodine trichloride. The strength of the solution used is 1 to 5 per cent. Gauze sterilized by boiling and immersing in 1 to 10 per cent. solution and dried is said to retain iodine trichloride indefinitely.

Iodipin.—A yellow, oily fluid, of a purely oleaginous taste, said by Winternitz (*D. M. W.*, xxiii.) to be an iodine addition product of sesame oil, and to contain 10 per cent. of iodine in chemical combination. Similar preparations have been made from lard, cacao butter, and other fats. It has been given successfully in *syphilis* and *scrofula*, in drachm doses (3.9 Gm.), three times a day, either pure or in emulsion.

Iodine.—This is affirmed to contain iodol and albumin, of which 36 per cent. is iodol. It is a yellowish, exceedingly fine, odorless, tasteless, and insoluble powder, and may be used externally for the same purposes as iodol.

Iodoformogen.—According to K. Gaab (*Ph. Centralh.*, 1898, xi. 189), iodoformogen is a chemical combination of iodoform and albumin. It occurs as a fine, loose, dry, non-conglutinating powder, having a faint acidulo-etheral odor, and being two and one-half times as voluminous as powdered iodoform. According to Kromayer (*B. K. W.*, xxxv. 1898) and to Aspegren (*Festschrift des Prof. Kapost*, Vienna, 1901), iodoformogen is more slow and continuous and certain in its local action than is iodoform. It bears sterilization at 100° C. (212° F.) without change.

Iodophenacetin. *Iodophenine.* $C_{20}H_{23}I_3N_2O_4$. To a solution of phenacetin in glacial acetic acid are added hydrochloric acid, water, and then a solution of iodine in potassium iodide. The product forms crystals resembling those of potassium permanganate, melting at from 130°–131° C. (266°–267.8° F.), with decomposition, and soluble in glacial acetic acid or alcohol. Decomposed by water. Scholvin (*O. Z.*, 1891) has found that this substance is a powerful germicide, and that it is locally very irritant, and when taken into the intestinal canal is decomposed with the liberation of iodine, and liable to produce iodine poisoning. The drug probably has no practical value.

Iodopyrine. $C_{11}H_4I.N_2O$.—This substance contains 60 per cent. antipyrine and 40 per cent. of iodine. It forms colorless crystals melting at 160° C. (320° F.), and has been recommended as an antiseptic, antipyrine, and antirheumatic, especially useful in *muscular rheumatism* and in *asthma*. It is capable of producing iodism. The dose given by Junkers was fifteen grains (1 Gm.) for adults every three or four hours. For children from 1 to 10 years old he gave one and a half to eight grains (0.096 to 0.5 Gm.). To those over 10 years he gave eight to twelve grains (0.5–0.78 Gm.). (*Th. M.*, vol. xiii. p. 604.)

Iodosyl. $C_6H_5I.OI.CO.OH$.—A bulky, amorphous powder of a deep red color, nearly odorless and having only a faint taste suggestive of that of iodine. Insoluble in water and in oils and only sparingly soluble in chloroform and ether. Although resisting decomposition by acids, alkalies, and most chemical reagents, it seems to give up iodine when brought in contact with animal tissues and so has a pronounced alterative and antiseptic action. Its medicinal uses are those of iodoform, but it has the advantage that it is odorless and in an impalpable powder. It is used as a dressing for *wounds* and *ulcers* of every description, as a local application in *nasal catarrh* and *ozæna*, in *ringworm* of the scalp, in various *cuta-*

neous affections, being especially recommended in the treatment of *corneal ulcers*. It is employed either as a dusting powder, in the form of an ointment, 2 to 10 per cent., or in that of a medicated gauze.

Iodoterpin. $C_{10}H_{16}I$.—This compound of iodine and terpin is a dark brown liquid, having the odor of turpentine, soluble in ether, benzene, and chloroform, with a specific gravity of 1.19, and a boiling point of from 165° to 175° C. (329°–347° F.). In a communication to the Twelfth International Medical Congress it was proposed by A. Lieven as a substitute for the tincture of iodine, and mixed with sterilized kaolin, 1 to 20 per cent., as an antiseptic dusting powder.

Iodozone.—This is stated to be a solution of iodine in ozone. It has been brought forward as a remedial agent by Robin, an apothecary of Bourges. (*Journ. d'Hygiène*, Aug. 1892.)

Iodylin. *Bismuth-iodo-salicylate.*—According to Israel (*Med. Wochens.*, 1902, p. 139) this substance is efficient as a substitute for iodoform.

Iodyloform.—This is a yellowish-brown insoluble powder, said to be a combination of iodine and gelatin, containing 5 per cent. of iodine, and has been used by Müller as a substitute for iodoform in *specific ulcerations*.

Ionidium. *Ionidium Marucci*.—This name has been conferred by Bancroft upon a South American plant of the fam. *Violacæ*, supposed to be the source of a medicine used with great asserted advantage, in Maracaibo and elsewhere, in *elephantiasis* and other cutaneous affections. A specimen, however, received from Bancroft, was reported by W. Hooker to be identical with the *Ionidium parviflorum* of Ventinat, which is now referred to *I. glutinosum*, Vent. The medicine is called by the Indians *cuichunchulli*, and grows at the foot of Chimborazo. It is said to be diaphoretic, diuretic, occasionally sialagogue, and in large doses emetic and cathartic. The root is the part used. For further information, see *A. J. P.*, iii. 125.

Iris. *U. S.* 1890. *Blue Flag.*—"The rhizome and rootlets of *Iris versicolor* Linné (nat. ord. *Iridæ*)."
U. S. 1890. In all the species belonging to this genus, so far as examined, the roots are more or less acrid, and possessed of cathartic and emetic properties. In Europe, *Iris fœtidissima*, L., *I. florentina*, L., *I. germanica*, L., *I. pseudoacorus*, L., and *I. tuberosa*, L., have at various times been admitted into use, and the unpeeled roots of *I. germanica* are still sold in the Indian bazaars under the name of *Irisia*. *Iris versicolor*, L., or blue flag, is found in all parts of the United States, flourishing in low wet places in meadows. The flowers afford a fine blue infusion, which serves as a test for acids and alkalies. The recent root is without odor, and has a nauseous, acrid taste, which is imparted to water by decoction, and still more perfectly to alcohol, the acrimony as well as medicinal activity is impaired by age. If cut when fresh into slices, dried at the temperature of about 100° F., then powdered and kept in bottles excluded from the air, the root retains its virtues unimpaired for a considerable time. (Andrews.) It was officially described as follows: "Rhizome of horizontal growth, consisting of joints, 5 to 10 Cm. long, cylindrical in the lower half, flattish near the upper extremity, and terminated by a circular scar, annulated from the leaf-sheaths, grayish-brown; roots long, simple, crowded near the broad end; odor slight; taste acrid and nauseous." *U. S.* 1890. D. W. Cressler found in this plant starch, gum, tannin, sugar, an

acid resin, fixed oil, and indications of an alkaloid. (A. J. P., 1881, p. 602.)

Blue flag is a cathartic and emetic, said to have been used by the Southern Indians, and may be given in doses of from ten to twenty grains (0.65–1.3 Gm.). *Iridin*, or *irisin*, of the eclectics, is an oleoresin obtained by precipitating a tincture of the root with water, and mixing the precipitate with an equal weight of some absorbent powder. Wm. E. Jenks (A. J. P., 1881, p. 601) prepares the *oleoresin of iris* by exhausting the root with alcohol sp. gr. 0.835, and distilling off the alcohol. (See also paper on the constituents of the oleoresin by W. L. Cliffe, A. J. P., 1884, p. 616.) The so-called *irisin* is undoubtedly purgative, and is generally believed to have a very decided action upon the liver, a belief which has been confirmed by the researches of Rutherford, who proved that in dogs it is a powerful stimulant to the liver and has also a decided influence upon the intestinal glands; he ranks it as less irritant to the intestines than podophyllin, and more purgative than euonymin. It may be given in pill in the dose of from three to four grains (0.20–0.26 Gm.).

The Pharmacopœia formerly recognized a solid extract (*Extractum Iridis*), made by the following process: "Iris, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until three thousand cubic centimeters [or 101 fluidounces, 3½ fluidrachms] of tincture are obtained, or the Iris is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." U. S. 1890. The dose of the extract of iris is one to two grains (0.065 to 0.13 Gm.).

The *Extractum Iridis Fluidum*, U. S. 1890 (*fluid extract of iris*), was made as follows: "Iris, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Iris is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 207 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue, on a water-bath, to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890. Dose, five to ten minims (0.3–0.6 Cc.).

Iron, Ammoniated. Ammoniated Iron. *Ferrum Ammoniatum*. Ammonio-chloride of Iron. *Ammonii et Ferri Chloridum*. Ammonium Chloride.

tum Ferratum. *Sel Ammoniac Martial*, Fr. *Eisensalmiak*, G.—This drug was formerly recognized both by the U. S. and London Pharmacopœias, which contained formulas for its preparation. (See U. S. D., 15th edition, 1568.) There is no reason to believe that the ferric chloride and ammonium chloride are chemically combined in the preparation. According to Phillips, they are in the proportion of 15 parts of the iron to 85 of the ammonium salt.

Ammoniated iron is in crystalline grains, of a fine reddish-orange color, and a sharp, styptic, saline taste. It is entirely soluble in water and diluted alcohol, is deliquescent, and should be kept in well-stoppered bottles. As procured by sublimation (*Flores martiales*, *Ens martis*), it is of a yellow color and feeble odor. It unites aperient with chalybeate properties, and is said to have been used with advantage in *amenorrhœa*, *epilepsy*, *scrofula*, *rickets*, etc.; but it is at best uncertain, and is now very seldom prescribed. Dose, from four to twelve grains (0.26–0.78 Gm.).

Iron and Bismuth Citrate. *Ferri et Bismuthi Citras*.—A solution of this so-called salt has been used in *dyspepsia*. It is made by dissolving bismuth citrate in an aqueous solution of ammonia, and adding the ferric ammonio-citrate. It is not a chemical salt. (A. J. P., xliv.)

Iron and Magnesium Citrate. *Ferri et Magnesii Citras*.—This double salt, introduced by Van der Corput, is made by dissolving two ounces of freshly precipitated ferric hydroxide in a moderately heated solution of three ounces of citric acid, and saturating the liquor with magnesium carbonate. The solution, after filtration, is evaporated by means of a water bath to a syrupy consistence, and spread on glass to dry in scales. Three and a quarter ounces of ferrous sulphate will furnish by decomposition the necessary hydroxide for three ounces of the acid. (See formula for *Ferri Hydroxidum*, p. 505.) This salt is in transparent, greenish-yellow scales, having a slightly ferruginous, somewhat acid taste. It is very soluble in water, but insoluble in alcohol and ether. Dose, from five to ten grains (0.32–0.65 Gm.). (See A. J. P., 1850, 315.)

Iron Caseinate. *Ferri Caseinas*. *Ferrum Caseinatum*. *Ferrum nucleo-albuminatum*.—One part of freshly precipitated casein, thoroughly washed, and freed from fat by treatment with ether, is mixed with 1 part of calcium carbonate and 100 parts of water. The resulting solution, after being filtered, is precipitated by a slight excess of a 1 per cent., freshly prepared solution of ferrous lactate. The precipitated iron caseinate is washed and dried and is in the form of a flesh-colored, odorless, tasteless powder, insoluble in water but soluble in weak sodium carbonate and ammonia solutions. It is recommended as a form of iron which can be readily absorbed.

Iron Peptonate. *Ferri Peptonas*. *Ferrum Peptonatum*. *Peptonate de Fer*, Fr. *Eisen Peptonat*, G.—To a solution of 2 parts of dried peptone in 200 parts of water add a mixture of 24 parts of solution of dialyzed iron (*Liquor Ferri Oxychlorati*, P. G.) and 200 parts of water, in a thin stream and while stirring constantly. A solution of caustic soda (1.5 per cent.) is added until there is produced a very weak alkaline reaction. The precipitated iron peptonate is washed rapidly with water until no reaction with silver nitrate is shown. The precipitate is drained on a wet strainer and dissolved in three parts of 25 per cent. hydrochloric acid. The solution is evapo-

rated on a water bath and spread on plates to dry at a temperature not exceeding 50° to 60° C. (122° – 140° F.). Iron peptonate, thus prepared, is in the form of shining brown scales, and contains from 24 to 25 per cent. of iron. It is slowly soluble in cold water, more quickly in hot water, and the solution is not clouded by boiling nor by the addition of alcohol. Iron peptonate, its solution, and a syrup prepared from it are used in preference to inorganic salts of iron because of the absence of injurious effects upon the teeth and mucous membrane and its deficiency in astringency. The dose is from three to ten grains (0.2–0.65 Gm.).

Liquor Ferri Peptonati.—Solution of iron peptonate is made according to the supplement of the German Pharmacopœia (1890 edition) as follows: Dried peptone, 8 Gm., is dissolved in 100 Gm. of hot water, and to the solution, when cold, are added 174 Gm. of solution of oxychloride of iron (**Liquor Ferri Oxychlorati**, P. G., sp. gr. 1.050), gradually and under constant stirring. The liquid is exactly neutralized with diluted solution of sodium hydroxide, and the precipitate washed with distilled water until the washings are unaffected by solution of silver nitrate. The precipitate is drained on a muslin strainer, mixed with 200 Gm. of syrup, then warmed and dissolved by the cautious addition of solution of sodium hydroxide (1.5 per cent.). To this solution are added alcohol, 100 Gm.; tincture of orange peel, 3 Gm.; aromatic tincture and tincture of vanilla, of each 1.5 Gm.; acetic ether, 5 drops, and sufficient distilled water to make the preparation weigh 1000 Gm. It is a transparent, reddish-brown liquid, containing about 0.6 per cent. of metallic iron, and should be protected against the light, to prevent precipitation.

Liquor Ferri-Albuminati. *Solution of Iron Albuminate.* *Eisenalbuminatlösung*, G.—Thirty-five parts of dry egg albumin are dissolved in 1000 parts of water, the solution is strained and then poured slowly in a thin stream, under constant stirring, into a mixture of 100 parts of solution of oxychloride of iron (dialyzed iron) and 1000 parts of water; the precipitate is well washed with water and then dissolved in a mixture of 3 parts of 15 per cent. solution of sodium hydroxide and 50 parts of water; 150 parts of alcohol, 100 parts of cinnamon water, and 2 parts of aromatic tincture are added to the solution with sufficient water to make the finished preparation weigh 1000 parts. It contains about 0.4 per cent. of metallic iron, and when added to alcohol should form a transparent liquid.

On slowly heating 10 Cc. of a solution (1 in 20) of iron peptonate with 2 Cc. of hydrochloric acid to boiling, the liquid at first becomes turbid, then separates in flakes, which finally dissolve.

Iron-Wood. *Ostrya virginiana* (Mill.), Willd. (*O. virginica*, Willd. *Carpinus virginiana*, Mill.) (Fam. Betulaceæ).—The wood of the hop-hornbeam is said to be tonic, antiperiodic, and alterative, and the fluidextract has been used in doses of from a half to one fluidrachm (1.8–3.75 Cc.) in *ague*.

Isarol. *Ichthyodin*.—This is a substance prepared by the action of sulphuric acid on impure ichthyol. It occurs as a brownish-red thick liquid, having an odor like that of ichthyol; containing about 9 per cent., or, when dried, 17 to 19 per cent., of sulphur. It makes a clear solution in water, and is also soluble in ten parts of 95 per cent. alcohol. It is said to be therapeutically

equivalent to ichthyol, and has been recommended on account of superior cheapness to the refined ichthyol.

Isatis. *Isatis tinctoria*, L. *Wood. Pastel*. (Fam. Cruciferae).—A biennial plant, indigenous and cultivated in Europe. The leaves have a fugitive, pungent odor, and an acrid, very durable taste; they have been used in scorbutic affections, jaundice, and other complaints, but are only valuable because of the indican present, which yields indigo blue. (See *Indigo*.) The leaves are prepared by grinding them to a paste, which is made into balls, placed in heaps, and allowed to ferment. When the fermentation is at an end, the mass falls into a coarse powder, which is wood.

Isopral. *Trichlorisopropylalcohol*, $\text{CCl}_3\text{CH}_2\text{OH}$. CH_3 .—This substance, which has been proposed as a hypnotic, occurs in microscopic prisms, melting at 49° C. (120.2° F.), readily soluble in water, alcohol, or ether, readily subliming and having a camphor-like odor and aromatic taste. Heated with alkalis for a long time it loses chlorine without the formation of chloroform. According to Impens, it is readily absorbed through the skin, subcutaneous tissue, and the digestive tract, the impression, when taken internally, being manifested in from three to five minutes. It is said, also, that a stream of air directed over warmed isopral will produce marked narcosis in the lower animals in ten or twelve minutes. It is eliminated through the kidneys chiefly as a compound glycuronic acid (*trichlorisopropylglycuronic acid*), although it is believed also to escape to some extent through the respiratory tract. According to Impens, in proportion to its narcotic influence it is only half as poisonous to the lower animals as is chloral. The dose is from ten to thirty grains (0.65–2 Gm.). In the dog the smallest dose certain to produce sleep is said to be 0.093 gramme per kilogramme, 0.6 gramme being the lethal dose.

Isopyrum. *Isopyrum thalictroides*, L. (Fam. Ranunculaceæ).—F. A. Harsten believes he has found two alkaloids, *isopyrine* and *pseudoisopyrine*, in the root of this plant. (A. J. P., xlv. 453.)

Ispaghula. *Br. Add.*—The dried seeds of *Plantago ovata*, Forsk. (*Plantago Ispaghula*, Roxb.) There are in the Indian bazaars two ispaghulas, one pinkish-white, the other brown, the pinkish-white being the official, the brown, the seeds of *P. amplexicaulis*; although both plants are found in the Punjab, the commercial supply of the seeds appears to come chiefly from Persia. The boat-shaped seeds are acute at one end, from one-tenth to one-eighth of an inch long, and have dark elongated spots on the convex side. They are odorless and tasteless and produce with water a viscid mucilage. They are used in India as a demulcent in *dysentery* and various intestinal irritations, and are also slightly laxative. On roasting they are said to become astringent, and as such are used for *diarrhœas*, especially of children. By European practitioners they have been chiefly employed in *chronic diarrhœa*. The Br. Add. recognizes a *decoction* (*Decoctum Ispaghulae*, Br. Add., two drachms to the pint), given in doses of one-half to two fluidounces (15–60 Cc.). The dose of the powder is 50 to 150 grains (3.2 to 9.8 Gm.).

Issue Peas.—These are globular beads, of the size of a pea, made of woody substances of spongy structure, intended to be introduced into issues, abscesses, etc., for the purpose of promoting suppuration.

Jacaranda.—Several species of this genus (Fam. Bignoniaceæ) are employed in *syphilis* in Brazil and other portions of South America under the names of *caroba*, *carobinha*, etc. Peckolt (A. J. P., 1882, 134) has found in them a crystalline substance, *carobin*, besides resins and acids, such as *carobic* and *steocarobic* acids, and *curobon*, *caroborelinic* acid, and *caroba* balsam. Hesse (Ann. Chem., 252, 150) found only an aromatic resin, but no alkaloid. The value of the remedy has been asserted in the *B. M. J.*, vol. i. 1885. For further information, consult *P. J.*, 3d series, vols. v., xii., and xiv., and also A. J. P., 1882.

Jambosa Root.—This is the root of *Eugenia Jambos* (*Myrtus Jambos*, H. B. K., *Jambos vulgaris*, DC., *Eugenia jambosa*, Crantz), of the fam. Myrtaceæ, which is widely cultivated in the tropics under the name of the *rose-apple*. It has been found by A. W. Gerrard to contain an oleoresin, besides a crystalline principle, *jambosin*, $C_{10}H_{15}NO_3$. Lyons has also found in it minute quantities of an alkaloid. The decoction of the bark of the root is used as an astringent in dysentery, gonorrhœa, and leucorrhœa. (*P. J.*, March, 1884.)

Jambu Assu. *Piper Jaborandi*.—The root of *Piper Jaborandi*, Vell. (*Serronia Jaborandi*, Guill., *Ottonia Jaborandi*, Kunth) (Fam. Piperaceæ), is one of the *jaborandis* of Brazil, which is used by the natives as a sudorific, a diuretic, and a febrifuge. It is said to contain an alkaloid and a pungent oleoresin. (See *Pilocarpus*.)

Jatropha. *Jatropha macrorhiza*, Benth. *Jicama*. This is a euphorbiaceous plant which inhabits Northern Mexico and the adjoining United States. It is a mild purgative, acting excessively in overdose, and is believed by the Mexicans to be cholagogue. The dose of the fluid-extract is stated to be from one-half to two fluidrachms (1.8–7.5 Cc.).

Jeffersonia. *Jeffersonia diphylla* (L.), Pers. *Twingleaf*. (Fam. Berberidaceæ).—This herbaceous perennial is found in various parts of the Middle and Middle-Western United States. The rhizome, which, with the rootlets attached, is the part used, has a brownish-yellow color, and a bitter, acrid taste, which resides in its cortical part, the inner portion being nearly tasteless. E. S. Wayne of Cincinnati, found it to contain albumen, gum, tannic acid, starch, pectin, a fatty resin, hard resin, sugar, lignin, and a peculiar acrid principle, having acid properties and resembling polygalic acid, in which it is supposed that the virtues of the root reside. The root is said to be emetic in large doses, tonic and expectorant in smaller doses and not unlike senega, as a substitute for which it is sometimes used. (*A. J. P.*, xxvii. 1.) According to Mayer of New York, the rhizome of this plant contains a small quantity of berberine and a second white alkaloid. The pectin of Wayne he considers to be saponin. (*Ibid.*, 1863, 99.) A. W. Flexor proved the absence of berberine from the root. (*Am. Drug.*, 1884.) Gordin has since confirmed this view (1902).

Jellies.—The form of jelly is sometimes a convenient method of administering medicines, especially the fixed oils, as cod liver oil, castor oil, resinous juices, etc. The following is a formula recommended by Parrish and William C. Bakes. "Take of the fixed oil or liquid resin a *troy-ounce*; honey, syrup, each, *half a troy-ounce*; gum arabic, in powder, *two drachms*; Russian isinglass, *forty grains*; orange-flower water, *six*

fluidrachms. Dissolve the isinglass, with the aid of heat, in half a fluidounce of the orange-flower water, replacing the water as it evaporates. Triturate the other ingredients, with the remainder of the orange-flower water, into a homogeneous mass in a warmed mortar, then add the hot solution of isinglass, stir the mixture as it cools, and set it aside to gelatinize." (*A. J. P.*, 1861, 4.) Any other aromatic water may be substituted for that of the orange flower, and cinnamon water diluted with an equal measure of pure water would probably better cover the offensive taste. In reference to cod liver oil, the bitter-almond, or cherry-laurel water would be still more effectual, care, however, being taken, in this case, that the water be duly diluted, lest too large a dose of it be administered.

Juglans. *U. S. 1890.*—"The bark of the root of *Juglans cinerea* Linné (nat. ord. *Juglandaceæ*), collected in autumn." *U. S. 1890.* *Ecorce de Noyer gris*, Fr. *Graue Wallnussrinde*, G. Several products of *Juglans regia*, L., or common European walnut, are used medicinally in Europe. The hull of the fruit has been employed as a vermifuge from the times of Hippocrates, and has been recommended in *syphilis* and for old ulcers. The expressed oil of the fruit has been deemed efficacious against the *tapeworm*, and is also used as a laxative injection. The leaves, long occasionally employed for various purposes in both regular and domestic practice, have been found by Négrier of Angers, in the highest degree efficacious in *scrofula*. He gave to children a teacupful of a pretty strong infusion, or six grains (0.4 Gm.) of the aqueous extract, or an equivalent dose of a syrup prepared from the extract, two, three, or four times a day, and at the same time applied a strong decoction to the ulcers, and as a collyrium when the eyes were diseased. No injury ever resulted from a long-continued use of the remedy. It appears to act as a moderately aromatic bitter and astringent. (*A. G. M.*, 3e sér., x. 399 and xi. 41.) They are said also to have proved useful as a topical application in *malignant pustule*. (*Ibid.*, 5e sér., x. 609.)¹ The leaves of *J. nigra*, L. (*black walnut*),² and those of *J. cinerea*, probably possess the same properties.

Juglans cinerea, Willd. *Juglans cathartica*, Michaux. *Butternut*. *Oil Nut*. *White Walnut*. *U. S. 1890.*—An abundant tree of the Northern, Eastern and Western portions of the old United States, reaching into Canada. The fruit, when half grown, is sometimes made into pickles, and, when ripe, affords in its kernel a grateful article of food. The bark is used for dyeing wool a dark-brown color, though inferior for this purpose to that of the black walnut. It is said to be rubefacient when applied to the skin. The inner bark

¹ **Nucitannic Acid.**—In the walnut, between the kernel and the shell, is a thin membrane, which closely embraces the cotyledon, called the *episperm*, which consists of two layers, the inner very thin, colorless, translucent, and perfectly tasteless, the outer coarser, somewhat colored, and of a bitter, disagreeable taste. The latter, examined chemically by T. L. Philpson, was found to contain, among other principles, as gallic and ellagic acid, etc., a new variety of tannic acid, which he proposes to name *nucitannic acid* or *nucitannin*, to which the outer membrane chiefly owes its unpleasant taste. It is a glucoside, as when boiled for some hours with diluted hydrochloric acid it splits into glucose and a peculiar red acid substance, which he calls *rothic acid*, $C_{14}H_{12}O_7$, and the properties of which he has pretty thoroughly investigated. (*Chem. News*, Sept. 3, 1869, p. 116.)

² For an exhaustive chemical examination of black walnut leaves by Miss L. J. Martin, see *A. J. P.*, 1886, p. 468.

is the medicinal portion; that of the root, being considered most efficient, was directed by the U. S. P. It should be collected in May or June.

On the living tree, the inner bark, when first uncovered, is of a pure white, which immediately on exposure becomes a fine lemon color, and ultimately changes to deep brown. It has a fibrous texture, and was officially described as follows: "In flat or curved pieces, about 5 Mm. thick; the outer surface dark gray and nearly smooth, or deprived of the soft cork and deep brown; the inner surface smooth and striate; transverse fracture short, delicately checkered, whitish and brown; odor feeble; taste bitter and somewhat acrid." U. S. 1890. Its medicinal virtues are extracted by boiling water. Bigelow could detect no resin in the bark, and the presence of tannin was not evinced by the test of gelatin, though a brownish-black color was produced by ferrous sulphate. Charles O. Thiebaud found the bark to be destitute of tannic acid and of any vegetable alkaloid, but to contain bitter extractive, oily matter in large proportion, a volatilizable acid crystallizing in bright, orange-yellow crystals, and appearing to bear some analogy with chrysophanic acid, named *juglandic acid*, another acid crystallizing in tabular colorless crystals, and a volatile acid, with ashes, potassium largely, with traces of sodium, calcium, and aluminum. (A. J. P., 1872, p. 253.) Dawson found resin in very small proportion, a volatile acid, and, besides the bases discovered by Thiebaud, magnesium, combined, as were the other bases, with carbonic, hydrochloric, phosphoric, and silicic acids. Maisch has no doubt that the juglandic acid of Thiebaud is the *nucin* of A. Vogel, Jr., found in green walnut peel. (A. J. P., April, 1874, 167.) E. D. Truman (*Ibid.*, 1893, 426) made proximate analyses of the root bark and the trunk bark for comparison. In the trunk bark, instead of the crystallizable juglandic acid, he found an uncrystallizable acid and a crystalline resin. Tanret and Villiers isolated from the leaves a carbohydrate, *nucite*, $C_6H_{12}O_6 + 2H_2O$, which fuses at $218^\circ C$, is not fermentable, and does not reduce Fehling's solution. It has since been shown to be identical with *inosite*. Tanret also (*Jahresb. f. Pharm.*, 1876, 198) thinks that he has obtained an alkaloid from walnut leaves, which he proposes to call *juglandine*. The European walnut bark yielded *glycyrrhizin* abundantly to Sestini. *Juglon*, $C_{10}H_8O_3$, the characteristic constituent of *Juglans regia*, has been prepared synthetically by Bernthsen and Semper, and is now recognized as *o-oxynaphthoquinone*, $C_{10}H_6(OH)O_2$, as it can be made from dioxynaphthalene by the action of chromic acid mixture. It is in brownish-red crystalline needles having a faint odor of walnut hulls, and is sternutatory. (Ber. d. Chem. Ges., 1887, 934.)

Extractum Juglandis. U. S. 1890. *Extract of Juglans*. *Extrait d'Ecorce de Noyer gris*, Fr.; *Butternussrinden-Extrakt*, G. *Extract of Butternut*.—"*Juglans*, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then

allow the percolation to proceed, gradually adding Diluted Alcohol, until three thousand cubic centimeters [or 101 fluidounces, 212 minims] of tincture are obtained, or the *Juglans* is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." U. S. 1890.

Butternut is a mild cathartic resembling rhubarb in its action, but less certain. It was much used during our Revolutionary war as an habitual laxative, and was especially esteemed by Rush in the treatment of dysentery and hepatic congestions. It should always be given in the form of extract. Dose of the extract, from twenty to thirty grains (1.3–2.0 Gm.), or as a laxative, five to ten grains (0.32–0.65 Gm.).

Juniperus. U. S. 1880. *Juniper*. *Fructus Juniperi*, P. G. *Bacca Juniperi*. *Juniper Berries*. *Genièvre*, Baies de Genièvre, Fr. *Gemeiner Wachholder*, *Wachholderbeeren*, G. *Ginepro*, It. *Enebro*, Bayas de Enebro, Sp.

Juniperus communis, L. (Fam. Coniferae), is an erect evergreen shrub, usually small, but sometimes twelve to fifteen feet high, with numerous very close branches.

The common juniper is a native of Europe and the northern regions of Asia and North America. Northward it becomes a trailing shrub, seldom more than two or three feet high, spreading in all directions, throwing out roots from its branches, and forming beds which are often many rods in circumference. The name of *J. depressa* has been proposed for this variety. The common juniper flowers in May, but does not ripen its fruit until late in the following year. All parts of the plant contain a volatile oil, which imparts to them a peculiar flavor. The wood has a slight aromatic odor, and was formerly used for fumigation. A terebinthinate juice exudes from the tree and hardens on the bark. This has been erroneously considered as identical with the gum known commercially as *sandarach*.

The berries, as the fruit is commonly called, are occasionally brought to the Philadelphia market from New Jersey. But, though equal to the European in appearance, they are inferior in strength, and are not much used. The best come from the south of Europe, particularly from Trieste and the Italian ports. They are globular, more or less shrivelled; about as large as a pea; marked with three furrows at the summit, and at the base with tubercles from the persistent calyx, and covered with a glaucous bloom, beneath which they are of a shining blackish-purple color. They contain a brownish-yellow pulp, and three ovate, long, bony, angular seeds. They have an agreeable somewhat aromatic odor, and a sweetish, warm, bitterish, slightly terebinthinate taste. These properties, as well as their medicinal virtues, they owe chiefly to a volatile oil. (See *Oleum Juniperi*, p. 849.) The other constituents, according to Trommsdorff, are resin, sugar, gum, wax, lignin, water, and various saline substances. The proportion of these constituents varies according to the greater or less maturity of the berries. The volatile oil is most abundant in those which have attained their full growth and are still green, or in those which are on the point of ripening. In the latter Trommsdorff found 1 per cent. of the oil. In those perfectly ripe it has been partly changed into resin, and in those quite black, completely so. The berries impart their virtues to water and alcohol. They are very largely consumed in the preparation of gin.

The tops of juniper were formerly directed by the Edinburgh and Dublin Colleges. Their odor is balsamic, their taste resinous and bitterish, and they possess similar virtues with the berries.

Juniper berries are gently stimulant and diuretic, imparting to the urine the odor of violets, and producing occasionally, when largely taken, disagreeable irritation in the urinary passages. They are chiefly used as an adjuvant to more powerful diuretics in dropsical complaints. The infusion is a good preparation. It is made by macerating an ounce of the bruised berries in a pint of boiling water, the whole of which may be taken in the course of twenty-four hours. The fluidextract is an eligible preparation, but for most purposes the oil is preferable. (See *Oleum Juniperi*, p. 849.)

Juniperus Virginiana. L. *Red Cedar*. *Cèdre de Virginie*, Fr. *Virginische Ceder*, *Rothe Ceder*, G.—The tops of this plant were formerly included in the Secondary List of the U. S. Pharmacopœia. The tree is an evergreen of slow growth, seldom very large, though sometimes attaining a height of forty or fifty feet, with a stem more than a foot in diameter.

It grows in all latitudes of the United States, east of the Rocky Mountains, from Vermont to the Gulf of Mexico, but it is most abundant and vigorous in the southern section. The interior wood is of a reddish color, and highly valuable on account of its great durability. Small excrescences, which are sometimes found on the branches of the tree, are popularly used as an anthelmintic, under the name of *cedar apples*, in the dose of from ten to twenty grains (0.65–1.3 Gm.) three times a day. The tops have a pleasant odor, and a strong, bitterish, somewhat pungent taste. These properties reside chiefly in a volatile oil, and are readily imparted to alcohol. The leaves, analyzed by Wm. J. Jenks, were found to contain volatile oil, gum, tannic acid, albumen, bitter extractive, resin, chlorophyll, fixed oil, lime, and lignin. (*A. J. P.*, xiv. 235.) They bear a close resemblance to the leaves of *Juniperus Sabina*, L., from which they can be certainly distinguished only by the difference of odor. The oil of red cedar is now an article of commerce; it is used generally in perfumery, and is one of the principal constituents of the popular extract of white rose. (*A. J. P.*, 1877, 186.) It possesses, in a marked degree, the well known agreeable odor of the red cedar wood. *Cedrene camphor*, $C_{15}H_{26}O = C_{15}H_{24} + H_2O$, may be obtained by cooling the oil until coagulated, and separating the crystalline portion by expression; the expressed liquid is *cedrene*, $C_{15}H_{24}$, which, after rectification and distillation, has the sp. gr. 0.984 at 15° C. (59° F.), boiling at 237° C. (458.6° F.). Cedrene may also be prepared from the cedrene camphor by the dehydrating action of phosphoric anhydride, P_2O_5 . The resemblance of red cedar to savin is said also to extend to its medicinal properties. It is, however, much less energetic, and has not acquired the confidence of the profession. Externally applied it acts as an irritant, and an ointment, prepared by boiling the fresh leaves for a short time in twice their weight of lard with the addition of a little wax, is employed as a substitute for savin cerate in maintaining a purulent discharge from blistered surfaces. Sometimes the dried leaves in powder are mixed with six times their weight of rosin cerate, and used for a similar purpose. But neither of these preparations is as effectual as the analogous preparation of savin.

The volatile oil, which resembles oil of savin in its medicinal properties, has been used for the purpose of producing abortion, and in some cases has caused death. The symptoms have been burning in the stomach, vomiting, convulsions, coma, and a slow pulse, with evidences of gastro-intestinal inflammation after death. (See S. C. Watt, *B. M. S. J.*, vol. xl.)

Under the name of cedar are known in commerce various trees, some of which do not belong to the genus *Juniperus*. The wood of *Juniperus bermudiana*, L., is said to be largely used in making pencils. The cedar of Lebanon, *Cedrus Libani*, Barrel, and its two varieties, the African cedar, *C. atlantica*, Manetti, and the Indian cedar or deodar, *C. Deodara*, Loud., are sometimes distilled for oil, and, under the name of *libanum*, an oil obtained from *Cedrus atlantica*, Manetti, or *satin-wood*, has appeared in commerce and is said to be useful in the treatment of *blennorrhagia*, *phthisis*, *bronchitis*, and *eruptions* upon the skin, having properties very similar to those of the oil of santal. It may be given in capsules up to forty-five grains (3 Gm.) per day. In skin eruptions the 25 per cent. ointment made with vaseline has been used. Other trees known as cedars are the *white cedar*, *Cupressus thyoides*, L.; the American white cedar, *Thuja occidentalis*, Linn.; the Californian white cedar, *Libocedrus decurrens*, Torr.; the New Zealand cedar, *Libocedrus Bidwillii*, Hook. The Australian red cedar, *Cedrela Toona*, Roxb., and the West India cedar, *Cedrela odorata*, L., belong to an entirely different family, the Meliaceæ (Cedrelaceæ). The wood of the latter species is used in making cigar boxes, and, according to Schimmel, yields 3 per cent. of a volatile oil, which has a specific gravity of 0.915, boils between 265° and 270° C. (509° to 518° F.), and has an optical rotation of 5.053° in a 100 Mm. tube. It is said to be a powerful insecticide. (*P. J.*, Aug. 29, 1896, 179.)

Kairine. *Kairin*, G.—The hydrochloride of methylxytetrahydroquinoline, $C_{10}H_{13}ON.HCl + H_2O$, is the commercial kairine (kairine M). Quinoline is treated with sulphuric acid, forming *quinoline-sulphonic acid*, which, fused with caustic soda, yields *oxyquinoline*, which is then reduced with tin and hydrochloric acid, forming *tetrahydroxyquinoline*, and this, on treatment with methyl bromide, yields *methyltetrahydroxyquinoline* or kairine. *Kairine A* is the corresponding ethyl compound, and has similar properties. Kairine, as brought into commerce, is readily soluble in water and alcohol, and forms a grayish-white crystalline powder, with bitter, salty taste. Ferric chloride produces a dark brown color, which upon the addition of sulphuric acid turns purple.

Kairine belongs to the antipyretic remedies, and is without doubt capable of producing pronounced fall of temperature in fever, accompanied by copious sweating. It is, however, a cardiac depressant, which is said to act directly upon the cardiac muscles, and is very prone to produce cyanosis and collapse. The reports have been so unfavorable that, in the absence of advantage over antipyrine and antifebrine, kairine is no longer used in practical medicine. *Dose*, five to ten grains (0.32–0.65 Gm.).

Kairoline. M. or A. *Tetrahydromethylquinoline*, or *Tetrahydroethylquinoline*.—These bases differ from kairine in not containing oxygen. Their characters are similar. The sulphates are the commercial salts. For physiological action, see *Ber. d. Chem. Ges.*, xvi. 739.

Kaladana. *Br. Add. Pharbitis Nil.*—"The dried seeds of *Ipomœa hederacea*, Jacq." Closely allied to *Ipomœa hederacea* is *I. muricata*, the seeds of which are largely imported into Bombay, from Persia, under the name of *tukm-inil*. The juice of this plant is employed to destroy bedbugs, and the seeds are said to be identical in their medicinal properties with those of the official plant. Kaladana seeds are in the form of the segment of a sphere, black, somewhat hairy, weighing from one-half drachm to nearly one drachm. From them is prepared *pharbitisin*, *kaladana resin* (*Kaladana Resina*, *Br. Add.*), by digesting the seed with twice its weight of alcohol until exhaustion, and precipitating with distilled water. (For detail see *Br. Add.*) Kaladana resin occurs "in brownish opaque fragments, translucent at the edges, brittle, breaking with a resinous fracture, readily reduced to a gray powder; sweetish, and acrid to the throat; somewhat disagreeable in odor especially when warmed; easily soluble in alcohol (90 per cent.), practically insoluble in benzol, ether, chloroform, or carbon bisulphide. It melts at about 320° F. (160° C.)." *Br. Add.*

Kaladana seeds are actively purgative. In small doses they produce little or no irritation, but in large doses are capable of acting as a violent drastic cathartic. The *Br. Add.* recognizes a compound powder of kaladana (*Pulvis Kaladana Compositus*, *Br. Add.*), composed of five parts of kaladana, nine parts of potassium tartrate and one part of ginger, which is an imitation of the compound powder of jalap, and is used for similar purposes, in the dose of twenty to sixty grains (1.2-3.9 Gm.). *Tincture of kaladana* (*Tinctura Kaladana*, *Br. Add.*, four ounces in one pint) is given in the dose of one-half to one fluidrachm (1.8-3.75 Cc.). Much the best preparation is the resin, dose, two to eight grains (0.13-0.5 Gm.) administered in pill or capsule, combined with extract of belladonna or an aromatic.

Kalagua.—A study of this South American plant, which has been put upon the market as a specific for tuberculosis, made upon the lower animals by D. H. Bergey, shows that it has no specific influence upon the tubercle bacillus.

Kalmia. *Kalmia latifolia*, L. Laurel. Mountain Laurel. Broad-leaved Laurel. Calico-bush. Spoonwood. *Kalmie*, Fr., G.—This well-known ericaceous evergreen is found from New Brunswick to Florida and from Ohio to Louisiana, being especially abundant on the sides of hills and mountains. It is from three to ten feet in height. The leaves, which are supposed to be possessed of poisonous, narcotic properties, have been found by Charles Bullock to contain gum, tannic acid, resin, chlorophyll, fatty matter, a substance resembling mannite, an acrid principle, wax, extractive, albumen, yellow coloring matter, lignin, and salts of potassium, calcium, and iron. (*A. J. P.*, xx. 264.) George W. Kennedy detected the glucoside arbutin in them. (*Ibid.*, xlvii. 5.) Although chemists have failed to find the toxic principle in this plant, the leaves are popularly believed to be poisonous to sheep and other small animals, but are said to be eaten with impunity by deer, goats, and grouse. It is also affirmed that severe and fatal poisoning has been produced by eating grouse that have fed upon these leaves. (See 16th ed. *U. S. D.*) Scientific proof of the poisonous properties of the laurel still seems to be lacking. The leaves have been used internally in *diarrhœa* and in *syphilis*, and externally in skin diseases. (See 16th ed. *U. S. D.*)

It is probable that other species of *Kalmia*, as *K. angustifolia*, L., or sheep-laurel, and *K. glauca*, Ait., or swamp-laurel, have properties identical with those of *K. latifolia*. A decoction of the leaves of *K. angustifolia* is used by the negroes as a wash for ulcerations between the toes.

Kamala. *U. S.* 1890. *Kamala. Glandulæ Rottleræ.*—The *U. S. Pharmacopœia*, under the name of *Rottlera*, *U. S.* 1870, *Kameela*, formerly recognized the glands and hairs from the capsules of *Mallotus philippinensis* (Lamarck), Muell. Arg. (*Rottlera tinctoria*, Roxburgh). This tree grows in Abyssinia, Southern Arabia, Hindostan, the East India islands, China, and Australia, reaching a height of from fifteen to twenty feet, and yielding a roundish, three-valved, three-celled capsule about the size of a small cherry, thickly covered with a red powder, which is collected in Hindostan by rolling the berries about in large baskets until the freed powder sifts through the open wicker-work.

Kamala, as brought to our market, is a light, finely granular, very mobile powder, of a brownish-red or madder color, with little odor or taste, but producing a slight sense of acrimony in the mouth, and feeling gritty under the teeth. (When the grittiness is excessive, the drug has probably been adulterated with earthy matters.) It is inflammable, and flashes almost like gunpowder when dropped into the flame of a candle. It is insoluble in cold and but very slightly soluble in boiling water; but alkaline solutions, alcohol, and ether dissolve a large proportion of it, forming a deep red solution, from which water precipitates resinous matter, "imparting a deep red color to alkaline liquids, alcohol, ether, or chloroform, and a pale yellow tinge to boiling water." *U. S.* 1890. Under the microscope it consists of garnet-red, semi-transparent, roundish, glandular granules, from $\frac{1}{100}$ to $\frac{1}{50}$ of an inch in diameter, and containing numerous red, club-shaped vesicles, more or less mixed with minute stellate hairs, and the remains of stalks and leaves, the latter of which are easily removed by careful sifting. It has been examined chemically by Thomas Anderson of Glasgow, and by G. Leube, in Germany. As given by the former, the constituents are, in 100 parts, 78.19 of resinous coloring matter, 7.34 of albumin, 7.14 of cellulose, etc., a trace of volatile oil and volatile coloring matters, 3.84 of ashes, and 3.49 of water. The amount of earthy impurities, chiefly sand, in commercial kamala, varies greatly, sometimes amounting to fifty or even sixty per cent. It can readily be estimated by heating the drug to redness and weighing the residue. The *U. S. P.* permitted the presence of "not more than 8 per cent. of ash." Any specimen of kamala containing more than the official percentage of impurity should be rejected. Of the resinous coloring substances, Anderson obtained one in a pure state by allowing a concentrated ethereal solution to stand for two days, draining and pressing in bibulous paper the resulting mass of granular crystals, and purifying them from adhering resin by repeated solution in ether and recrystallization. To this substance he gave the name of *rottlerin*. It is in the form of minute crystalline plates, of a yellow color and a satin-like lustre, insoluble in water, sparingly soluble in cold but more so in boiling alcohol, and readily dissolved by ether, and by alkaline solutions, which assume a dark red color. *Rottlerin* melts when heated moderately, and at a higher heat is decomposed, giving off pungent vapors. Its

formula, according to Anderson, is $C_{11}H_{10}O_8$. A and W. Perkin (*Ber. d. Chem. Ges.*, 19, 3109) and Jawein (*Ibid.*, 20, 182) both stated that rottlerin can be extracted from kamala by the action of carbon disulphide. Jawein gave its fusing point as $200^{\circ} C.$ ($392^{\circ} F.$), and said that it was easily soluble in hot alcohol and acetic acid. In a later communication, A. G. Perkin (*P. J.*, 1893, 159, 236), stated that when he extracted it with ether, kamala yielded a dark brownish resinous product from which six distinct substances can be isolated. Rottlerin, iso-rottlerin, a wax, and two resins, one of high and one of low melting point, form the principal constituents. There is also present a trace of a yellow crystalline coloring matter melting at from 192° – $193^{\circ} C.$ (377.6° – $379.4^{\circ} F.$). The formula $C_{11}H_{10}O_8$ for rottlerin is confirmed. Perkin also found in kamala a small quantity of a sugar soluble in water. Potassium permanganate oxidizes it to oxalic and benzoic acids; nitric acid of 1.5 sp. gr., on the other hand, oxidizes it to oxalic acid, ortho- and para-nitrocinnamic acids, and para-nitrobenzoic acid. The ashes were in the extraordinary proportion of 25.85 per cent., and of the ashes 83.8 per cent. consisted of insoluble silica. Silica probably enters essentially into the constitution of the minute granules, and its presence accounts for their grittiness under the teeth. The active constituent is supposed to be the resin.

Kamala is actively or even violently purgative in full doses, occasionally causing nausea, but seldom vomiting. Although long used in India against the *tape worm*, the value of kamala as a tæniifuge was first made generally known by C. Mackinnon (*Ind. Ann. Med. Sci.*, 1854). It is given, without previous preparation of the patient, in the dose of from one to three drachms (3.9–11.6 Gm.), suspended in water, mucilage, or syrup. In the latter dose it sometimes acts violently. The worm is usually expelled dead at the third or fourth stool. If the first dose fails to operate on the bowels, it may be repeated in four hours, or followed by a dose of castor oil. The tincture (four ounces to eight fluidounces of diluted alcohol) is also said to be efficient in doses of from one to four fluidrachms (3.75–15 Cc.). As an external remedy, kamala is used by the people of India in various affections of the skin, particularly *scabies*. William Moore of Dublin, has employed it successfully in *herpetic ringworm*. (*Dublin Hosp. Gaz.*, Nov. 15, 1857.)

Kandol. *Canadol.*—This is a light fraction of petroleum of great volatility, which is said to afford a very cheap and efficient means of rapidly freezing the skin and subdermal tissues.

Kava Rhizome. *Kava Rhizoma.*—"The decorated, dried, and divided rhizome, without the roots, of *Piper Methysticum*, Forster." *Br. Add.* *Ava*, or *kava*, is the native name of a beverage formerly prepared in the Sandwich Islands, by the aborigines, from the root of the *Piper Methysticum*, Forst. (*Macropiper Methysticum*, Miq., *Methysticum esculentum*, Raf.). The intoxication produced by this drug is wholly unlike that caused by alcohol, being of a silent and drowsy character, accompanied by incoherent dreams, with great loss of muscular power, which is probably due to the action of kava resin upon the spinal cord.

The rhizome of the kava is large, fibrous, and spongy. In commerce "it occurs in whitish or light brownish-gray irregularly cuboid or roughly wedge-shaped fragments, from which the gray periderm has been sliced off; from half an inch to

two inches (one and a quarter to five centimetres) thick. Most of the fragments exhibit, when cut, a central portion of a close, even texture, surrounded by a distinct ring of narrow radiating vascular bundles, separated by relatively broad paler medullary rays. The rhizome has a starchy fracture, a slight somewhat pleasant odor, and, when masticated, a piperaceous, faintly bitter, and slightly saponaceous taste. Pieces of a coarsely porous or very woody character should be excluded." *Br. Add.*

Gobley isolated from kava root a crystalline principle (analogous to piperin), *methysticin*, or *kavahin*, which is without odor and taste, and is probably inert. (*J. P. C.*, Jan. 1860.) It possesses the formula $C_{16}H_{18}O_8$, and when purified forms silky, lustrous needles melting at 138° to $139^{\circ} C.$ (280.4° to $282.2^{\circ} F.$). *Kavahin* differs from piperin and cubebin in being colored red by hydrochloric acid, the red color fading on exposure to air into a bright yellow, and in being colored by strong sulphuric acid a purplish violet, which passes into green. In 1844 Morson discovered an active principle, *kawine*. This is a greenish-yellow, strongly aromatic and acid resin. It was again studied by Cuzaut in 1860, and by Lewin in 1886. This latter investigator separates it into two resins, of which the β -resin is greasy and of a reddish-brown color, appearing in mass almost black. This is less active than the α -resin, which is yellowish brown, has the characteristic odor of the drug, is freely soluble in alcohol, and placed upon the tongue produces a burning sensation followed by local anæsthesia. (*A. J. P.*, 1886, 450.) A volatile oil has also been found in the root. (*J. P. C.*, March, 1862.) Lavielle (*L'Union Pharm.*, Jan. 1889) claims to have obtained an alkaloid, *kavaine*. (See also *Proc. A. Ph. A.*, 1897, 564.)

The physiological action of kava root and its resin has been especially investigated by L. Lewin (*Piper Methysticum*, Berlin, 1886), and David Cerna (*T. G.*, 1891). The phenomena which follow the hypodermic injection of the fluidextract of kava or of a solution of its resin are, anæsthesia at the point of injection, followed after absorption by general paralysis, due to a direct paralysis of the motor side of the spinal cord, the motor nerves and the muscles remaining intact. The local anæsthesia is due to a paralysis of the sensory nerve filaments, and when the resin is brought in contact with the mucous membranes there is a burning pain, followed in time by a complete loss of sensibility, which is remarkably permanent, since Lewin found that from six to seven minims of a solution of kava injected beneath the skin produced a complete loss of sensibility in the surrounding area, which did not pass away for eight days. (*D. M. Ztg.*, Feb. 1886.) The action of the drug upon the circulation is subordinate to its nervous influence, but according to the experiments of Cerna it does stimulate the heart, although it decreases the number of pulsations by stimulating the inhibitory nerve centres. The same investigator found that at first it stimulates, afterwards depresses, and finally paralyzes the respiration, by an action upon the centres. The insolubility and irritant action of kava resin prevent its use as a practical local anæsthetic.

As long ago as 1857 kava root was employed in the treatment of *gonorrhœa*, and there is much testimony to its value both in the acute and the chronic form of the disease, as well as in *vaginitis*, *leucorrhœa*, *nocturnal incontinence*, and similar conditions of the genito-urinary tract.

Of the *liquid extract of kava* (*Extractum Kava Liquidum*, Br. Add.), one imperial pint represents twenty avoirdupois ounces of the rhizome; it is given in *doses* of from thirty to sixty minims (1.8-3.75 Cc.), and is probably the best form for the administration of the drug.

Kephir. *Kefir*.—This is milk which has undergone a peculiar fermentation caused by certain fungus masses, which have been long known by the Tartars as *Kephir seed*, or as the *Millet of the Prophet*. They are white, irregularly roundish bodies, of about the size of a walnut, with a very rough furrowed surface, a tough gelatinous, or, when dried, cartilaginous consistency. They have been found by morphologists (C. D. Spivak, *N. Y. M. J.*, 1896) to be composed of three different organisms. 1. *Saccharomyces cerevisiæ* (Meyen), or the yeast fungus; 2. *Bacillus acidilactici* (Pasteur); and 3. *Dispora caucasica*, Kern, or *Bacillus kephir* (Sorokin), a rod-shaped bacterium. For an analysis of kephir, see König's *Nahrungs- und Genussmittel*, 3te Aufl., Bd. i. 420.

For the methods used by the Tartars in preparing kephir, see the previous editions of the *U. S. D.*, also the paper by Spivak. The method of Dmitrieff, which may be practised by any one having the kephir grains, is described in the *N. Y. M. J.*, Jan. 1896. According to Spivak, the changes in milk during kephirization are as follows: 1. Fat, salts, and water remain unchanged. 2. The quantity of lactose is gradually lessened from 30-50 per mille to 16-30 per mille in the second-day kephir, and to 12-20 per mille in the third-day kephir. 3. Lactic acid is increased from 3.5-8.6 per mille in second-day kephir to 6.3-9.0 in third-day kephir. 4. Alcohol is produced from 5.3-8.0 per mille in second-day kephir to 6.0-10.0 in third-day kephir. 5. Carbon dioxide is generated in quantities approximating 10 per cent. 6. A part of the casein—namely, about 10 per cent.—is transformed into acid albumin and peptone, 10 per cent. into hemialbumose, and the rest loses its lime, and therefore becomes digestible.

Kephir may be employed for the same purposes as are koumys and matzoon. It yields its constituents readily to assimilation, and is somewhat laxative and distinctly diuretic. It may be employed in various forms of *dyspepsia*, whether organic or functional, in *anæmia* and *chlorosis*, in *rachitis*, *chronic rheumatism*, *phthisis*, and other conditions of impaired nutrition.

Keratin.—The outer skin surface, the material of horns, hoofs, tortoise shell, the finger nails, all show a similar chemical composition, the empirical formula of which is said to be $C_{41}H_{71}N_{12}SO_{14}$. The percentage of sulphur varies, however, considerably. Keratin is prepared by Unna by steeping parings of horn in a digestive liquid composed of pepsin, 1, hydrochloric acid, 1, and water, 11, as long as the shavings yield anything to the solvent. The residue is then dissolved in ammonia by maceration lasting several weeks, after which the solution is evaporated.

Gissmann boils the quills of birds' feathers in glacial acetic acid for from twenty-four to thirty-six hours in a retort furnished with a return condenser. A thick yellow-brown liquid is thus obtained, which is filtered through glass wool, evaporated on a water bath to the consistence of an extract, and afterwards dried. Dieterich employs Gissmann's process, but before the treatment with acetic acid he subjects the feathers to ten hours'

digestion in water and then to eight days' maceration in a mixture of equal weights of ether and alcohol, to eliminate fatty matters and cholesterol.

Keratin obtained by one of the foregoing processes is dissolved with the aid of a gentle heat either in acetic acid or ammonia, and the solution is allowed to clear by standing. Fischer recommends the employment of seven parts of keratin with either one hundred parts of acetic acid, or a mixture of equal parts of ammonia and diluted alcohol. Keratin is insoluble in water, alcohol, ether, and diluted acetic acid, or acidulated pepsin solution. Diluted sulphuric acid on boiling changes it into leucin, tyrosin, and other products. It is soluble in concentrated acetic acid, alkalies, and ammonia.

Keratin has been employed for the purpose of coating pills, so as to enable them to pass through the acid juices of the stomach and be dissolved in the alkaline intestinal fluids. It is proposed to use these coatings for four classes of medicine: 1. Medicines that can by prolonged contact cause irritation to the mucous membrane of the stomach: arsenic, salicylic acid, creosote, chrysarobin, quinine compounds, copaiba, cubeb, ferruginous preparations and especially ferric chlorides, opium, mercurial preparations and especially mercuric iodide and chloride, phosphorus, and all the tanifuge preparations. 2. Medicines that can injure the digestion by giving insoluble precipitates with pepsin and peptones: tannin, alum, lead acetate, preparations of bismuth, silver nitrate, corrosive sublimate, etc. 3. Medicines that are rendered inactive or decomposed by the gastric juice: alkali, bile, soap, calcium sulphide, iron sulphide, pancreatin, etc. 4. Medicines which should arrive in the intestines as concentrated as possible: kousoo, santonin, extract of male fern, alkali. For the preparation of a solution of keratin suitable for the coating of pills several formulas have been proposed, in all of which either acetic acid or ammonia is used as a solvent. The acetic solution might be used for coating pills containing salts of mercury, gold, or iron, arsenic, creosote, salicylic acid, tannin, alum, etc. On the other hand, recourse might be had to an ammoniacal solution for pills containing pancreatin, trypsin, bile, alkalies, iron sulphide, etc. If the pill mass should contain water, the pills would shrink and fissures would be produced in the keratin coating. It is, therefore, recommended to use in the making of these pills a mixture of yellow wax, one part, and suet or cacao butter ten parts. It is also necessary to avoid the use of vegetable powders and to employ in their place kaolin or charcoal powder.

When the pills are finished they should be dipped in cacao butter, rolled in charcoal powder, and then keratinized. For this purpose the pills, placed in a porcelain capsule, are sprinkled with a suitable quantity of keratin solution and then shaken together until the evaporation of the solvent takes place. This moistening and drying require to be repeated several times (as many as ten) before the layer of keratin is sufficiently thick. The process employed for coating pills with gelatin, which consists in dipping into the solution the pill fixed on the point of a needle, is not suitable here, for it leaves a hole through the keratin coating that can never be completely closed.

In order to insure that the keratin used is insoluble in the stomach, Unna recommends that a

preliminary experiment should be made with calcium sulphide pills coated with it. If in the course of some hours after such pills are taken eructations of hydrogen sulphide are observed, it would indicate that the pills have been dissolved in the stomach. When the keratin is of good quality nothing of the kind should occur. Finally, the pills when placed in water should not liquefy or crack. (Bourquelot.)

Kinkeliba.—This is the leaf of a plant growing in Western Africa which is affirmed to be of great value in the treatment of bilious hæmaturic malarial fevers. The plant has been attributed to various species of the genus *Combretum*, but probably is the product of the *C. micranthum*. Heckel and Schlagdenhauffen found in the leaves nothing more active than tannin. (See Perrot and Lefevre, *Travaux du Laboratoire de Mat. Méd.*, page 67.)

Kola Nuts. *Cola acuminata* (Beauv.), Schott. (*Sterculia acuminata*, Beauv., *Bichea solitaria*, Stokes.) *Semen (Nuces) Colæ. Noix de Cola, Noix de Gourou, Café du Soudan*, Fr. *Kolanuss*, G. These are yielded by the large African tree extensively cultivated in various portions of the tropical world for its seeds, which, under their Guinea name, or the Soudan name of *guru nuts*, are extensively employed as a caffeinic stimulant in Africa and other portions of the world. Six hundred tons of them are said to be sent yearly to Brazil for the use of the negroes, who, it is affirmed, also employ the seeds of *S. Chica*, A. St.-Hil., and *S. striata*, A. St.-Hil. (*S. lasiantha*, Mart.). Three varieties of kola nuts are said to be the product of *C. acuminata*. The most valuable, the kola of Sakhala, is the largest, and is of a white color. The kola of Kassi, of Siarra, and of Touté, is of medium size, red or white. The kola of Maninian is small and red. According to Binger, in the Congo the white kola of Anno is yielded by a distinct species, *S. macrocarpa*. Of this white kola there are two varieties, one whitish, resembling the kola of Sakhala but smaller; the other more or less rose-colored and larger. The kola nut itself is irregular in form, reddish gray in color, from three-quarters of an inch to an inch and a quarter in length, flattened and rounded upon one surface, irregularly scooped out or infolded upon the other surface, the nut being apparently a cotyledon, marked above with another cotyledon which it has embraced. Daniell (*P. J.*, 1865) was the first to show that kola nuts contained caffeine. Subsequently an elaborate analysis yielded to Atfield 2½ per cent. of caffeine from the nut. Schuchardt summarizes the results of his chemical analyses as follows: 1, Martinique nuts contained 1.06 per cent. caffeine; 2, Ceylon, 1.39 per cent.; 3, Gaboon, 1.47 per cent.; 4, Tropical West Africa coast, Sierra Leone, 1.69 per cent.; 5, Tropical West Africa, interior, 1.61 per cent. The chemical studies of Parke, Davis & Co. show that as found in American commerce these nuts contain from 0.72 to 2.02 per cent. of caffeine. Heckel and Schlagdenhauffen (*A. J. P.*, 1884) give theobromine 0.023 per cent., caffeine 2.35 per cent., tannin 1.62 per cent., as the result of their analyses. The researches of Knebel (*A. J. P.*, 1892, 1901), confirmed by Hilger (*Ibid.*, 568), show that fresh kola nuts probably contain no caffeine, but a glucoside, *kolanin*, which yields by its decomposition caffeine, glucose, and *kola-red* ($C_{14}H_{13}(OH)_5$). The glucoside is decomposed by a ferment present in the nuts, and therefore

readily yields the caffeine as a decomposition product. Schweitzer (1895) confirmed the results of Knebel and Hilger, and proposed for *kolanin* the formula $C_{40}H_{56}N_4O_{21}$. Knox and Prescott (*Proc. A. Ph. A.*, 1896, 136), after an investigation, assert that the kola ferment does not assist in the liberation of caffeine, but attribute the presence of caffeine to the action of heat and moisture; they also give the name of *kolatannin* or *kolatannic acid* to the tannin of kola nuts, and propose a method of assay. (*Proc. A. Ph. A.*, 1897, 131.) For Carle's method of assay, see *P. J.*, 1896, 289.

It has been asserted for kola nuts that they increase the power of enduring fatigue without food, and a dry powder or cake of kola nuts, deprived of their oil, is said to be used by the European Alpine clubs. Physiological studies have been made by Loginoff (*In. Dis.*, St. Petersburg, 1891), Davyoff (*In. Dis.*, St. Petersburg, 1891), and Kotlar (*Vrach*, 1891), which on the whole agree in showing the similarity of the action of the drug with that of others of its class. The question whether the action of kola is simply that of caffeine has been much debated, especially owing to the strenuous efforts of a drug firm to introduce kola as a popular stimulant of peculiar power. Several French observers, especially Marie, have found that kola-red is a powerful muscle stimulant, even exceeding caffeine. The very elaborate studies, however, of A. Mosso of Turin (*A. I. B.*, xix.), seem to us decisively to establish the correctness of his conclusion,—namely, that kola-red is, at least so far as the muscles are concerned, an entirely inert substance, and that the action which kola undoubtedly has upon the muscular contraction is due to the caffeine which it contains. Kola is evidently about equivalent to guarana, tea, coffee, etc., and may be substituted for them. In dose of one hundred and fifty grains (9.8 Gm.) a day, A. Hudson (*T. G.*, ii.) has found the nuts to act decisively in cardiac weakness.

The so-called *male kola* is essentially distinct from kola, being the product of a small tree, *Garcinia Kola*, and containing no caffeine. The seed is oblong, about one and a half to three inches long and from three-quarters to one inch broad; it is trigonal in section, with a readily removable thin testa of a reddish-yellow to dark brown color, covered by markings which resemble those on the seed coat of the nutmeg. In the section the microscope reveals a number of resinous masses surrounded by cells rich in starch.

The seeds of *Lucuma mammosa* (L.), Juss., (Fam. Sapotacæ), sometimes mixed with kola nuts, are recognized at once by their strong odor of prussic acid. Heckel and Schlagdenhauffen have observed the seeds of *Heritiera littoralis* mixed with kola nuts. These *false kola nuts* contain no caffeine, and are nearly orbicular and flattened in shape, one of the fleshy, white cotyledons being only half the size of the other. (*A. J. P.*, 1887, 446.)

Kosam Seeds.—The seeds of the *Brucea sumatrana*, indigenous in China and Southern Asia. Schlagdenhauffen found in them saponin, and Physalis and Bertrand a glucoside, *kosamin*. They are asserted to be useful in *menorrhagia*, also in *dysentery* and *diarrhœa*. (*P. J.*, lxi. p. 463.)

Kossala.—An Abyssinian remedy against *tape worm*. (*Proc. A. Ph. A.*, xxvi.) It is said, however, to produce gastric irritation.

Koumys. *Kumys*.—This is a liquor originally prepared by the Tartars from the milk of mares, but recently imitated with cow's milk to a great extent. It is said to be prepared in Tartary by putting the mare's milk in tall vessels while warm, adding koumys, one part for every ten of milk, stirring thoroughly every few minutes, and in three or four hours taking out and bottling in champagne bottles. (*J. P. C.*, 1875, 59.) For an account of the method employed in Russia, see *A. J. P.*, 1875, 261. The milk of the mares of the Steppes is stated to resemble that of women, being much richer than cow's milk in sugar and poorer in casein. For analyses, see *J. P. C.*, 1875, 62. The true koumys does not keep long, and therefore must be drunk at the place of production. For particulars as to the varieties of it, etc., see *J. P. C.*, Janv. 1875; also Truckenmiller, *A. J. P.*, 1880, 292. L. Wolff (*A. J. P.*, 1880, 291) has furnished, probably, the best formula for koumys: "Grape sugar, half an ounce. Dissolve it in four ounces of water. Dissolve twenty grains of Fleischmann's compressed yeast, or well-washed and pressed out brewer's yeast, in two ounces of milk. Mix the two solutions in a quart champagne bottle, which is to be filled with good cow's milk to within two inches of the top. Cork well, secure the cork with wire, and place in a cellar or ice chest, where a temperature of 10° C. (50° F.) or less can be maintained, and agitate three times a day. In three or four days the koumys is ready for use, and should not be kept longer than four or five days; it should be drawn only with a champagne tap." A beer bottle with patent stopper may be substituted for the champagne bottle.

The composition of true koumys, according to Stalberg, is given below; other analyses may be found in the *J. P. C.*, 1875, 62. *Koumys of June*. In 100 parts, alcohol 1.65, fat 2.05, sugar of milk 2.20, lactic acid 1.15, casein 1.12, salts 0.28, carbonic acid 0.75. *Koumys of September*. Carbonic acid 1.86, alcohol 3.23, fat 1.05, lactic acid 2.92, casein and salts 1.21. Stalberg gives the following as the result of an analysis of Swiss koumys, made from cow's skimmed milk to which sugar had been added. Alcohol 3.622, lactic acid 0.256, sugar 2.376, albumin 2.099, butter 2.008, mineral salts 0.574, carbonic acid 1.997. Warnikiewicz found in koumys from cow's milk 6.32 per cent. of solid material, casein 3.08, butter 0.22, milk sugar 1.77, salts 0.33, lactic acid 0.62, alcohol 1.23 parts per hundred. (See also König's *Nahrungs- und Genussmittel*, 416-419.)

These fermented milks vary in composition with the milk they are prepared from. In the following analyses, the first three columns are taken from *A. J. P.*, 1887; the matzoon analysis is by Uffelmann.

	Cow's milk.	Koumys.	Kephir.	Matzoon.
Albumin	48	11.2	38	31.2
Butter	38	20.5	20	16.0
Sugar of milk	41	22.0	20	16.2
Lactic acid	..	11.5	9	8.3
Alcohol	..	16.5	8	2.1
Water and salts	873	913.3	906	926.2

Gordon Sharp (*P. J.*, 1892, 512) stated that the composition of koumys is complex, and that the decomposition which its proteids undergo is closely allied to putrefaction.

The taste of koumys is sweet but acidulous and peculiar. In small quantities it is said to increase the appetite, in large quantities to take the place of solid food, each quart of it containing, according to Victor Jagielsky, four ounces of

solid food. (*N. R.*, i. 1.) In warm weather it is said to act as a diaphoretic, in cold weather as a diuretic. It is used especially in chronic constitutional diseases attended by emaciation, such as pulmonary *phthisis*, in chronic *abdominal catarrhs*, and in *albuminuria*. Hourowicz states that in Russia "the cure" requires from twelve to fifteen pounds of milk daily (two mares), and that the koumys is taken in doses of from a teacupful to a tumblerful every half-hour or hour early in the morning. *Giaourdi* is a fermented milk prepared in Greece from sheep and goats' milk with enzyme obtained from fermented figs.

Kryofine. *Methowacet-p-phenetidin*. *Methylglycollic Phenetidin*. $C_6H_4 \begin{cases} OC_2H_5 \\ NH.COCH_2OCH_3 \end{cases}$

This phenetidin derivative or condensation product is made by heating paraphenetidin and methylacetic acid together; the acid replaces the acetic acid in the phenetidin derivative and is thus closely allied to acetphenetidin or phenacetin. Kryofine crystallizes from aqueous solutions in needles, with a melting point of from 98°-99° C. (208.4°-210.2° F.). These crystals are white, and in moderate doses tasteless. In doses exceeding fifteen grains (1.0 Gm.), they cause, after a few moments, the sensation of chewing willow bark. It is soluble in boiling water 1 in 52, in cold water 1 in 600. It is soluble also in alcohol, ether, chloroform, and the oils in excess. The physiological action of kryofine has not been worked out, but it has been shown that the fatal dose for mice is three grains, and for a medium-sized dog two hundred and one grains, death occurring by general paralysis and extreme slowing of respiration and pulse. Seventy-five grains (5 Gm.) given to man have produced no more serious effect than cyanosis with some lessened frequency of respiration. Kryofine can be detected in the urine from fifteen to twenty minutes after taking, disappearing in from six to eight hours. (Ebstein.) In doses of from two and one-half to twenty-five grains it has been strongly commended by Ebstein, Eichhorst, Haas, Morrison, and other clinicians as an analgesic for *pains of purely nervous origin* and antipyretic in various *fevers*, and less dangerous, though acting more slowly, than other allied drugs.

The range of action of kryofine appears to be that of antipyrine. The assertion that it is less dangerous than that drug seems hardly to be sustained by the facts; depression and cyanosis have been produced by it in various cases. The usual dose is eight grains (0.5 Gm.), which may be repeated three or four times daily. In robust subjects the dose may be increased to twenty grains (1.3 Gm.), and sixty grains (3.9 Gm.) are said to have been given in the twenty-four hours with no injurious manifestations. In the feeble, great caution is necessary in its employment.

Kryogenin. *Meta-benzamino-carbamide*. $C_6H_4(CO.NH_2)(NH.NH.CO.NH_2)$.—This is a colorless, odorless, slightly bitter powder, soluble in forty parts of water. It is asserted by Lumiere (*Ph. Post*, 1903, 7) to be an antipyretic of value, especially used in *tuberculosis*, producing, it is said, a rapid fall of temperature without unpleasant symptoms. Dose, fifteen to twenty-three grains (1.0-1.5 Gm.) in capsules.

Ksopo. *Kissoumpo*. *Kisoumpa*. *Psokay*. *Tangin de Menabe*.—The ordeal poison of the Sakalaves of Madagascar (the fruit of the *Menabea venenata* (Fam. Asclepiadaceae), H. Baillon). When given to the lower animals it produces quickly a very

persistent vomiting, with rapid, irregular heart action, ending in cardiac death, consciousness being preserved to the end. (See E. Perrot, *C. R. A. S.*, 1902, 134.)

Labdanum. *Labdanum*.—A resinous substance, obtained from various species of *Cistus* (Fam. *Cistaceæ*), especially *C. creticus*, L., *C. ladaniferus*, L., *C. cyprinus*, Lam., and *C. laurifolius*, L. small evergreen shrubs, inhabiting the islands of the Grecian Archipelago, and the different countries bordering on the Mediterranean. Upon the leaves and branches of these shrubs a juice exudes, which is collected by means of an instrument resembling a rake, with leather thongs instead of teeth, which is drawn over the plant. The juice adheres to the pieces of leather, and is afterwards separated. It is said that labdanum was formerly collected by combing the beards of goats which had been browsing upon the leaves of the *cistus*, and Landerer states that it is still gathered in Cyprus from sheep and goats whose fleeces become loaded with it while they are pasturing. (See *P. J.*, xi. 6; xv. 301; xvi. 383, 779.) It comes chiefly from the Grecian Islands. Two varieties exist in commerce. The purest labdanum is in masses of various sizes, sometimes weighing several pounds, enclosed in bladders, dark red, almost black externally, grayish internally when first broken, of the consistence of a plaster, softening in the hand and becoming adhesive, of an agreeable balsamic odor like that of amber, and of a bitter, balsamic, somewhat acrid taste. It is very inflammable, burning with a clear flame. On exposure it becomes dry, porous, and brittle. Little of this variety is found in the markets. Common labdanum is in contorted or spiral pieces, light, porous, blackish gray, hard and brittle, not softening between the fingers, similar in odor and taste to the preceding variety, but less inflammable, and mixed with sand and other earthy matters, which are obvious to the sight. A specimen exhibited at the International Exhibition of 1862, at London, was in flat-tish pieces, an inch or more thick, with remains of leaves on one side, of a very dark greenish-brown color, and a granular somewhat shining fracture. Guibourt found in 100 parts of the labdanum in masses, 86 parts of resin with a little volatile oil, 7 of wax, 1 of aqueous extract, and 6 of earthy substances and hair. In the contorted variety, Pelletier found 20 per cent. of resin, 3.6 of gum with calcium malate, 0.6 of malic acid, 1.9 of wax, 1.9 of volatile oil including loss, and 72 of a ferruginous sand. Schimmel & Co. (*Schim. Rep.*, April, 1893) state that they obtained from labdanum resin 0.91 per cent. of a golden-colored essential oil having the penetrating odor of ambergris. Its sp. gr. is 1.011 at 15°C. (59°F.). Labdanum is a stimulant expectorant, formerly given in catarrh and dysentery. At present it is employed only in plasters.

Lac. *Lacca*. *Resina (Gummi) Lacca*. *Laque*, *Gomme lacque*, Fr. *Lack*, *Gummilack*, G.—A resinous substance obtained from several trees growing in the East Indies, particularly from *Croton laccifera*, L. (Fam. *Euphorbiaceæ*), a form referable to *C. aromaticus*, L., two species of *Ficus*, *F. religiosa*, L., and *F. indica*, L. (Fam. *Artocarpaceæ*), and, according to Valentine Ball, *Schleichera trijuga*, Willd. (Fam. *Sapindaceæ*), *Butea frondosa*, Roxb., of the fam. *Leguminosæ*, and *Zizyphus jujuba*, Lam. (Fam. *Rhamnaceæ*). Stillman states that *Acacia Greggii*, A. Gray (Fam. *Leguminosæ*), and *Covillea tridentata*

(DC.), Vail. (*Larrea mexicana*, Moric.) (*Zygophyllaceæ*), plants growing in Arizona, Colorado, and the Western territories, furnish both *shellac* and *lac dye*. (*A. J. P.*, 1880, 409.) Lac is found in the form of a crust, surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect belonging to the genus *Coccus*, and denominated *C. lacca*. By some it is thought to be an exudation from the bodies of the insects themselves, which collect in great numbers upon the twigs, and are embedded in the concreted juice, through which the young insects eat a passage and escape. Several varieties are known in commerce. The most common are *stick-lac*, *seed-lac*, and *shellac*.

Stick-lac is the resin as taken from the tree, still encrusting the small twigs around which it originally concreted. It is of a deep reddish-brown color, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle, and when broken it exhibits many oblong cells, often containing the dead insect. When chewed it colors the saliva beautifully red, and when burnt, diffuses a strong, agreeable odor. It is in great measure soluble in alcohol.

Seed-lac consists of minute irregular fragments, broken from the twigs and partially exhausted by water. It is of a light or dark brown color, inclining to red or yellow, feebly shining, almost tasteless, and capable of imparting to water less color than the *stick-lac*, sometimes scarcely coloring it at all. It is occasionally mixed with small fragments of the twigs.

Shellac is prepared by melting the *stick-lac* or *seed-lac*, previously deprived of its soluble coloring matter, straining it, and pouring it upon a flat smooth surface to harden. Valentine Ball (*Jungle Life in India*, N. R., June, 1880) states that the *stick-lac* is first placed between two powerful rollers, which, by a simple arrangement, admit of any degree of approximation. The lac is then crushed off and is separated from the woody portions by screening; it is next placed in large tubs half full of water and is washed by the coolies, male or female, who, standing in the tubs, and holding to a bar above with their hands, stamp and pivot about on their heels and toes until, after a succession of changes, the resulting liquor comes off clear. The disposal of the liquor drawn off at the successive washings will be spoken of farther on. The lac, having been dried, is placed in long cylindrical bags of cotton cloth, of medium texture, and about ten feet long and two inches in diameter. These bags when filled have somewhat the appearance of enormous bologna sausages. They are taken to an apartment where there are a number of open charcoal furnaces. Before each of these there are one principal operator and two assistants. The former grasps one end of the long sausage in his left hand and slowly revolves it in front of the fire, and at the same time one of the assistants, seated as far off as the sausage is long, twists it in the opposite direction. The roasting before the glowing charcoal soon melts the lac in the portion of the bag nearest the operator's hands and the twisting of the cloth causes it to drop into a trough formed of the leaves of the American aloe (*Agave americana*). When a sufficient quantity in a molten condition is ready in the trough, the operator takes it up in a wooden spoon and places it in a wooden

cylinder some eight or ten inches in diameter, the upper half of which is covered with sheet brass. The stand which supports this cylinder gives it a sloping direction away from the operator. The other assistant, generally a woman, now steps forward, holding a strip of the aloe between her hands, and with a rapid and dexterous draw of this the lac is spread out at once into a sheet of uniform thickness, which covers the upper portion of the cylinder. The operator now cuts off the upper edge with a pair of scissors, and the sheet is then lifted up by the assistant, who waves it about for a moment or two in the air till it becomes quite crisp. It is then held up to the light, and any impurities (technically called "grit") are simply punched out of the brittle sheet by the finger. The sheets, laid upon one another, are placed in packing cases, and when subjected to pressure break into numbers of fragments. The dark red liquor resulting from the washing above described is strained in order to remove all foreign materials. It is then passed into large vats, where it is allowed to settle. The sediment is subjected to various washings, and at last allowed to settle finally, the supernatant liquid being drawn off. The sediment when of proper consistency is placed in presses, from which it is taken out in the form of hard, dark purple cakes, with the manufacturer's trade-mark impressed upon them. This constitutes what is known in commerce as "lac dye." By the addition of mordants this dark purple substance yields the most brilliant scarlet dyes, which are not inferior to those produced by cochineal. Shellac is in thin fragments of various sizes, from half a line to a line thick, often somewhat curved, of a lighter or darker brown color, inclining more or less to red or yellow, shining, more or less transparent, hard and brittle, inodorous and insipid, insoluble in water, but easily and almost entirely soluble in alcohol, especially with the aid of heat. According to Oberdörffer, cold ether takes from shellac only about 5 per cent., consisting of wax, and adulteration with resins soluble in ether is thus readily detected. (See *A. J. P.*, 1861, 313.) An alcoholic solution of shellac usually needs clarification (due to suspended wax); by agitating the solution with six parts of powdered chalk, decanting and filtering, it becomes transparent.

A variety of lac is mentioned by writers, in the form of cakes, called *cake-lac* or *lump-lac* (*lacca in placentis*); but this is at present rare in commerce.

According to John, lac consists of resin, coloring matter, a peculiar principle insoluble in alcohol, ether, or water, called *laccin*, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and ether. The *laccin* is nearly or quite wanting in shellac, which also contains scarcely any of the coloring principle. Hatchett found in stick-lac 68 per cent. of resin, and 10 of coloring matter; in seed-lac 88.5 per cent. of resin, and 2.5 of coloring matter; in shellac 90.9 per cent. of resin, and 0.5 of coloring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters. R. E. Schmidt (*Ber. d. Chem. Ges.*, 1887, 1285-1303) has prepared the lac dye in a pure crystallized state. He gives it the formula $C_{16}H_{12}O_8$, and calls it *laccic acid*. It was obtained crystallized from ethereal solution. Caustic alkalies dissolve it, giving a magenta color. Baryta water forms a

violet lake. Laccic acid shows some analogy to carminic acid, but the colors they give on wool and silk are different. Laccic acid is decomposed on heating with concentrated hydrochloric acid to 180° C. (356° F.), as well as on fusing with caustic potash.

The importations of lac, crude and stick, into the United States in 1904 were 1,107,131 pounds, valued at \$324,874; of shellac in the same year, 10,934,627 pounds, valued at \$3,505,229.

Lac in its crude state is slightly astringent, and was formerly used in medicine, but at present it is not employed. Shellac is wholly inert. Stick-lac and seed-lac are used on account of the coloring principle which they contain. Shellac, as well as the other varieties, deprived of their coloring matter, is applied to numerous purposes in the arts. It is the chief constituent of *sealing wax*. The best *red sealing wax* is made by melting together, with a very gentle heat, 48 parts of shellac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common resin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. The best *black sealing wax* consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone black; the best *yellow sealing wax*, of 60 parts of lac, 12 of turpentine, and 24 of lead chromate. (Berzelius.) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and earthenware. It may be dissolved in alcohol, oil of turpentine, benzoin, or naphtha. For a method of preparing a colorless varnish from lac the reader is referred to *P. J.*, 1864, 338. Lac has been highly recommended as an adhesive material for the dressing of *wounds, ulcers*, etc. It is prepared for use by dissolving, with the aid of a gentle heat, in alcohol contained in a bottle, sufficient lac to give it a gelatinous consistence, and then closing the bottle. It is used by spreading it on the bandages.

Lactanin. *Bismuth Dilactomonotannate*.—This is a yellow, odorless, tasteless powder, insoluble in water, which has been used in *doses* of three to five grains (0.2-0.32 Gm.) in *tubercular* and other *chronic diarrhoeas* of young children.

Lactol (*Lactonaphthol*) is the lactic acid ester of β -naphthol, $CH_3.CHOH.COOC_{10}H_7$. It forms colorless crystals insoluble in water, but soluble in alcohol; used as an intestinal antiseptic.

Lactophenin. *Lactyl-phenetidin*.
 $C_6H_4 \begin{cases} OC_2H_5 \\ NH.CO.CH(OH).CH_3 \end{cases}$ —A white crystalline powder, without odor, having a feeble, bitter taste, soluble in one part in five hundred of cold water, one in eight and a half parts of alcohol, and having a melting point of from 117.5° to 118° C. (243.5° - 244.4° F.). It is produced by the action of lactic acid on phenetidin in the presence of dehydrating substances.

We have very little definite knowledge in regard to the physiological action of lactophenin, but it appears to be an active antipyretic and analgesic. It is said to be more calmative and hypnotic in its influence than is antipyrine or phenacetin. Jaquet puts it as between sulphonal and urethane as an hypnotic. When, in *pneumonia, typhoid fever*, or other infectious diseases, the nervous symptoms are very pronounced and the fever high, lactophenin would seem to be especially indicated. It is affirmed to be valuable in *rheumatism*, having specific curative properties inferior to but resembling those of the salicylates.

The statements which have been made that its use is free from danger are, however, not correct. It sometimes produces an exanthematous eruption, which may be macular or diffuse. Wenzel (*Cb. I. M.*, xvii. 1896) reports a case in which, after the patient had been taking, for two weeks, fourteen grains of lactophenin a day, there was suddenly developed violent jaundice, with dark brown urine, without fever or slowing of the pulse, with colorless stools. Similar cases had been previously recorded by Strauss, and Franz Rield (*Zeitsch. f. Heilk.*, xvi. 1895) details two. Kronig (*B. K. W.*, 1895) has reported a case of poisoning, with methæmoglobin in the blood and cyanosis, followed by rapid death. It is eliminated, at least in part, by the urine as a paramidophenol.

Lactophenin may be given in doses of from five to twenty grains (0.32–1.3 Gm.), repeated in special cases up to a drachm and a half (5.8 Gm.) in a day.

Lakes.—These paints are compounds of vegetable or animal coloring principles with alumina or other metallic oxide, and are usually obtained by adding alum or stannic chloride to the solution of the coloring matter in water, and precipitating by means of an alkali. The alumina or stannic oxide unites with the coloring matter at the moment of separation, and forms an insoluble compound. Lakes are obtained in this way from cochineal, madder, Brazil wood, seed-lac, French berries, etc.

Lamium. *Lamium album*, L.—Hemostyptic properties were long since attributed by Lusi-tanus and by Florain to the flowers of this labiate plant, and according to the more recent researches of Kalabin (*Cb. G. T.*, xx. No. 12) their decoction produces a rise of the arterial pressure due to contraction of the peripheral vessels. The extract was found to cause firm, lasting contraction of the uterus, and the saturated tincture, in doses of twenty-five to forty minims (1.6–2.5 Cc.) every two or three hours, to be useful in hæmorrhagic metritis and metrorrhagia. Its effects in puerperal hemorrhage were not pronounced.

Lantana. *Lantana brasiliensis*, Link. *Yerba Sagrada*. (Fam. Verbenacæ).—This Brazilian plant contains, according to Negrete, an alkaloid, *lantanine*, which is actively antiperiodic in doses of from fifteen to thirty grains (1.0–2.0 Gm.) in the twenty-four hours, given directly after the paroxysm. (*T. G.*, 1885.)

Lanthanum Nitrate.—*Lanthanii Nitras*, $\text{La}_2(\text{NO}_3)_6 \cdot 12\text{H}_2\text{O}$, occurs in large rose-colored prisms which are soluble in water and alcohol. This salt is employed as an antiseptic, preventing the growth of bacteria when used in solutions of the strength of 1 in 2000. (See *Cb. B.*, 1897, xxi.)

Larch Bark. *Laricis Cortex*, Br. 1885. *Ecorce de Mélèze*, Fr. *Lärchenrinde*, G.—The bark of *Larix europæa*, DC. (*L. Larix* (L.), Karst., *Pinus Larix*, L.), of the fam. Conifera, was found by Aldridge to contain gum, starch, resin, and tannic acid of the kind which precipitates the salts of iron olive-green. John Stenhouse has obtained from it a peculiar volatile acid, *larixinic acid* (*larixine*). (For method of separation see 16th edition, *U. S. D.*) *Larixinic acid* occurs in beautiful white, lustrous crystals, often more than an inch long, of a peculiar somewhat empyreumatic odor, and a slightly bitter and astringent taste, inflammable, volatilizing at 93° C. (199.4° F.) and melting at 153° C. (307.4° F.), soluble in 87.88 parts

of water at 13.3° C. (56° F.), very soluble in boiling water, soluble in cold but much more so in hot alcohol, and sparingly soluble in ether. It readily crystallizes from its solutions. A very singular and characteristic property is that of forming, when added, in strong solution, in excess, to baryta water, a bulky, transparent, gelatinous precipitate, occupying the whole measure of the liquids if concentrated. The probable formula of the acid is $\text{C}_{10}\text{H}_{10}\text{O}_6$. The inner larch bark possesses astringent and gently stimulant properties, and is supposed to have a special tendency to the mucous membranes. It has been found particularly efficacious in *purpura* and other hæmorrhagic affections, especially hæmoptysis, and has been given in bronchitis with copious expectoration, and in diseases of the urinary passages. It has been used also, mixed with soap and glycerin, as a local remedy in *psoriasis*, *chronic eczema*, and other cutaneous affections. Of the extract from three to five grains (0.20–0.32 Gm.), of the tincture from thirty minims to a fluidrachm (1.8–3.75 Cc.) or more may be given every three or four hours.

Lathyrus. *Lathyrus sativus*, L. (Fam. Leguminosæ).—The *White or Chickling Vetch*, *Jarosse*, *Gesse*, which is used in Europe as a food both by man and animals, produces, when taken too freely, a condition known as *lathyrismus*. Horses which have been fed on the plant for a considerable period drop while performing the lightest work, in consequence of paralysis of the hinder extremities, and in many cases death has followed from bilateral paralysis of the recurrent laryngeal nerves and consequent asphyxia. This laryngeal affection does not occur in the human subject, and death very rarely takes place. In man the muscles of the lower extremities below the knee are apt to be especially affected, the abductors more than the adductors. The muscles of the face, neck, and upper extremities are very rarely, if ever, attacked. The reflexes and the general sensibility are usually not influenced; but Giorgieri has seen the tendon reflexes increased. According to Cantani, the galvanic contractility of the paralyzed muscle is altered, and the transverse markings of the muscles are nearly obliterated by fat globules. In fatal cases the spinal cord has been found normal. Astier obtained from the seeds a poisonous alkaline volatile liquid. According to him, this, being volatile, is not present in preparations such as pressed cakes made at a high temperature, which are consequently not poisonous. If, however, such cakes have been prepared at low temperature, they exhibit toxic properties, owing to the retention of the toxic principle. This is in conformity with the experience of the peasants in some parts of Europe, who mix the ground white vetch seeds with wheat flour, and boil the mixture for food.

Laurotetanine.—This alkaloid, $\text{C}_{19}\text{H}_{23}\text{NO}_5$, or $\text{C}_{16}\text{H}_{13}\text{O}_2(\text{O} \cdot \text{CH}_3)_3\text{NH}$, according to Schmidt, has been found by Greshoff in a species of *Malapaenna* (*Tetranthera*) and in other plants belonging to the Lauracæ. It is said to be a powerful poison, acting like strychnine on the spinal cord. It gives with Froehde's reagent a magnificent indigo-blue color, which on the addition of water changes to yellow; with Erdmann's reagent, a transitory bright blue color, becoming brown, and with more nitric acid it gives immediately a bright red-brown, and with pure nitric acid a dirty brown. It is soluble in excess of alkali. (*P. J.*, vol. xxi. 1891.)

Laurus. *Laurus nobilis*, L. *Sweet Bay*. *Laurier commun*, Fr. *Lorbeer*, G.—The Bay tree, *Laurus nobilis*, is an evergreen tree of the fam. Lauracæ, inhabiting the countries bordering on the Mediterranean. The leaves are alternate, on short petioles, oval-lanceolate, entire, sometimes wavy, veined, of a firm texture, smooth, shining, deep green upon their upper surface, paler beneath. They have a fragrant odor, especially when bruised, and a bitter, aromatic, somewhat astringent taste. They yield by distillation a greenish-yellow volatile oil. The volatile oil, of which the fruit yields 0.23 per cent., has a sp. gr. 0.88, and is solid at 0° C. (32° F.). It is largely composed of oxygenated compounds. The constituents thus far recognized are *myrcene*, *phellandrene*, *methyl-chavicol*, *citral*, *methyl-eugenol*, *chavicol*, and *eugenol*. (*Schim. Rep.*, April, 1897.) Water distilled from the leaves has their peculiar odor. The berries when dried are black and wrinkled, and contain two oval fatty seeds within a thin, friable envelope; or they may be considered as drupes, with a kernel divisible into two lobes. They have the same aromatic odor and taste as the leaves, but are more pungent. Besides an essential oil, they contain a fixed oil, which, as obtained by expression from the fresh fruit, is of a greenish color, and aromatic odor from retained volatile oil. One of its chief constituents is the ether of *lauric acid*, the so-called *laurostearine*, $C_3H_5(C_{12}H_{23}O_2)_3$, which fuses at 45° C. (113° F.). The free acid may be obtained from this by saponification. It cannot be distilled without decomposition. Another constituent of the crude fat is *laurin*, $C_{22}H_{40}O_8$, which can be extracted by alcohol. It forms neutral, easily fusible prisms without odor or taste. Lard, impregnated with the odorous principle of the berries, and colored green by chlorophyll or sometimes by indigo and turmeric, is said to be often substituted for the genuine expressed oil. This may be detected by boiling alcohol, which dissolves the true oil. The leaves, berries, and oil are excitant and narcotic, but are never used internally as medicines, and in this country are scarcely employed in any manner. Their chief use is to communicate a pleasant odor to external remedies.

Lavender Flowers. *Lavandula*. U. S. 1880. *Lavandula angustifolia* (L.), Mill. (*L. officinalis*, Chaix, *L. vera*, DC.) *Lavender*. *Flores Lavandulæ*, P. G. *Lavande*, *Fleurs de Lavande*, Fr. *Lavandelblumen*, *Lavandelblüthen*, G. *Lavendola*, It. *Espliego*, *Alhucema*, Sp.

Lavender is a small labiate shrub. The plant is a native of Southern Europe, and covers vast tracts of dry and barren land in Spain, Italy, and the south of France. In England and America it is very largely cultivated. For method of culture and detailed descriptions of the various varieties that have been educed, see *B. M. S. J.*, Aug. 1873, 165. The cultivation of lavender has become an important industry, and inasmuch as that produced in England has the best reputation, the following extracts from a paper by J. C. Sawyer (*P. J.*, Aug. 8, 1885, p. 125, and Feb. 15, 1890, p. 659) will be found useful in view of the fact that attempts are being made to cultivate the finer qualities of lavender in the United States.

"The first plants experimented on developed in the form of dense level topped rounded tufts of foliage with comparatively few flower heads. Each flower head formed a continuous spike, except the lowest whorl or verticillaster, which is separated from the upper portion of the spike by a short distance. This variety neither grows

rapidly nor flowers freely, and the perfume is not so fragrant as in the others. Another variety was then tried, in which nearly all the floral whorls are distinct, so as to form an uninterrupted spike. This variety grew rapidly, flowered freely and was found to be delightfully fragrant, and was, therefore, adopted. It has the disadvantage, however, that the plant soon forms woody stems which, if the plants are much exposed to wind, easily break, and loss of flowers results. It should be observed that all the varieties presented the characteristic rhomboidal bracts of the true lavender. It is obvious, therefore, that the cultivation of lavender requires constant attention and habits of close observation on the part of the cultivator, and that the quality of the oil produced is likely to depend not only on the care with which the oil is distilled, but on cultivating only the best varieties, as well as on the character of the soil. The chalky soil on the hills near Brighton, where Sawyer experimented, seemed peculiarly suited to the culture of lavender.

It is necessary to grow the lavender sufficiently far apart to allow of ready passage between the rows, as the plants soon spread their branches, and it is otherwise difficult, without injuring the plants, to carry the crop of flowers, if required for distillation. The collection has frequently to be done rapidly when the flower is arrived at a certain stage of maturity, and dry weather must be selected for the work. When the plant once begins to flower the blossoms are shed rapidly, and in damp weather the spikes carry much water and lose fragrance.

The flowers deprived of as much stalk as possible should be distilled, *without previous maceration*, the same day as cut, and not left in heaps as the flowers rapidly ferment and the character of the oil is quite changed. The water passing over with the oil should not be returned to the still; the very small quantity of oil saved by doing so would not compensate for the herbaceous flavor communicated to the next running."

Lavender flowers have a strong fragrant odor, and an aromatic, warm, bitterish taste. They retain their fragrance long after drying. Alcohol extracts their virtues, and a volatile oil upon which their odor depends rises with that liquid in distillation. Hager obtained from a pound of the fresh flowers from half a drachm to two drachms of the oil. Lavender is an aromatic stimulant and tonic, but is seldom given in its crude state. The products obtained by its distillation are much used in perfumery, and the volatile oil is official. (See *Oleum Lavandulæ Florum*, p. 850.)

Lawsonia. *Lawsonia inermis*, L. (*L. alba*, Lam.) *Henna Plant*.—This is a shrub of the fam. Lythracæ, growing in the Levant, Egypt, Persia, and India, and well known as the source of a dye-stuff denominated *henna*, much used throughout the Mohammedan countries of the East. It is largely cultivated in Egypt. The flowers have a strong, pungent odor, and a distilled water prepared from them is used as a cosmetic. The fruit is thought to have emmenagogue properties. The powdered leaves, under the name of *henna*, are used to stain golden yellow the feet and hair of women of the harem. Abd-el-Aziz of Cairo, Egypt, found in it a brown substance, of a resinoid fracture, having the chemical properties which characterize the tannins, and therefore named by him *hennotannic acid*. (*J. P. C.*, 1863, 35.) *Henna* is employed both internally and locally, in *jaundice*, *leprosy*, and affections of the skin.

Lead Oxide, Red. *Plumbi Oxidum Rubrum*. Red Oxide of Lead. Red Lead. *Minium*, P. G. *Deutoxide de Plomb*, *Oxide Rouge de Plomb*, *Minium*, Fr. *Mennige*, G. *Minio*, It., Sp.—Red lead is prepared on the large scale in a furnace, with the floor slightly concave and the roof arched, presenting a general resemblance to a baker's oven. The lead is placed on the floor, and gradually raised to a red heat, whereby it melts and becomes covered with a pellicle of monoxide, which is removed by means of a long iron scraper, and the pellicles, as they successively form, are scraped off until the whole of the metal has been converted into them. The product is subjected to further calcination, with occasional stirring, for some time, in order to oxidize any remaining particles of metallic lead; it is thus rendered yellow, and constitutes lead monoxide, or *massicot*.

This is taken out of the furnace, thrown upon a level pavement, and cooled by being sprinkled with water. It is next reduced to fine powder by trituration and levigation, and dried, and in this state is introduced into large, shallow, square tin boxes, which are placed in another furnace, closed from the air, and heated nearly to redness, the heat being allowed gradually to fall during a period of from twenty-four to thirty hours. At the end of that time the lead monoxide will have combined with an additional quantity of oxygen, and become the red oxide. This is taken out, and, after it has passed through a fine wire sieve, it is packed in barrels for the purposes of commerce.

The above is an outline of the French process for making red lead. In England and the United States the calcination of the monoxide is not performed in tin boxes, but by returning it to the furnace in which it was first calcined. H. N. Warren recommends the following process for preparing pure red lead. Either litharge or lead sulphate from vitriol tanks, etc., is introduced into canvas bags, through which is inserted a lead sheet. These bags are now immersed in diluted sulphuric acid, and connected respectively to sheets of iron; the sulphate or other plumbic compound contained therein is thus speedily and completely reduced to the spongy metal, the bags afterwards connected alternately by their lead plates and exposed to an electric current, the positives being thus completely converted into peroxide, while the temporary accumulator thus produced is again emptied of its current into further quantities of spongy metal, thus producing more peroxide. This process, when rightly conducted, yields an absolutely pure oxide on a cheap scale. (*Chem. News*, Sept. 18, 1896, 144.)

Properties.—Red lead is in the form of a heavy, scaly powder, of a bright red color, with a slight shade of orange. Its sp. gr. is about 9. When exposed to heat it gives off oxygen, and is reduced to the state of monoxide. It is sometimes adulterated with red ferric oxide and red bole, substances which may be detected by treating the red lead with nitric acid and testing the nitric solution with tincture of galls. This reagent will produce a black precipitate, in consequence of the iron being dissolved by the nitric acid. If brick dust be present, it will be left undissolved upon boiling the suspected specimen in water, with sugar and a small quantity of nitric acid. When free from impurities it is wholly reduced on charcoal by means of the blow-pipe, giving a globule of metallic lead. It is completely soluble in highly

fuming nitrous acid. When treated with nitric acid it is resolved into monoxide, which dissolves, and dioxide, which remains in the form of a dark brown powder.

The red lead of commerce may be considered as a mixture of what may be called the true red oxide and variable proportions of monoxide. That this is its nature is rendered probable by the action of cold diluted acetic acid, not used in excess, which takes up a variable quantity of monoxide, leaving a portion unchanged in color, which may be deemed the pure red oxide. This latter, when analyzed by nitric acid, has been proved, by the coincident results of Dalton, Dumas, and Phillips, to consist of three atoms of lead and four of oxygen, equal to $2\text{PbO} \cdot \text{PbO}_2$ (Dumas), or $\text{PbO} \cdot \text{Pb}_2\text{O}_3$ (Winckelblech). Mulder gives $\text{Pb}_4\text{O}_6 = 3\text{PbO} \cdot \text{PbO}_2$, or $2\text{PbO} \cdot \text{Pb}_2\text{O}_3$, as the usual composition of red lead.

Red lead enters into no official preparation. In the arts it is used chiefly as a paint, for protecting metal surfaces, in the manufacture of flint glass, and in cements for metal joints.

Lead Saccharate. *Plumbi Saccharas*. *Saccharate of Lead*.—Lead saccharate is made by saturating a solution of saccharic acid in water with freshly precipitated lead carbonate gradually added. As the acid becomes saturated, the lead saccharate falls in the form of a white powder, being insoluble in cold water, and but very sparingly soluble in that liquid boiling hot. From this E. Hoskins prepared his *lead nitro-saccharate*, by dissolving the saccharate in diluted nitric acid, containing only one part of the acid in twenty parts of the mixture, filtering the solution, and gradually evaporating. The nitro-saccharate is deposited in yellow crystals of the form of regular six-sided plates or prisms. By dissolving one grain of this salt, with five drops of pure saccharic acid, in a fluidounce of distilled water, a solution was obtained which, though slightly acid to test paper, was perfectly bland. This solution has been used to dissolve urinary *calculi*. (See Pereira's *Mat. Med.*, 3d edition, 755.)

Lead Tannate. *Plumbi Tannas*.—This is obtained by precipitating a solution of tannin with one of lead acetate, added drop by drop. It has been used locally in *chronic inflammations of the joints, ulcerations, bed sores, and sore nipples*, in 20 to 40 per cent. ointments. (*Med. Rec.*, 1875, 575.) The preparation here described is a bitannate. Other lead tannates exist.

Lecithin. $\text{C}_{42}\text{H}_{84}\text{NO}_3\text{P}$.—The class of lecithins is now known to be widely distributed in both animal and vegetable tissues, although most familiar in its occurrence in the nerve tissues and embryonic cells.

The animal lecithin is *choline di-stearyl-glycerophosphate*, while the vegetable lecithin seems to be *betaine di-oleyl-glycerophosphate*; that is, the widely distributed vegetable base *betaine* (*oxyneurine*) replaces the choline of egg lecithin and the oleic acid radical appears instead of that of stearic acid.

Vegi-lecithin has been studied chemically by C. Gordon Richardson. Besides the replacement of the choline by betaine and the difference in the fatty acids, it differs from *ovi-lecithin* in not being precipitated by acetone and being quite insoluble in alcohol, but soluble in all proportions in cold ether. Otherwise it is readily soluble in all the solvents of *ovi-lecithin*. It seems to resemble somewhat the *cephaline* of Thudichum, which was obtained from the brain tissue.

Lecithin, as has been shown by H. C. Wood, Jr. (U. P. M. B., May, 1902), is not poisonous. Danilewski has found that in young animals it causes an increase in the number of red corpuscles and a gain in weight more rapid than normal. Sersono, in a series of careful studies on human beings, obtained a gain of bodily weight despite an increased output of nitrogen, and an augmentation of the number of red corpuscles without, however, any increase in the percentage of hæmoglobin; the phosphatic elimination did not keep pace with the increased ingestion of phosphorus.

Lecithin has been employed in practical medicine by Sersono, Gilbert, Fournier, and other observers, in *tuberculosis* and *neurasthenia*, with favorable results; the most marked amelioration being an increase in the weight and an improvement in the subjective condition. Lancereaux and Paulesco commend it in *diabetes*, and it has been employed successfully in *chlorosis*. Most of the above observers obtained their lecithin from egg yolks; Moriggia, indeed, simply injects a solution of egg yolk in normal salt solution directly. Numerous agents decompose lecithin into its constituent parts—glycerin-phosphoric acid, choline, and fatty acids.

Choline is a substance of considerable toxic power, and is chemically and physiologically very closely allied to the animal alkaloid *neurine*, a toxic compound discovered by Strecker (*Ann. Ch. Ph.*, cxxiii.) and shown by Brieger (*Ueber Ptomaine*, Berlin, 1895) to occur in decomposing meat. In the frog, choline produces paralysis, partly by its depressing action upon the spinal cord, but largely by its paralytic effect upon the motor nerve endings. In the mammal fatal doses kill by the arrest of respiration. It produces slowing of the pulse and a slight temporary rise of blood pressure, followed by a secondary fall. It is a marked stimulant to involuntary muscle fibres, and to many glands, especially the salivary.

Ledum. *Ledum palustre*, L. Marsh Tea. *Rosmarinus Sylvestris*. Marsh Cistus. Wild Rosemary. *Lédon*, *Romarin sauvage*, Fr. *Porsch*, *Sumpfporsch*, *Wilder rosmarin*, G.—A small evergreen ericaceous shrub, growing in swamps and other wet places in the northern parts of Europe, Asia, and America, and in the mountainous regions of more southern latitudes. The leaves have a balsamic odor, and an aromatic, camphorous, bitter taste, and contain, among other ingredients, volatile oil and tannin. For the properties of the volatile oil, see *J. P. C.*, 4e sér., xx, 244; also *Proc. A. Ph. A.*, xxv, 154. It contains *ledum camphor*, a stearopten, together with valeric and other volatile acids, and *ericinol*, $C_{10}H_{16}O$. The tannin has been named *leditannic acid*, $C_{15}H_{20}O_8$. On boiling with dilute mineral acids it is decomposed, and *ledixanthin*, $C_{30}H_{34}O_{13}$, separates as a yellowish or reddish powder. (Thal, *Ph. Z. R.*, 1883, 268.) Thal also extracted *ericolin*, $C_{34}H_{56}O_{21}$. This is a glucoside, which on heating with diluted sulphuric acid decomposes into sugar and *ericinol*, $C_{10}H_{16}O$, a colorless, peculiar-smelling oil, which turns brown in the air, owing to oxidation. The leaves are thought to be narcotic and diaphoretic, and have been employed in *dysentery* and in various cutaneous affections, particularly *leprosy* and *scabies*. In complaints of the skin they are used both internally and externally, in the form of decoction. In Germany they are sometimes substituted for hops in the preparation of beer. *Ledum grœnlandicum*, Oeder

(*L. latifolium*, Ait.), or *Labrador tea*, which is a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern part of the United States. The leaves have an agreeable odor and taste, and are esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war for independence.

Leek. *Porrum*. *Porreau*, Fr. *Lauch*, G. The bulb of *Allium Porrum*, L. (Fam. Liliacæ.) The leek is a biennial bulbous plant, growing wild in Switzerland; and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive, pungent odor and an acrid taste, dependent on an essential oil, of which allyl sulphide, $(C_3H_5)_2S$, is the main ingredient. The bulb, which is the medicinal portion, consists of concentric layers, like the onion, which it resembles in medicinal properties, though somewhat milder. It is generally stimulant, with a direction to the kidneys. Dose of expressed juice, a fluidrachm (3.75 Cc.).

Lenigallol. *Pyrogallol Triacetate*. $C_6H_3(O.C_2H_3O)_3$.—This is a white powder, insoluble in water, and is used in paste form. This derivative of pyrogallic acid has been highly commended as a local remedy in acute and moist *eczema*, and in *pityriasis rosea*. It is said not to act well in the dry desquamating *eczema*. In the strength of 30 to 50 per cent. it is also useful as a keratolytic.

Eugallol (*pyrogallolmonacetate*), a second derivative of pyrogallic acid, is affirmed to be of great value in *psoriasis*, acting like chrysarobin but less irritating. It is non-toxic. The addition of acetone produces a liquid thin enough to be painted over a diseased part and to leave on evaporation a tense elastic pellicle.

Leonotis. *Leonotis Leonurus*, R. Br.—This handsome tropical labiate is said to possess purgative and emmenagogue properties. (See *P. J.*, May, 1885.)

Leonurus. *Leonurus Cardiaca*, L. Common Motherwort. *Agripaume*, *Cardiaire*, Fr. *Herzspann*, *Wolfstrapp*, G.—An aromatic perennial labiate herb, growing wild in this country in waste places, around dwellings, etc., whose infusion or decoction is sometimes used in *amenorrhœa* and sudden suppression of the *lochia*.

Lepargyræa. *Lepargyræa argentea* (Nutt.), Greene (*Shepherdia argentea*, Nutt.). *Buffalo Berry*. *Bull Berry*. *Grains de Bœuf*, Fr.—The acidulous fruit of this plant, of the fam. *Elæagnacæ*, produced in great profusion in the region of the upper Missouri, is largely used as an article of food. According to Henry Trimble, it contains a little more acid than currants. (*A. J. P.*, Dec. 1883.)

Lewisia. *Lewisia rediviva*, Pursh. *Spathum Chita*. *Bitter Root*.—The roots of this plant, of the fam. *Portulacacæ*, abundant in the Northwestern United States, are very widely used by the Indians as an article of food. For analysis and description, see *A. J. P.*, 1889.

Liantral.—This substance is an extract of coal tar, obtained by treating with benzene, filtering from insoluble residue, and subsequently evaporating the benzene at a temperature not exceeding 80° C. (176° F.). It is a brownish-black viscous fluid which is insoluble in water, freely soluble in benzene, but dissolving only sparingly in fats, ethereal oils, alcohol, ether, acetone, petroleum benzin, and mixtures of these substances. Liantral has been commended by various clinicians as

a substitute for coal and wood tars in the treatment of *eczema* and allied skin diseases. It is said to resemble wood tar in its action, but to be more energetic. It has been used in ten per cent. solution with olive oil, applied with a brush, or in the form of a dusting powder made by triturating to dryness with the aid of a little ether, starch, or talc.

Liatris. *L. spicata*, Willd. *Lacinaria spicata* (L.), Kze. *Gay-feather*. *Devil's Bite*. *Colio Root*. *Button Snakeroot*.—An indigenous perennial composite plant growing in natural meadows and moist grounds throughout the Middle and Southern States. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple, compound flowers, appearing in August. The root is said by Schoepf to have a terebinthinate odor, and a warm, bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful as a local application in *gonorrhœa* and *sore throat*. The leaves of the allied *Trilisa odoratissimus* (Walt.), Cass. (*Liatris odoratissimus*, Willd.), or *Vanilla leaf*, are very largely employed in the Southern United States to flavor tobacco, and to preserve clothing, etc., from moths. As a preservative it is worthless. The agreeable odor is due to *coumarin*, $C_9H_8O_2$, which may be frequently noticed in crystals upon the surface of the smooth spatulate leaves. (A. J. P., March, 1875; Sept., 1881; xlvii. 116; N. R., 1882, 66.) The roots of *L. scariosa*, Willd. (*Lacinaria scariosa*, Hill) and *L. squarrosa*, Willd. (*Lacinaria squarrosa*, Hill) (*rattlesnake's master*), have been employed to cure the bite of the rattlesnake. According to Wm. P. C. Barton, all the tuberous-rooted species of *Liatris* are active diuretics.

Lignol.—This is an oily or tarry substance which is said to be obtained by the dry distillation of a bituminous fossilized wood. Lignol is asserted to be in bactericidal power equal to the 5 per cent. solution of phenol, and is recommended in *eczema*, *acne*, *pruritus*, and other chronic skin diseases, and in doses of fifteen minims (0.9 Cc.) in pulmonary tuberculosis. Also, in chronic irritation of the genito-urinary tract.

Ligroïne. *Ligroïn*.—This name has been applied to a petroleum product which is chiefly used as a solvent. It boils between 80° C. and 120° C. (176° – 248° F.) and has a specific gravity varying between 0.710 and 0.730 (67° – 62° B.).

Ligusticum. *Radix Levistici*, P. G. *Livèche*, *Ache de Montagne*, Fr. *Liebstockel*, G.—Several species of this umbelliferous genus are employed as domestic remedies. The allied *Levisticum officinale*, Koch (*Ligusticum Levisticum*, L.), or *lovage*, of the south of Europe, is aromatic in all its parts, but only the roots and seeds are used. The seeds are small, ovate-oblong, somewhat flattened, curved, strongly ribbed and of a yellowish-brown color. The medicinal properties of lovage are closely analogous to those of angelica. It is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion. The coloring principle has been isolated by M. J. Nicklès, who gives it the name of *ligulin*, and suggests an important application of it that may be made in testing drinking water. If a drop of its alcoholic or aqueous solution is allowed to fall into distilled water, it imparts to the liquid its own fine crimson-red color, which undergoes no change; but if limestone water be substituted, the red color disappears in a few

seconds, and is followed by a beautiful blue. (J. P. C., 1859, 329.) The root of *Ligusticum sinense*, under the name of *kao-pên*, is largely used by the Chinese. In the Northwestern United States the large aromatic roots of *Ligusticum filicinum*, S. Wats., *Osha*, *Colorado cough-root*, are used to a considerable extent as stimulating expectorants. (See A. J. P., 1890 and 1891.)

Ligustrum. *L. vulgare*, L. *Troène*, Fr. *Rain-weide*, *Hartriegel*, G. *Privet*.—A shrub of the fam. Oleaceæ, from four to ten feet in height, growing wild both in Europe and the United States, usually in hedges and by the roadside. The leaves, which have an astringent, bitter taste, and the flowers, which are small, snow-white, and of an agreeable odor, have been used in the form of decoction in *sore throat* and *aphthous* and *scorbutic ulceration of the mouth*. The berries are black, have a sweetish bitter taste, and are said to possess purgative properties, and to color the urine brown. They are sometimes used for dyeing. Death in a child between two and three years old is recorded by James Cheese (P. J., 2d ser., viii. 607), as due to the eating of privet berries. The bark was analyzed by M. G. Polex, who found a peculiar substance, which he denominated *ligustrin*, insoluble in ether and absolute alcohol, but soluble in water and diluted alcohol. Strong sulphuric acid gives with *ligustrin* a deep indigo-blue color. Kromayer (A. Pharm., (2) cxiii. 19) proved that Polex's *ligustrin* was only impure *syringin*, $C_{19}H_{28}O_{10} + H_2O$. The large white crystals become anhydrous at 115° C. (239° F.), and fuse at 212° C. (413.6° F.). He found in addition (see Kromayer, A. Pharm., (2) ci. 281) mannite, sugar, muco-saccharine matter, starch, chlorophyll, bitter extractive, bitter resin, tannin, albumen, and salts. (A. J. P., xii. 347.) Kromayer found besides the *syringin* a crystallized bitter principle, fusing at a little over 100° C. (212° F.), which he named *ligustron*.

Lilium. *Lilium candidum*, L. (Fam. Liliacæ.) *Common White Lily*.—This well known plant is a native of Syria and Asia Minor, but has been long cultivated in gardens. The bulb, which consists of imbricated fleshy scales, is without odor, but has a peculiar, disagreeable, somewhat bitter, and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle. In the recent state it is said to have been employed with advantage in *dropsy*. Vomiting, purging, drowsiness, etc., are said to have been produced in a little girl by the pollen of the *tiger lily*, *L. tigrinum*, Andr. (Jeffries Wyman, Am. J. M. S., 1863.)

Linaria. *Linaria Linaria* (L.), Karsten. *Linaria vulgaris*, Mill. *Antirrhinum Linaria*, L. *Common Toadflax*. *Butter and Eggs*. *Ramsted*. *Snapdragon*. *Linair commune*, Fr. *Leinkraut*, *Flachskraut*, *Löwenmaul*, G.—This is a perennial herbaceous plant very common in America, Europe, and Asia. It should be collected when in flower, dried quickly, and kept excluded from the air. When fresh it has a peculiar, heavy, disagreeable odor, which is in a great measure dissipated by drying. The taste is herbaceous, weakly saline, bitter, and slightly acrid. This plant is said to be diuretic and cathartic, and has been used in *dropsy*, *jaundice*, and *cutaneous eruptions*. It is most conveniently employed in infusion. The fresh plant is sometimes applied, in the shape of poultice or fomentation, to *hemorrhoids*, and an ointment of the flowers has been

employed for the same purpose, and also locally in diseases of the skin. The flowers are used in Germany as a yellow dye.

Linden.—Boussingault calls attention (*J. P. C.*, 4e sér., xv.) to a saccharine exudation which occurs upon the leaves of the European Linden (*Tilia europæa*, L.), which he has found to have the same composition as *manna* of Mount Sinai.

Lint. *Lintum Carptum*. Charpie, Fr., G. The term lint is applicable to a substance prepared from linen. It is in fact linen made soft and somewhat fleecy by various mechanical processes, so as to render it suitable for the dressing of wounds. The qualities required in good lint are,—1, perfect softness, to prevent mechanical irritation to the wound; 2, looseness of texture, to render it capable of absorbing the secretions from the surfaces to which it is applied; 3, a certain tenacity, so that it may receive unctuous dressings, yet with a facility of being torn in one direction; and, 4, sufficient firmness of fibre to prevent small portions from being easily separated and remaining as foreign bodies in the wound. As formerly and still frequently made for domestic purposes, it consists of old linen scraped by means of a knife with the hand and thus brought into a soft flocculent state, almost destitute of visible fibres. It is obvious that, though this answers some of the above requisitions, it entirely fails to answer others, and is unfit for general surgical use. It will not readily admit of the application of cerates, and must very often leave portions of its substance in the wound, to serve as future sources of irritation. Much better is the old-fashioned lint, made by machines worked by the hand. This was formerly made in large quantities. Old linen was used for the purpose, such as shirts, sheets, table cloths, etc., and generally in irregular pieces. This was first cleansed thoroughly by washing with soap and water, or by boiling with a weak lye of soda or pearlsh. Sometimes, when colored, it was bleached before being washed. Thus prepared, it was operated on by a simple machine, in which the rag, wrapped round a cylinder, was submitted to the interrupted action of a knife made to descend upon it at intervals of one-eighth of an inch, so as to cut the thread in one direction. On being removed from the machine, the cut ends of the thread became untwisted and loose, giving a flossy character to the fabric. To render it smooth, it was passed through rollers, and its ragged edges were trimmed. Of course it had different degrees of fineness according to the character of the rags used, and this diversity rendered it fit for different purposes, the finer pieces being used merely as a dressing with unctuous matter to exclude the air, while the thicker were better adapted to the absorption of the liquid secretions.

In the progress of improvement, machines were invented and patented for manufacturing lint on the large scale. Thus made, it is distinguished in commerce as *patent lint*. This is generally prepared out of cloth manufactured for the purpose, and therefore has whatever advantage may be derived from uniformity of shape and consistence. In other respects it is doubtful whether it has any superiority over the old-fashioned article; especially as, in consequence of competition, cotton, being the cheaper article, has frequently been in part or altogether substituted

for linen. It is said that lint may be rapidly prepared by attaching a piece of linen to the toothed cylinder of the common carding machine, used in mills.

Cotton is in several respects inferior to linen for the preparation of lint, and, unless its presence in any manufactured article sold by this name be made known, it should be looked on as a fraudulent substitution. Its fibre is less soft and therefore more likely to irritate; it has much less absorbing power, and it conveys heat less rapidly. The following are methods by which it may be distinguished (Elsner): 1. A linen thread when held erect, and set on fire, appears, after the flame is extinguished, in a smooth continuous form, while cotton thread similarly treated has a tufted aspect. 2. Under a microscope which magnifies 300 diameters, the linen fibre appears to be a straight nearly solid cylinder, with a slender central canal; the cotton, flattened as a piece of tape, with a wide canal, and often twisted like a corkscrew. 3. The potassium test, proposed by Böttger, consists in exposing the doubtful substance to the action of a boiling concentrated solution of potassium hydroxide. If made of linen, it will in two minutes assume a deep yellow color; if of cotton, it will either remain colorless, or will become very faintly yellow, and if the texture be composed of both, it will exhibit a streaked or mottled aspect. The examination must be quickly made, as the yellow color of the potassium becomes faint with time. 4. Sulphuric acid dissolves the linen fibre, while it leaves that of cotton little changed. 5. Linen thoroughly oiled has the transparent appearance of oiled paper; cotton remains white and opaque. 6. Tinctures of all organic red dye-stuffs, as cochineal, madder, etc., will give a much deeper color to linen than to cotton, and cause a mottled appearance when the two are mixed.

Tow, and hemp in the state of *oakum*, have been employed for dressing wounds; but they are only applicable as exterior dressings to absorb the pus, when the discharge of this is very copious. L. A. Sayre prefers picked oakum to lint as more absorbent. (*B. M. S. J.*, lxvii. 84.) *Charpie*, so much used by French surgeons, generally consists of bundles of straight threads, each four or five inches long, made by unravelling old rather coarse linen.

Linum catharticum, L. *Purging Flax*.—Purging flax is a European annual of the fam. *Lineæ*, six to eight inches high. The whole plant is very bitter and somewhat acrid, and imparts its virtues to water, which acquires a yellow color. It appears to owe its activity to a peculiar drastic principle, which has received the name of *linin*, and which is afforded most largely by the plant after the flower has fallen. Schroeder (*N. R. Pharm.*, xi. 11) obtained it in lustrous, white, silky crystals, which are neutral in reaction and have a strong persistent bitter taste in alcoholic solution. Purging flax has enjoyed some reputation in Europe as a gentle cathartic, useful in *muscular rheumatism*, *catarrhal affections*, and *dropsy* with disease of the liver. *Dose* of the extract, from four to eight grains (0.26–0.5 Gm.); of the powder, one drachm (3.9 Gm.).

Liparin.—A mixture of ninety-four parts of olive oil and six parts of oleic acid, which has been used as a substitute for cod liver oil. *Dose*, from one teaspoonful to half a fluidounce (3.75–15.0 Cc.).

Lippia. *Lippia Mexicana*. (Probably *Cedronella mexicana*, Benth., of the fam. Labiate.)—A Mexican evergreen shrub, the leaves and stalks of which have been used in medicine as a demulcent and expectorant. Podwysotzki analyzed the herb, and found it to contain tannin, a quercetin-like principle, liquid volatile oil, and a camphor-like body which he named *lippiol*. (*Proc. A. Ph. A.*, 1886, 400.) *Dose* of concentrated tincture (1 to 4), from a half to one fluidrachm (1.8–3.75 Cc.).

Liquidambar. *Liquidambar styraciflua*, L. *Sweet Gum*.—An indigenous tree (Fam. Hamamelidaceæ), growing in different parts of the United States from Connecticut to Florida, and flourishing also in Mexico, where, as well as in our Southern States, it sometimes attains a great magnitude. In warm latitudes a balsamic juice flows from its trunk when wounded. This has attracted some attention in Europe, where it is known by the name of *liquidambar* or *copalim balsam*, and is sometimes, though erroneously, called *liquid storax*. It is not afforded by the trees which grow in the Middle Atlantic States, but is obtained in the Western States bordering on the Ohio, and southward as far as Central America. It is a liquid of the consistence of thin honey, more or less transparent, of a yellowish color, of a peculiar, agreeable, balsamic odor, and a bitter, warm, and acrid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker color. It is sometimes collected in the form of tears, produced by the spontaneous concretion of the exuded juice. According to Bonastre, it contains a colorless volatile oil, a semi-concrete substance which rises in distillation and is separated from the water by ether, a minute proportion of benzoic acid, a yellow coloring substance, an oleoresin, and a peculiar principle, insoluble in water and cold alcohol, for which Bonastre proposed the name of *styracin*. The styracin of Bonastre has since been found to be *cinnamyl cinnamate*, $C_9H_9 \cdot C_9H_7O_2$, which is found together with the *ethyl, benzyl*, and other esters of cinnamic acid. Examined by W. P. Creecy of Mississippi, it was found to contain cinnamic acid as the prominent acid ingredient, besides a volatile odorous principle melting at 65° C. (149° F.) and smelling of vanillin, and 30 per cent. of a hard resin (according to W. von Miller, *storesin*, $C_{36}H_{55}(O H)_3$). If the storesin be repeatedly extracted with diluted potassium hydroxide solution, it is separated into *α-storesin*, which is amorphous and melts at from 160° to 168° C. (320°–334.4° F.), and *β-storesin*, which forms white flocks melting at from 140° to 145° C. (384°–393° F.). Of these, the *β-resin* is first extracted, while the residue is nearly pure *α-resin*. The volatile oil mentioned above contains a hydrocarbon, *styröl* or *cinnamene*, C_8H_8 , which changes on heating into the polymeric *metastyröl*, a colorless transparent solid, identical in composition. The results of W. L. Harrison, confirmed by Maisch (*A. J. P.*, xlv. 160, 165), seem to prove that the American drug is identical with storax, except in containing no water mechanically mixed with it.

Another product is said to be obtained from the same tree by boiling the young branches in water, and skimming off the fluid which rises to the surface. It is of thicker consistence and darker color than the preceding, is nearly opaque, and abounds in impurities. This also has been confounded with liquid storax, which it resembles

in properties, though derived from a different species of Liquidambar. It is said to be used in Texas in coughs. (Gammage, *N. O. M. S. J.*, xii. 636.) For an account of the collection of American storax, see *Ph. Rund.*, 1895, 57.

Liquidambar may be employed for the same purpose as storax, and is so used in the Southern United States, but it is almost unknown in the Northern States. The concrete juice is said to be chewed in the Western States in order to sweeten the breath. The bark of the tree is used with asserted great advantage in the Southern and Western States in *diarrhœa* and *dysentery*, especially in children. It is taken in the form of syrup, which may be prepared from the bark in the same manner as the syrup of wild cherry bark, according to the U. S. Pharmacopœia. The *dose* is a fluidounce (30 Cc.) for an adult, repeated after each stool. (*Am. J. M. S.*, N. S., xxxii. 126.)

Liquidambar Altingia (*Altingia excelsa*), a tree which inhabits a very wide region in Southern Asia, yields a storax-like substance varying in color from white to red. (See *P. J.*, viii. 243.) According to Tschirch and van Itallie, it differs from storax in the presence of benzoic and cinnamic aldehydes, the absence of ether and the small quantities of cinnamic acid in it. The resin of *Liquidambar storesin* is said also to be known in Eastern markets.

Liriodendron. *Liriodendron tulipifera*, L. *Tulip Tree* *Bark*. *American Tulip*. *Poplar Tree*. (Fam. Magnoliaceæ.) *White Tulip Bark*. *Ecorce de Tulipier*, Fr. *Tulpenbaumrinde*, G.—The tulip poplar is a large tree which is abundant in the forests of the Middle United States. Its formerly official bark was taken for use indiscriminately from the root, trunk, and branches, though that of the root is thought to be the most active. Deprived of the epidermis, it is yellowish-white, the bark of the root being somewhat darker than that of the stem or branches. It is very light and brittle, of a feeble, rather disagreeable odor, strongest in the fresh bark, and of a bitter, pungent, and aromatic taste. These properties are weakened by age, and we have found specimens of the bark, long kept in the shops, almost insipid. To the active principle its discoverer, Emmet, gave the name of *liriodendrin*. It is white, crystallizable, brittle, insoluble in water, soluble in alcohol and ether, fusible at 82.2° C. (180° F.), volatilizable and partly decomposed at 132.2° C. (270° F.), of a slightly aromatic odor, and a bitter, warm, pungent taste. It does not unite either with acids or alkalies, and the latter precipitate it from the infusion of the bark by combining with the matter which renders it soluble in water. Water precipitates it from its alcoholic solution. It is obtained by macerating the root in alcohol, boiling the tincture with magnesia until it assumes an olive-green color, then filtering, concentrating by distillation until the liquid becomes turbid, and finally precipitating the liriodendrin by the addition of cold water. (*A. J. P.*, iii. 5.) J. U. Lloyd believes that the active principle is the alkaloid *tulipiferine*, discovered by him in 1886, and this, according to Bartholow, appears to possess toxic properties. (*Ph. Rund.*, 1886, 169.) The virtues of the bark are extracted by water and alcohol, but are injured by long boiling.

Liriodendron is a stimulant tonic, with diaphoretic properties, and has been used in chronic rheumatism and dyspepsia. *Dose* of bark in pow-

der, from half a drachm to two drachms (2.0-7.7 Gm.); of saturated tincture, a fluidrachm (3.75 Co.).

Lithio-mercuric Iodide. $3\text{LiI} + \text{HgI}_2$.—Under the name of *mercuricide*, a compound iodide of the above formula has been brought out as a germicide. It is soluble without decomposition in water, alcohol and ether, and crystallizes in lemon-yellow crystals which are deliquescent. It is alleged that it is as actively germicidal as corrosive sublimate, but is not corrosive, less poisonous and not precipitable by blood serum, albumins or alkalies.

Mercury and Lithium Iodide, or *Hydrargyrum-Lithium Iodatum* of Merck, is a red and granular crystalline powder of the formula $\text{HgI}_2 \cdot 2\text{LiI}$. It is soluble in alcohol or ether, but wholly incompatible with water, forming a cloudy mixture which soon precipitates mercuric iodide. It has been used in Germany as an antisyphilitic, antilithic alterative, and especially in gravel complicated with syphilis.

Lithium Salolo-phosphate. *Lithii Salolo-phosphis.* $\text{C}_6\text{H}_5 \begin{Bmatrix} \text{O}(\text{PO}(\text{OH})(\text{OLi})) \\ \text{COOC}_6\text{H}_5 \end{Bmatrix}$. *Salvosal-Lithia*,

the lithium salt of *saloborlorthophosphorous acid*, is a white crystalline compound, soluble in cold water but decomposed by boiling water with a phenol-like odor. This substance and the allied one known as *salvosal-potash* have been used in doses of four to five grains (0.26-0.32 Gm.) in *influenza* and *gouty conditions*; the half of one per cent. solution has been commended as a mouth wash.

Lithospermum. *Lithospermum officinale*, L. *Gromwell. Miliun Solis*.—A European perennial of the fam. Boraginaceæ, the seeds of which are ovate, of a grayish-white or pearl color, shining, rather larger than millet seeds, and of a stony hardness, from which the generic name of the plant originated. They were formerly used as stimulant diuretics, but are nearly inert.

Lithræa. *Lithræa venenosa*, Miers (*L. caustica*, Hook. and Arn.).—The leaves of this Chilean plant are said to act upon the skin in a manner similar to *Rhus toxicodendron*, and to contain a resin and an ethereal oil. The tincture of the fresh leaves has been used as a counter-irritant.

Litmus. *Lacmus. Turnsole. Tournesol. Lacca Cærulea. Lacca Musica. Laquebleu*, Fr. *Lackmus*, G.—Three purple or blue coloring substances are known in commerce, obtained from lichenous plants. They are called severally *litmus*, *orchil*, and *cudbear*. Litmus is yielded by numerous species of lichens which, under the French name of *orseille*, are brought into commerce from the coasts of Sweden and Norway; from the Alps, the Pyrenees, and other European mountains; from the European and African coasts of the Mediterranean; from the Canaries, Madeira, and various other rocky islands, especially from Mozambique, Madagascar, and Angola, and from California. The species of lichens concerned represent various genera; at present the two most important of the lichens are said to be the *Rocella Montagnei* of Mozambique and the *Dendrographa leucophaea* of California. In the north of Europe *Lecanora tartarea*, Ach., or *Tartarean moss*, and on the Mediterranean coasts the *Rocella tinctoria*, Ach., or *orchilla weed*, at one time furnished the great bulk of the *orseille* of commerce. The chromogenous ethers which constitute the coloring matter of the lichens may be readily detected *in situ* by reagents. (P. J.,

Nov. 10, 1904.) In some of the lichens these coloring principles are chiefly situated in the cortex; in others they are especially abundant in the gonidial layer.

The principles in these plants upon which their valuable properties depend are themselves colorless, and yield coloring substances by the reaction of water, air, and ammonia. They are generally acids or acid anhydrides, and are named *lecanoric*, *orsellio*, *erythric*, etc., according to their origin. *Lecanoric (diorcellinic) acid*, $\text{C}_{16}\text{H}_{14}\text{O}_7$, the original constituent of most of these plants, when boiled with water or alkaline solutions, is changed into *orsellinic acid*, as follows:

Orsellinic acid, $\text{C}_8\text{H}_5 \begin{Bmatrix} \text{CH}_3 \\ (\text{OH})_2, \text{ fuses at } 176^\circ \\ \text{COOH} \end{Bmatrix}$

C. (348.8° F.), and decomposes into *orcin*, $\text{C}_6\text{H}_5(\text{CH}_3)(\text{OH})_2$, and CO_2 . The same decomposition is readily effected by distillation with milk of lime. Orcin combines with ammonia gas to form $\text{C}_6\text{H}_5\text{O}_2 \cdot \text{NH}_3$, the solution of which exposed to the air becomes colored reddish by the formation of *orocin*, $\text{C}_7\text{H}_7\text{NO}_3$. This latter compound forms the basis of the commercial *orseille* extract (*orchil* or *archil*).

Kane (*Watt's Dict.*, vol. iii. 731) described a deep red crystalline substance, *erythrolitmin*, and a brownish-red coloring principle, *azolitmin*, $\text{C}_7\text{H}_7\text{NO}_4$. This latter is considered as the distinctive coloring matter of the commercial litmus. It is nearly insoluble in cold water or benzene, but dissolves in alcohol with red, and in ether with yellow color. It appears to have the characters of a weak acid, the salts of which are blue and the potassium and calcium compounds of which exists in litmus.

To test the value of the plants as dye-stuffs, they may be macerated in a weak solution of ammonia, or a solution of calcium hypochlorite may be added to their alcoholic tincture. In the former case a rich violet-red color is produced; in the latter, a deep blood-red color appears, but soon fades.

Lacmus or *litmus* is prepared chiefly if not exclusively in Holland. The process consists in macerating the coarsely powdered lichens, in wooden vessels under shelter, for several weeks, with occasional agitation, in a mixture of urine, lime and potash or soda. A fermentation ensues, and the mass, becoming first red and ultimately blue, is after the last change, removed, mixed with calcareous or silicious matter to give it consistence, and with indigo to deepen the color, and then introduced into small moulds, where it hardens. It is said that ammonia may be substituted for urine in the manufacture of litmus, but that the reactions necessary for the production of the coloring matter of the litmus are due to the action of the diastase which is found in the lichens. Litmus occurs in rectangular cakes, from a quarter of an inch to an inch in length, light, friable, finely granular, of an indigo-blue or deep violet color, and scattered over with white saline points. It has the combined odor of indigo and violets, tinges the saliva a deep blue, and is somewhat pungent and saline to the taste. From most vegetable blues it differs in not being rendered green by alkalies. It is reddened by acids, and restored to its original blue color by alkalies.

Its chief use in medicine is as a test of acids and alkalies. For this purpose it is employed either in infusion or in the form of litmus paper. The infusion, usually called *tincture of litmus*,

may be made in the proportion of one part of litmus to twenty of distilled water, and two parts of alcohol may be added to preserve it. *Litmus paper* is prepared by first forming a strong clear infusion with one part of litmus to four of water, and dipping slips of white unsized paper into it, or applying it by a brush to one surface only of the paper. The paper should then be carefully dried, and kept in well stoppered vessels, from which the light is excluded. It should have a uniform blue or slightly purple color, neither very light nor very dark. As a test for alkalies the paper may be stained with an infusion of litmus previously reddened by an acid, care being taken to avoid all excess. By gas light it is said that the change of color cannot be determined by the eye exactly, as the blue of litmus becomes mauve; but this may be obviated by watching the process through a green glass, by which the faintest trace of blue becomes discernible. (*P. J.*, 2d ser., vi. 479.) For the official method of preparing litmus paper, see Tests, Test solutions, etc., PART III.

Orchil, or *archil*, as prepared in England, is in the form of a thickish liquid, of a deep reddish-purple color, but varying in the tint, being in one variety redder than in another. The odor is ammoniacal. It is made by macerating lichens in a covered wooden vessel, with an ammoniacal liquor, either consisting of stale urine and lime, or prepared by distilling an impure salt of ammonia with lime and water. (Pereira.) For details as to the method of preparation, see *Chem. News*, 1874, 143. It is occasionally adulterated with the extracts of colored woods, as logwood, sappan-wood, etc. A mode of detecting these adulterations is given by F. Leeshing in the *Chem. Gaz.* of June 1, 1855, 219.

Cudbear (*Orseille de terre*, Fr.; *Persio*, G.) is in the form of a purplish-red powder. It is procured in the same manner as orchil; but the mixture, after the development of the color, is dried and pulverized.

The point in which the preparation of these coloring substances differs from that of litmus appears to be, that potassium or sodium hydroxide is added, in the latter, to the ammoniacal liquid used. Orchil and cudbear are employed as dye-stuffs, and sometimes, in like manner with litmus, as a test of acids and alkalies. For some practical applications, see *A. J. P.*, 1874. For chemical constituents of lichens, see *A. J. P.*, 1898, 455.

Loco Plants. *Crazy Weeds*.—These are plants growing in the far Western States, the eating of which by horses and cattle is believed to produce loss of flesh, disordered vision, delirium, convulsive movements, or stupor and death. It has been claimed that *Astragalus mollissimus*, Torr., is the loco of Kansas, while *A. Drummondii*, Dougl., is the loco plant of Colorado.

In conformity with this Isaac Ott found a plant, which he believed to be *A. mollissimus*, to act as a violent spinal poison and mydriatic (*N. R.*, Aug. 1882), and, according to Carl Ruedi, the decoction produces in the rabbit great hilarity, excitement, and even ferocity, and contains an alkaloid, *locoine*, and an acid. (*Tr. Col. State Med. Soc.*, 1895.) On the other hand, O'Brien, of the State Agricultural College of Colorado, was not able to obtain any active chemical substance from six U. S. species of the genus, including the two previously mentioned, while in a very careful study of a plant which was neither in flower nor in seed, but whose identifi-

cation as *A. mollissimus* was clear, H. C. Wood found that it was not poisonous to rabbits or dogs, a result which has been confirmed by James Kennedy, *Ph. Rec.*, July, 1888; by Ingersoll, *Proc. A. Ph. A.*, 1890; and by L. E. Sayre, *Proc. A. Ph. A.*, 1888. This also is in accord with the researches of O'Brien (*Bulletin* 25, *Agricultural Experiment Station of Colorado*), and it would appear that *A. mollissimus* is not a poisonous plant. Other species of the genus, especially *A. Hornii*, A. Gray, *A. Bigelovii*, A. Gray, and *A. crassicaupus*, Nutt. (*A. caryocarpus*, Ker.) have had poisonous properties attributed to them, and in the fruit of the last-mentioned species G. B. Frankforter believes he has demonstrated the presence of an alkaloid. There can be no doubt that domestic animals are destroyed in the West in very large numbers from an affection which is known as "loco," and hundreds of thousands of dollars have been spent in bounties by the State of Colorado for the extirpation of the supposed poisonous *astragalus*. It is probable that many of the deaths attributed to loco have been from other causes. Thus, Ingersoll of the Colorado State Agricultural College, found in a large number of loocoed sheep masses of *Tania expansa*, which he believed to be the cause of death. It is a probable explanation that the phenomena of loco disease are due to the fermentation of an *astragalus* or other plant in the intestines of the animals, and the production of one or more poisons which are absorbed and produce narcotic symptoms. If this be correct the loco disease is parallel in its etiology and nature to the lathyrismus of Europe. See *Lathyrus sativus*; also N. Y. M. J., 1889, xlix. Similar effects are produced in horses by the pods of the mesquite (*Prosopis juliflora*, Swz., DC.), when eaten too freely. According to Haeckel (*Die naturlichen Pflanzen Familien*), the Russian grass *Stipa capillata* frequently kills sheep, not, however, by a direct poisonous action, but by its glumes working through the skin into the vital organs; and *Stipa viridula*, Trin., which is said in some parts of New Mexico and Texas to be known by the name of "sleepy grass," is believed by some ranchers to be the cause of loco disease. In the experiments of A. Lockhart Gillespie (*B. M. J.*, ii. 1898) the extract of this grass was found to act upon rabbits and frogs as an active poison, especially affecting the nerve centres but also influencing the heart.

Lolium. *Lolium temulentum*, L. Darnel. Bearded Darnel. *Ivraie*, Fr. *Lolch*, *Taumelkorn*, G. This grass, which has spread over the world wherever wheat is cultivated, owes its importance to its growing especially with wheat, so that its ground seeds are eaten in the flour. From ancient times its seeds have been believed to produce an intoxication similar to that of alcohol; hence its specific Latin name and the French name, *Ivraie*. In the sweetish seeds, P. Antze (*A. J. P.*, 1891, 568) believed that he found a solid alkaloid, *temulentine*, and a volatile one, *loliine*; but Hofmeister (*A. J. P.*, 1892, 611) determined that the volatile alkaloid was an impure ammonia, while the temulentine was a mixture which contained a nitrogenous acid and an uncrystallizable alkaloid, *temuline*, of which the hydrochloride has the formula $C_7H_{12}N_2O \cdot 2HCl$.

It is alleged that *lolium* seeds produce vertigo, dizziness, headache, somnolence, and general intoxication in man, as well as in dogs, sheep and horses, while they are innocuous to hogs, cows,

and poultry. Rivière and Maizière (*J. P. C.*, 1863, 280) have recorded death as occurring from the use of bread containing large amounts of darnel. P. Antze found that both *loline* and *temulentine* are poisonous, causing violent gastro-intestinal irritation, dyspnea, and general depression. (*Cb. G. T.*, 1891.) M. P. Guérin believes the poisonous properties of darnel are due to the presence of a fungus. (*Morots Journ. de Bot.*, 1898.)

Lonchocarpus. *Lonchocarpus violaceus*. *Stinkwood*.—The wood of this papilionaceous tree is said to be used by the natives of Surinam as a fish poison. (*Ph. Cb.*, xxxix, 282.)

Lonicera. *Lonicera Caprifolium*, *L. Honey-suckle*. (Fam. Caprifoliaceæ).—The flowers of the common honeysuckle are sometimes used in perfumery, and a syrup of the fruit has been commended in *asthma*. The fruit of all the species of *Lonicera* is said to be emetic and cathartic (Mérat and De Lens), and that of *L. xylosteum* (L.) to have caused serious poisoning. (*J. P. C.*, 4e sér., xviii, 65.)

Loretin. *Meta-iodo-ortho-oxyquinoline-ana-sulphonic Acid*. $C_9H_4IN.OH.SO_3H$.—This organic iodine compound, discovered by Claus of Freiburg, contains 36.2 per cent. of iodine and is a bright yellow, odorless, crystalline powder, insoluble in ether and oils, soluble in 500 to 1000 parts of cold water, and in 167 to 200 parts of boiling water; it forms neutral soluble salts with sodium, potassium, ammonium, and magnesium, yielding deep orange-yellow solutions. It is very stable for an iodine compound, not being affected by exposure to direct sunlight. It was found by Ammelburg to be much more powerful as a germicide than iodoform, with seven different pathogenetic germs assayed. Given hypodermically to guinea pigs (5 Cc. of a 5 per cent. solution for long periods), it produced no poisoning, and no iodine could be detected in the urine. (*Deutsche Zeitsch. für Ther. Med. und Vergleich. Path.*, 1894.)

It has been especially commended as a substitute for iodoform by Schinsinger and by Snow. (*B. M. J.*, ii, 1895.) It may be used as a dusting powder alone or mixed with calcined magnesia or starch; as collodion, from 2 to 10 per cent.; as ointment, 5 to 10 per cent.; and in solution, 1 to 2 per cent. of the soluble sodium salt. The soluble calcium salt, *calcium loretin*, has been especially recommended for the manufacture of antiseptic gauze. Snow states that the pure powder may be used without danger of poisoning or of local irritation.

Lotus. *Lotus arabicus*.—According to W. R. Dunstan and T. A. Henry, the leaves of this leguminous plant contain a yellow crystalline glucoside, *lotusin*, $C_{22}H_{19}NO_{10}$, and an enzyme, *lotase*, by which lotusin is converted into prussic acid and a yellow substance, *lotoflavin*. (*Proc. Roy. Soc.*, 67, 224.)

Lucuma.—This Brazilian genus of the fam. Sapotaceæ yields a number of species, which are used in Brazil as medicines or articles of diet. For an account of them, see *Ph. Rund.*, 1888. See also *Monesia*.

Luffa. *Luffa ægyptiaca*. *Vegetable Sponge*. *Wash-rag Sponge*. *Gourd Towel*.—A cucurbitaceous genus, indigenous to Arabia and Egypt, furnishing a gourd-like fruit, which presents upon the removal of the epidermis a durable skeleton of interwoven woody fibres, which are used in place of sponge. Reinhard J. Weber has furnished the following description of *Luffa ægyptiaca*

as grown in this country: It is a large climbing vine, with a thin but very tough light green, succulent stem, attaining a length of from 10 to 30 feet. The leaves are alternate and palmately-lobed, of a light green color, and almost destitute of taste. The flowers are monœcious, petals five, united below into a bell-shaped corolla; anthers cohering in a mass; ovary two-celled, style slender, stigmas three. The fruit is elliptical-ovate, fleshy and dehiscent, with a green epidermis, longitudinally marked with black lines, varying from ten to fifteen in number; under each of these lines is found a tough, woody fibre. The seeds are numerous and almost flat, broadly-ovate, three-eighths of an inch long. (*A. J. P.*, 1884, 6.) The fruit of *L. echinata*, Roxb., of India, is a violent irritant poison, from which C. J. H. Warden has separated a principle allied to, if not identical with, *colocynthisin*. (*P. J.*, June, 1890.)

Lupinus. *Lupinus albus*, *L. Lupin*. *Lupin*, Fr. *Feigbohne*, *Wolfsbohne*, G.—A plant belonging to the Leguminosæ, and a native of Europe and Western Asia, which is sometimes cultivated in our gardens. Other species are also met with,—*L. hirsutus*, L., *L. luteus*, L., *L. polyphyllus*, Lindl., *L. densiflorus*, Benth. The last two are indigenous to the Pacific slope and the West. The bitter principle *lupinin*, $C_{25}H_{32}O_{16}$, is a glucoside, and its solution in alkalies is of a dark brownish-yellow color. On boiling with dilute acids it is decomposed into *lupigenin*, $C_{17}H_{12}O_6$, and a fermentable, dextro-rotatory glucose. The bruised seeds of white lupin, after soaking in water, are sometimes used as an external application to *ulcers*, etc., and internally are said to be anthelmintic, diuretic, and emmenagogue. An instance has been recorded where a decoction used as an injection in the rectum caused symptoms which suggested a poisonous character for the drug. Schulze and Steiger have isolated an alkaloid, *arginine*, $C_6H_{14}N_4O_8$, from the germinated seeds of *Lupinus luteus*. (*A. J. P.*, 1887, 428.) Steiger (*J. Soc. Chem. Ind.*, 1886, 385) has also studied a carbohydrate analogous to dextrin, which Baeyer and Eichborn discovered in *Lupinus luteus*. He finds that it is not changed by yeast, that nitric acid converts it into mucic acid, and that diluted sulphuric or hydrochloric acid converts it into galactose.

Lycetol. *Dimethylpiperazine Tartrate*. $NH(CH_2CHCH_3)_2NH + H_2C_4H_4O_6$.—This is the tartrate of a substitution product from piperazine, in which an atom of hydrogen in each of two CH_2 groups is replaced by the methyl group CH_3 . Lycetol is a white powder melting at $250^\circ C.$ ($482^\circ F.$), readily soluble in water, having a taste which is described as pleasant and acidulous. It is asserted that it is an active diuretic, exerting a powerful solvent influence upon uric acid, and causing no disturbance of digestion even when given continually in large doses. According to Hamonic, it acts very favorably in purulent *cystitis*, lessening suppuration and the tendency to decomposition of the urine. It has been used with asserted excellent results in *chronic* and *acute* *gout*, and in various other forms of *uric acid diathesis*, as well as for solution of *calculi*. Dose, of lycetol, from fifteen to thirty grains (1.0–2.0 Gm.) daily, administered in from one to two pints of water.

Lycium. *Lycium vulgare* (Ait. f.), Dunal (*L. barbarum*, var. *vulgare*, Ait. f.). *Matrimony Vine*. The genus *Lycium* belongs to the Solanaceæ. Different species have been used in various parts of

the world for supposed medicinal virtues. *Lycium vulgare*, which is indigenous in the south of Europe and in Asia, is a thorny shrub, with long flexible branches, and is cultivated for hedges and arbors. Husemann and Marmé found in the leaves and stem an alkaloid, *lycine*, $C_5H_{11}NO_2$. (A. J. P., 1864, 226.) It is characterized by its strong affinity for water, which causes it to deliquesce in a few minutes after exposure, and renders it very soluble in that liquid. It is also readily soluble in alcohol, but nearly insoluble in ether. It is crystallizable, of a sharp but not bitter taste, and forms crystallizable salts with the acids. Aug. Husemann believes that lycine does not exist in the plant, but is formed during the process of extraction, and also that it is identical with *betaine*, $C_5H_{11}NO_2$, the alkaloid obtained from beet juice by Scheibler, and with the oxynurine of Liebreich. (A. J. P., xlvii. 209.) E. Schmidt found in *Lycium vulgare* traces of mydriatic alkaloids, resembling those of belladonna. (Ap. Ztg., 1890, 511.) The young shoots of one of the species of *Lycium* are eaten in Spain as asparagus, and its leaves as salad, and the aborigines of Colombia used another species against *erysipelas*. The leaves of *L. vulgare*, as well as the fruit, are said to be used by the physicians of Japan. (Mérat and De Lens.)

Lycocetona.—For its physiological action, see P. M. T., Oct. 1875.

Lycopodium Saururus, Lam. *Piligan*.—In this Brazilian lycopod Adrian has found an actively poisonous alkaloid, *piliganine* (C. R. A. S., June, 1886). (See also B. G. T., cxi. 174.)

Lycopus. U. S. 1870. *Lycopus virginicus*, L. *Lycopo de Virginie*, Fr. *Virginischer Wolfssuss*, G.—The bugle-weed is a labiate which grows throughout the greater part of the Eastern United States. Its flowering period is August. The whole herb is used. Jos. L. Weil found 0.41 per cent. of a fat melting at 50° C. (122° F.), 0.68 per cent. of a granular wax melting at 70° C. (158° F.), 0.43 per cent. of a crystallizable resin soluble in ether, a crystallizable glucoside, and a small quantity of gallic acid and tannin. (A. J. P., 1890, 72.) It has a peculiar odor and a nauseous slightly bitter taste, and imparts these properties, as well as its medicinal virtues, to boiling water.

Lycopus europæus, L., is said to be frequently collected and sold for *L. virginicus*. The former may be distinguished by its acutely quadrangular stem, its narrow lanceolate leaves, of which the lower are somewhat pinnatifid, its more crowded flowers, and the acute segments of its calyx, armed with short spines. It has been employed in Europe as a substitute for quinine.

According to A. W. Ives, the bugle-weed is a mild narcotic and an astringent, useful in pulmonary and other hemorrhages. Dose of decoction, (one ounce to one pint of boiling water), from half a pint to one pint (240–480 Cc.) daily.

Lycoris. *Lycoris Radiati*. (Fam. Amaryllidaceæ).—According to Morishima (A. E. P. P., 40) this plant contains two alkaloids, *lycorine*, $C_{32}H_{32}N_2O_8$, which occurs in large colorless polyhedral crystals, and is physiologically very active; and *sekisanine*, $C_{34}H_{34}N_2O_8$ which occurs in colorless, anhydrous columns and is quite inactive physiologically.

Lygosin. *Di-ortho-cumar-ketone*.—The sodium salt is a ruby-red compound readily soluble in water; the quinine salt is an amorphous orange-yellow powder. According to Aujezki, sodium lyg-

osinate is very feebly bactericidal, and is capable of lowering the temperature in fevered rabbits. Filep asserts that the *quinine lygosinate* is actively bactericidal and suggests its use in the treatment of wounds.

Lysidine.—Lysidine is a reddish-white, crystalline substance, melting at 105° C. (221° F.), readily soluble in water and alcohol and having a peculiar nauseous taste suggesting the odor of mice. On account of its great hygroscopicity it is now supplied to the trade in a uniform 50 per cent. solution. It was brought forward by Ladenburg as a solvent for *uric acid*, with the statement that it had five times the power of piperazine. See also Grawitz (D. M. W., 1894) and Woodcock Goodbody (B. M. J., ii. 1896). Goodbody believes that lysidine is more active as a diuretic than is piperazine. We have used it in our cases with apparent good results. Dose, ten to twenty grains (0.65–1.3 Gm.) may be given three times a day in a half pint of aerated water.

Lysiform is an alcoholic potash soap containing formaldehyde. This preparation of formic aldehyde resembles in its general appearance glycerin, is miscible in water in all proportions, but should not be heated above 37.7° C. (100° F.) lest the formic aldehyde be volatilized. Diluted with its own bulk of water it forms a lather, and is useful for skin disinfection. Its 5 per cent. solution is said to be effectively germicidal, and it is stated not to be irritating either to the skin or to the mucous membrane. According to the researches of Franz Nagelschmidt (Th. M., 1902) it is about three times less poisonous to rabbits than is lysol.

Lysiform may be used as an antiseptic mouth or nose wash, one to three teaspoonfuls to a pint; as a vaginal or uterine douche, from four to six teaspoonfuls to a pint; for abscess cavities, suppurating sinuses, etc., six teaspoonfuls to the pint or stronger; for disinfecting the hands or instruments, six to twelve fluidrachms to the pint.

Carbollysiform, so-called, is said to be a 3 per cent. solution of phenol in lysiform.

Lysulfol.—A black unguentous mass said to contain lysol with 10 per cent. of sulphur. It is entirely soluble in water and is highly commended by E. Rumpf in *pityriasis versicolor*, *scabies*, *acne*, *psoriasis* and *prurigo*, well rubbed in on the part, in the evening and thoroughly washed off in the morning.

Lythrum. *L. Salicaria*, L. *Loosestrife*. *Purple Willow-herb*. *Salicaire*, Fr. *Röther Weiderich*, G.—This is an elegant perennial plant of the fam. Lythraceæ, a native of Europe, but naturalized from Ontario to Kentucky and Arkansas. The dried herb is inodorous, and has an herbaceous, somewhat astringent taste. It has been used as a demulcent astringent in *diarrhœa* and chronic *dysentery*, especially in Ireland and in Sweden. The dose of the powdered herb is about a drachm two or three times a day. A decoction of the root, prepared by boiling an ounce in a pint of water, may be given in the dose of two fluid-ounces (60 Cc.).

Macallo or Yaba Bark.—For an article on this Yucatan bark, see A. J. P., 1879, 392.

Mackay Bean.—This is the seed of *Entada scandens*, Benth. (Fam. Leguminosæ), of Queensland, which has the reputation in the colony of being strongly poisonous, and in which John Moss found saponin. (P. J., vol. xviii. 242.)

Magnesium Acetate. *Magnesiæ Acetas*. Mg ($C_2H_3O_2$)₂·4H₂O.—This salt has been used as a

substitute for the citrate, but is much inferior. For further information, see previous editions, *U. S. D.*

Magnesium Benzoate. *Magnesi Benzoas. Benzoate de Magnésie, Fr. Magnesiumbenzoat, G.* $\text{Mg}(\text{C}_7\text{H}_5\text{O}_2)_2 + 3\text{H}_2\text{O}$.—Made by neutralizing a hot solution of benzoic acid with magnesium carbonate and crystallizing. A white, crystalline powder, permanent in the air, soluble in 20 parts of water or alcohol. Used for *gout, urinary calculi, and tuberculosis*, in doses of from three to fifteen grains (0.2–1.0 Gm.).

Magnesium Bromide. *Magnesi Bromidum. Bromure de Magnésie, Fr. Magnesiumbromid, G.* $\text{MgBr}_2 + 6\text{H}_2\text{O}$.—Made by neutralizing hydrobromic acid with magnesium oxide, evaporating and crystallizing. In the form of colorless, very deliquescent crystals, used as a nerve, in doses of from five to thirty grains (0.32–2.0 Gm.).

Magnesium Chlorate. *Magnesi Chloras. Mg(ClO₃)₂*.—This salt in 20 per cent. ointment has been highly commended (*S. M.*, 1899) by Herscher and Gaucher in the treatment of *epithelioma*.

Magnesium Chloride. *Magnesi Chloridum. MgCl₂*.—This is produced at Stassfurt in the potash and bromine industries. When a concentrated solution of this salt is evaporated to dryness, it is partially decomposed into magnesium oxide and hydrochloric acid, the latter being evolved. By a careful evaporation, stopping it so soon as the vapor begins to redden litmus paper, the chloride may be obtained in the state of a fused hydrate, having the composition $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$. Or, by adding ammonium chloride to the solution, the mixed chlorides can be evaporated to dryness, and the sal-ammoniac volatilized without decomposing the magnesium chloride. Lebert found this bitter and very deliquescent salt to act mildly and favorably as a purgative, producing a flow of bile and an increase of appetite. On account of its extreme deliquescence, he recommended it in the liquid form, prepared by dissolving the salt in its weight of water. *Dose*, for an adult, an ounce (31 Gm.) sufficiently diluted, and half an ounce (15.5 Gm.) to a child ten years old. (*A. G. M.*, 4e sér., iii. 448.)

Magnesium Dioxide. *Magnesi Dioxidum. Biogen*.—This dioxide is an odorless white powder, insoluble in water, alcohol, or ether, which like hydrogen dioxide, readily yields up one atom of oxygen. Magnesium dioxide probably has some influence as an intestinal antiseptic, but beyond this it is not probable that it has any therapeutic value; ten to forty grains (0.65–2.6 Gm.) may be given at the *dose*.

Magnesium Lactate. *Magnesi Lactas. Lactate de Magnésie, Fr. Magnesiumlactat, Milchsäure Magnesia, G.* $\text{Mg}(\text{C}_3\text{H}_5\text{O}_3)_2 + 3\text{H}_2\text{O}$.—The salt is made by double decomposition between 6 parts of calcium lactate and 5 parts of magnesium sulphate, or by neutralizing diluted lactic acid with magnesium carbonate and evaporating to dryness. In white granular crystals, soluble in about 30 parts of cold water and 6 parts of boiling water, insoluble in alcohol. Used as a mild laxative in doses of from fifteen to forty-five grains (1–3 Gm.).

Magnesium Salicylate. *Magnesi Salicylas. Mg(C₆H₄(OH)CO₂)₂ · 4H₂O*.—This salt has been enthusiastically recommended by Huchard in *typhoid fever*, given in daily doses of from fifty to one hundred grains (3.2–6.5 Gm.) continuously; diarrhoea is not a contraindication to its

use. According to B. Fischer (*Ph. Ztg.*, 1888, 146), the salt is prepared by dissolving salicylic acid in boiling water, saturating the solution with magnesium carbonate, filtering, and crystallizing. It forms long, colorless hygroscopic needles, which are readily soluble in water and alcohol, and have a somewhat bitter taste. (*A. J. P.*, 1888.)

Magnesium Silicate. *Hydrated Magnesium Silicate. Meerschäum. H₂Mg₂Si₂O₉ + H₂O*.—Meerschäum is one of several hydrated silicates of magnesium, talc and serpentine being others of analogous formula. It is used for the manufacture of tobacco pipes. It was brought into notice as a medicine by Garraud, who used it successfully as a substitute for bismuth subnitrate in obstinate *diarrhoea*. Trouseau employed it also with great success in numerous cases of diarrhoea. It no doubt acts mechanically, either as an absorbent or a protective of the intestinal coats. (*J. P. C.*, 4e sér., iii. 385.) It should be reduced to a very fine powder, and given in doses of from one to four drachms (3.9–15.5 Gm.) a day.

Magnesium Sulphite. *Magnesi Sulphis. U. S. 1880. MgSO₃ · 6H₂O*.—This salt may be prepared by double decomposition between magnesium sulphate and neutral sodium sulphite. Owing to the almost universal presence of sulphate in the sodium sulphite, Jos. P. Remington proposes to prepare it by suspending eight parts of pure magnesia in sixteen parts of water, and then adding gradually, with stirring, official aqueous sulphurous acid in excess. The crystals which form are washed with very cold water, drained, and dried. (*A. J. P.*, xl. 97.) "A white, crystalline powder, gradually becoming oxidized on exposure to air, odorless, having a slightly bitter, somewhat sulphurous taste, and a neutral or slightly alkaline reaction. Soluble in twenty parts of water at 15° C. (59° F.), and in nineteen parts of boiling water; insoluble in alcohol. When heated to 200° C. (392° F.), the salt loses its water of crystallization (50.9 per cent.), and is converted into magnesium oxide and anhydrous magnesium sulphate. The aqueous solution of the salt, mixed with ammonium chloride, yields, with excess of test-solution of sodium phosphate and water of ammonia, a white, crystalline precipitate soluble in acids. When treated with four times its weight of diluted hydrochloric acid, the salt dissolves completely and emits the odor of burning sulphur, without becoming cloudy (difference from hyposulphite). A 1 per cent. aqueous solution, strongly acidulated with hydrochloric acid, should not afford more than a slight cloudiness with test-solution of chloride of barium (limit of sulphate)." Magnesium sulphite shares the general medicinal properties of the sulphites, but is better fitted for internal administration on account of its less solubility and less disagreeable taste, etc. (See *Sodii Sulphis*.) The *dose* is from fifteen grains to half a drachm (1–2 Gm.).

Magnolia. *U. S. 1880. Magnolia Bark. Ecorce de Magnolier, Fr. Magnolienrinde, G. (Fam. Magnoliaceae)*.—Three species of magnolia were formerly official, as follows: 1. *Magnolia virginiana*, L. (*M. glauca*, L.), which in the Northern States is often nothing more than a shrub, sometimes attains in the South the height of forty feet.

M. virginiana is found along the seaboard of the United States, from Cape Ann, in Massachusetts, to the shores of the Gulf of Mexico. It is usually

known as *magnolia* in the North, and as *white bay* or *sweet bay* in the South, but is occasionally called *swamp sassafras*, *beaver-tree*, etc.

2.—*M. acuminata*, L. *Cucumber-tree*. Grows to the height of seventy or eighty feet.

3.—*M. tripetala*, L., is a small tree, sometimes, though rarely, attaining a height of thirty feet. It extends from Northern New York to the southern limits of the United States. Wallace Procter found in the fruit a neutral crystalline principle, *magnolin*. When pure, this is without odor and has at first little taste, in consequence of its insolubility in the liquids of the mouth, but after a time produces an irritant effect on the fauces. It is nearly insoluble in cold, but slightly soluble in hot water, very soluble in alcohol, ether, chloroform, carbon disulphide, and benzine. Procter considered it analogous to the liriodendrin obtained by Emmet, but quite distinct. *Magnolin* has also been obtained by Stephen Procter (*A. J. P.*, xiv. 95) from the bark of *M. foetida* (L.), Sarg. (*M. grandiflora*, L.), and by W. D. Harrison from that of *M. glauca*. (*A. J. P.*, xxxiv. 29.) For a more detailed account of it, see *A. J. P.*, 1872, 145; also Lloyd's paper in *Ph. Rund.*, 1866, 224. W. F. Rawlins (*A. J. P.*, 1889, 7) obtained from the leaves of *M. glauca* a small quantity of a volatile oil of bright green color, with an odor resembling fennel or anise, but more pleasant. From the ethereal solution of this oil small crystals deposited. Indications were also obtained of a bitter glucosidal principle.

The bark and fruit of all the species of *Magnolia* are possessed of similar medicinal properties; but the bark only was official, and that of the root has been thought to be most efficient. "The bark from young wood is quilled or curved, thin, externally orange-brown and glossy, or light gray, with scattered warts and somewhat fissured, internally whitish or pale brownish and smooth; fracture short, in the inner layer somewhat fibrous; inodorous; taste somewhat astringent, pungent, and bitter. The bark of old wood, deprived of the cork, is whitish or brownish, fibrous, and less pungent." *U. S.* 1880. The aromatic property, which resides in a volatile principle, is diminished by desiccation, and entirely lost when the bark is long kept. The bitterness, however, remains. The bark is destitute of astringency.

Magnolia is a gently stimulant aromatic tonic and diaphoretic. It has been used in *malaria* and in *rheumatism*. The dose of the recently dried bark in powder is from half a drachm to a drachm (2.0-3.9 Gm.), frequently repeated. Diluted alcohol extracts all the virtues of the medicine, and a tincture, made by macerating the fresh bark or fruit in brandy, is a popular remedy in chronic rheumatism.

Malakin. *Salicyliden-paraphenetidin*. $C_6H_4 \{ OC_2H_5 \}$
 $\{ N: CH.C_6H_4(OH) \}$.—This occurs in small, bright yellow, fine needles, melting at 92° C. (197.6° F.), insoluble in water, sparingly soluble in cold, but quite so in hot alcohol, insoluble in carbonates of the alkalis, but soluble with a yellow color in soda lye; weak mineral acids decompose it, forming salicylaldehyde and paraphenetidin.

Malakin contains about 50 per cent. of salicylaldehyde, and in 1893 Jacquet called attention to it as an anti-rheumatic remedy, stating that it is decomposed in the stomach, yielding salicylaldehyde to the blood, and offering, therefore, a

method of giving salicylic acid. Cases have been reported not only by Jacquet, but by Merkel, by Korotkoff, by Oussoff, by Abernethy, and others, in which, in doses of from forty-five to ninety grains (3.0-5.8 Gm.) a day, malakin acted very favorably in *acute rheumatism*. On the other hand, Ottolenghi (*Ther. Woch.*, ii. 1895) has found that after the administration of malakin, crystals of it can be found throughout the whole intestines, even as low as the rectum, so that the decomposition and after-absorption of it must be exceedingly slow and uncertain, and the contention of Bauer, that it is distinctly inferior to the older salicylates, is in all probability correct. Ottolenghi suggests that malakin must act on tænia and other intestinal parasites, and may therefore prove useful as an anthelmintic.

Malambo or Matias Bark.—A bark received from South America by Alex. Ure, under the name of *matias bark*, was found to have the characters of the *malambo bark*, which is held in high esteem in Colombia, where it is produced. According to H. Karsten, it is derived from a hitherto undescribed species of *Croton*, which he names *Croton Malambo*. (See *Flora Colombiae Terrarumque adjacentium Specimina Selecta*.) This is a small tree or shrub, growing on the coast of Venezuela and Colombia. (*P. J.*, 1859, 321.) The bark is described by Ure as being three or four lines thick, brittle, though somewhat fibrous, of a brown color, and covered with an ash-colored tuberculous epidermis. It has an aromatic odor and a bitter pungent taste, and yields these properties to water and alcohol. Its active ingredients appear to be a volatile oil and a bitter extractive matter. According to Mackay, it has been used successfully in *intermittents*, *convalescence* from continued fevers, *hemicrania*, *dyspepsia*, and other cases in which tonic remedies are useful, and also as an adjuvant to diuretics. It is probably nothing more than an aromatic tonic. Ure has administered it with good effect as a substitute for Peruvian bark. (*P. J.*, iii. 169.)

Under the name of *Winter's bark*, a considerable quantity of bark was some time since imported into the United States from South America, which E. S. Wayne of Cincinnati, has identified with the *malambo bark* above described, having found it to correspond with that product both in sensible characters and composition. (*A. J. P.*, xxix. 1.) George B. Wood confirmed this decision of Wayne; a specimen in his possession answered precisely to the description given by Ure. The *malambo bark*, analyzed by Cadet de Gassicourt, yielded volatile oil, bitter resin, and extractive, but no tannic or gallic acid, and no alkaloid, and the same was the case with the so-called *Winter's bark* examined by Wayne. (*Ibid.*) The same bark has been analyzed by F. B. Daney, who found in it volatile oil, gum, starch, albumen, resin, extractive, fixed oil, wax, and several inorganic substances. (*Ibid.*, 219.)

Malarin.—This is a yellowish-white powder, insoluble in cold water, which is said to be a condensation product obtained by heating molecular equivalents of acetophenone and paramidophenetol. It has been suggested for use as an antipyretic.

Malouetia. *Malouetia nitida*, Spruce. *Gauchamaced.* (Fam. Apocynaceæ).—This plant, of Venezuela, contains an alkaloid, *guachamacine*, which Kobert believes to be identical with *curarine*. (*A. J. P.*, 1885, 560.)

Malva. *Malva sylvestris*, L. *Common Mallow*. *Flores Malvæ, Folia Malvæ*, P. G. *High Mallow*. *Mauve Sauvage, Grande Mauve*, Fr. *Käsepappel, Waldmalve*, G.—This is a perennial, herbaceous European plant of the fam. Malvaceæ. Almost all the species of the genus are possessed of the same properties. *M. rotundifolia*, L., one of the most common, may be substituted for *M. sylvestris*. The herb and flowers have a weak, herbaceous, slimy taste, without odor. They abound in mucilage, which they readily impart to water, and the solution is precipitated by lead acetate. The infusion and tincture of the flowers are blue, and serve as a test of acids and alkalies, being reddened by the former and rendered green by the latter. The roots and seeds also are mucilaginous. Common mallow is emollient and demulcent. The infusion and decoction are sometimes employed in *catarrh, dysentery*, and *nephritic complaints*, and are applicable to all other cases which call for the use of mucilaginous liquids.

Manaca.—This is a portion of the root and stem of *Brunfelsia hopeana*, Benth. (*Franciscæ uniflora*, Pohl.), a Brazilian plant belonging to the fam. Solanaceæ. It occurs in pieces from a few inches to one foot in length, and about one-half inch in diameter, very tough and woody, with a yellowish centre and a dark, very thin outer bark. The stem portion has a very small yellowish pith. H. B. Parsons (*Am. Chem. J.*, vol. i. No. 6) came to the conclusion that it contains no alkaloid, but R. Lenardson (*In. Dis.*, Dorpat, 1884) asserts that he has found in it an alkaloid, *manacine*, besides a peculiar fluorescent substance supposed to be identical with *gelseminic acid*. *Manacine* is described as a light yellow, very hygroscopic powder, of a faint bitter taste, possessing very feeble basic properties, melting at 115° F., freely soluble in water and ethyl and methyl alcohol, but insoluble in ether, benzene, amyl alcohol, and chloroform. E. P. Bruer (*T. G.*, 1882), as the result of experiments made upon the lower animals, arrived at the conclusion that manaca acts upon the spinal cord, first stimulating, and then abolishing the activity of the motor centres, the action being shared in by the respiratory centres. All the glands, especially the kidneys, were stimulated by it. In large doses he found it to produce in man lassitude, perspiration, and loose, greenish alvine discharges. *Manaca* has been very strongly recommended in the treatment of chronic or subacute *rheumatism* and *syphilis*. The dose of the fluidextract is from ten to thirty minims (0.6–1.8 Cc.) three times a day. (See *T. G.*, 1880; also New Series, vols. ii. and iii.)

Mandragora. *Mandragora officinarum*, L. *Atropa Mandragora*, L. *Mandrake*. *Mandragora*, *Mandragore*, Fr. *Alraunwurzel*, G.—A perennial European plant, with spindle-shaped root, which is often forked beneath, and is therefore compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, and was used as an amulet to promote fecundity, etc., and the superstition is still cherished by the vulgar in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. Crouzel isolated an alkaloid, *mandragorine*, which he found similar in properties to atropine. (P. J., 1885, 1067.) It has since been more thoroughly studied by F. B. Ahrens. (*Ber. d. Chem. Ges.*, 1889, 2159–2161.) *Mandragorine* is colorless, inodorous, deliquescent, melts at from

77° to 79° C. (170.6°–174.2° F.), and has the formula $C_{17}H_{23}NO_3$. It seems to be isomeric with atropine, but is not converted into it by alkalies. The sulphate and the hydrochloride are crystalline and deliquescent. A second alkaloid in much smaller amount was also extracted, of which the gold and platinum double chlorides were formed. Both alkaloids had a mydriatic action. It was much used by the ancients as a narcotic, and as an anæsthetic agent before surgical operations. (J. P. C., xv. 290.) *Morion* or *death-wine*, said to have been administered previous to the torture, was made from it. Its physiological action has been partially investigated by B. W. Richardson. (*B. F. M. R.*, 1874, 242.)

Manganese. *Manganum*.—This metal and its compounds with oxygen have been described. (See *Mangani Dioxidum Præcipitatum*, p. 759.) Several of its salts have been proposed as medicines, to be used as tonic and anti-æmic remedies. Manganese as well as iron is always present, in minute proportion, in healthy blood, and has been detected in various solids and fluids of the body. According to an analysis by Burin-Dubuisson, the amount of manganese in the blood corpuscles is about one-twentieth that of the iron. It is stated, as an advantage of the preparations of manganese, that they may be prescribed in conjunction with tannic acid and the various astringent medicines, which are all incompatible with the preparations of iron. Of the manganous oxides, the *monoxide* only is strongly salifiable, and this is the oxide present in the ordinary salts of the metal. It may be obtained by precipitation, as a white hydrate, from any of the soluble manganous salts by the addition of a caustic alkali. This, according to Hannon, is a good medicinal preparation; but a strong objection to it is that it rapidly absorbs oxygen, and passes to the state of the brown hydrated sesquioxide.

Manganese Carbonate. *Mangani Carbonas*. *Manganous Carbonate*. $MnCO_3$.—This salt may be obtained by the following formula, which is that of Hannon: Dissolve seventeen ounces of crystallized manganous sulphate, and nineteen ounces of sodium carbonate, separately, in two pints of water, a fluidounce of syrup having been previously added to each pint, and, having mixed the solution in a well stoppered bottle, allow the precipitate to subside. Decant the supernatant liquid, wash the precipitate with sweetened water, allow it to drain from a cloth saturated with syrup, express, mix with ten ounces of honey, and evaporate rapidly to form a pilular mass, which is to be divided into four-grain pills. By a double decomposition between the manganous sulphate and sodium carbonate, manganous carbonate is precipitated, and sodium sulphate remains in solution. The sulphate is washed away, and the carbonate is brought to a pilular consistence with honey, which, together with the syrup, prevents the manganous oxide in the pill from rising to a higher stage of oxidation. The dose is from two to ten pills daily. Manganous carbonate was tried by Hannon as a medicine on himself. After its use for fifteen days he found his appetite improved and his pulse increased in force, and he experienced a feeling of sanguineous plethora. He afterwards exhibited the remedy in several anæmic cases, with the effect of exciting the functions to a more healthy action, increasing the strength, and improving the blood.

Manganous phosphate, tartrate, and malate have also been proposed by Hannon as useful

remedies. The phosphate is prepared by double decomposition between manganous sulphate and sodium phosphate. A *syrup of manganous phosphate* has been made by T. S. Wiegand of Philadelphia. (See his formula in A. P. J. for July, 1854.) Simpson of Edinburgh, informed Geo. B. Wood that a syrup made with two grains of ferrous phosphate and one grain of manganous phosphate, in a fluidrachm of syrup, was much and advantageously used by himself and others in Edinburgh. This may be easily prepared by adding to the two ingredients mentioned five grains of glacial phosphoric acid for each grain of the ferrous phosphate. (P. J., 1859, 288.) *Manganous lactate* has been given, associated with ferrous lactate, in *chlorosis*, in the dose of a grain (0.065 Gm.), which may be increased to five grains (0.32 Gm.).

Manganese Chloride. Mangani Chloridum. Manganchlorür, G. $\text{MnCl}_2 + 4\text{H}_2\text{O}$.—Usually obtained by evaporating the solution left after the preparation of chlorine, freeing it from excess of acid, redissolving the residue in water, treating with manganous carbonate to precipitate any iron which may be present, filtering, evaporating and crystallizing. In the form of tabular crystals or a granular powder of a pale-rose color, soluble in alcohol and water. Manganese chloride is used locally as a stimulant to *syphilitic* and other *indolent ulcers*.

Manganese Citrate. Mangani Citras.—F. B. Power (Report of Wellcome Chemical Research Laboratories No. 22) proposed the following processes: Manganese sulphate, cryst., 100 Gm.; sodium carbonate, cryst., 140 Gm.; citric acid, 62.8 Gm. The manganese sulphate and sodium carbonate are dissolved separately in a convenient quantity of water, with the aid of heat, and filtered. To the solution of manganese sulphate the sodium carbonate is added gradually, with constant stirring, and the precipitate, after being allowed to subside, is washed repeatedly by affusion and decantation with water until the washings afford not more than a slight reaction for sulphate. The moist manganese carbonate is then mixed with a little water in a porcelain dish, the citric acid added, and the mixture heated on a water bath for about half an hour, with occasional stirring. If the dry salt is desired, the product, which should form a somewhat thick mixture, is poured on a filter, washed with a little water, and dried at a gentle heat. It is thus obtained as a white crystalline powder.

Soluble Manganese Citrate was prepared as follows: To the simple manganese citrate, obtained as above from 100 Gm. of manganese sulphate, while still moist and contained in a porcelain dish, 105 Gm. of crystallized sodium citrate are added, and the mixture heated on a water bath until complete solution is effected. The liquid is then diluted sufficiently to filter readily, and at once spread on glass plates, so that on drying it may be obtained in the form of scales. The salt in the state of solution, oxidizes readily and becomes brown, but in the dry state it is quite permanent when protected from the light. The salt forms handsome pearly scales, which are very freely soluble in water.

Manganese Citrate and Iron (Soluble).—Power's process is as follows: Manganese sulphate, cryst., 100 Gm.; sodium phosphate, cryst., 240 Gm.; solution of ferric citrate (containing 8 per cent. Fe), 816.5 Gm., or a corresponding amount

of solution of other percentage strength. The salts are dissolved separately in a sufficient amount of water with the aid of heat and filtered. To the solution of manganese sulphate, while warm, is added the warm solution of sodium phosphate. The precipitate of manganese phosphate is allowed to subside, and washed by affusion and decantation with water until the washings afford not more than a very slight reaction for sulphate. The precipitate, while still moist, is then put into a porcelain dish, the solution of ferric citrate added, and the mixture heated on a water bath until complete solution is effected. It is then filtered and the liquid spread on glass to scale in the usual manner. The salt should be kept protected from the light. It forms handsome, greenish-yellow scales, which are slowly soluble in cold, but readily in warm water. It ordinarily contains about 14 per cent. of iron and 7 per cent. of manganese.

Manganese Iodide. Mangani Iodidum. Manganous Iodide. MnI_2 .—This very deliquescent salt may be prepared by adding manganous carbonate to aqueous hydriodic acid, filtering the solution, and granulating, carefully regulating the heat. This iodide may be administered in syrup or pill. Procter proposed the following formula for the *syrup*: Dissolve sixteen drachms of manganous sulphate, and nineteen drachms of potassium iodide, separately, in three fluidounces of water, each portion of water being previously sweetened with two drachms of syrup. Mix the solutions in a glass-stoppered bottle, and when the crystals of potassium sulphate have ceased to precipitate, throw the liquor on a strainer of fine muslin, and allow it to filter into a pint bottle, containing twelve ounces of powdered sugar. When the solution has ceased to pass, wash the filter with a little sweetened water, and add sufficient of that liquid to make the whole measure a pint. Lastly, agitate the liquid until the sugar is dissolved. Procter stated that this syrup contained about a drachm of manganous iodide in each fluidounce. The small proportion of potassium sulphate which remains dissolved in the syrup does not interfere with its medicinal efficacy. The dose is from ten to thirty drops (0.5–1.5 Cc.), repeated several times a day. (A. J. P., Oct. 1850.) Hannon makes a *pill of manganous iodide* by double decomposition between equal weight of potassium iodide and crystallized manganous sulphate. The salts are perfectly dried, accurately mixed in powder, and then rubbed up with honey, so as to reduce the whole to a pilular mass, which may be divided into four-grain pills. Assuming that the honey added compensates for the loss of water in drying, each pill will consist of about two grains of manganous iodide, one of potassium sulphate, and one of honey, and manganous sulphate in excess. The dose is one pill daily, gradually increased to six. According to Hannon, manganous iodide is particularly useful in the *anæmia* attendant on scrofula, phthisis, and cancer, and in syphilis. It is also affirmed that when given with cinchona it removes the enlargement of the spleen of malarial fevers.

Manganese Tannate. Mangani Tannas. Manjantannat, G.—Made by adding freshly precipitated manganese carbonate to a hot solution of tannic acid until it is neutralized, filtering and evaporating to dryness. Iron must be absent, and the solution must be protected from contact with iron or the solution and salt will acquire an inky color. It is soluble in water.

Ferro-Manganic Preparations.—Hannon conceives that manganese is peculiarly suited to the treatment of anæmic cases in which iron has failed, or acts very slowly; but, instead of passing at once from the use of iron to that of manganese, he prefers to give intermediately a mixture of the two. For this purpose he recommends the following formula. Take of crystallized ferrous sulphate six drachms and a half; crystallized manganous sulphate two drachms; sodium carbonate nine drachms; honey five drachms. Rub together, and with syrup make a mass, to be divided into four-grain pills. In this pill both the metals are present as carbonates, and, as the sodium sulphate is not washed away, it contains that salt also. The dose is from two to ten pills daily. (See the paper of Hannon, *J. P. C.*, 3e sér., xvi. 41 and 189.) The syrup of ferrous and manganous iodides may be prepared by the following formula. Take of potassium iodide 1000 grains; ferrous sulphate 630; manganous sulphate 210; iron filings 100; sugar, in coarse powder, 4800. Powder the iodide and sulphates separately, and, having mixed them with the filings, add half a fluidounce of distilled water, and triturate to a uniform paste. Then add another half fluidounce of distilled water to the paste, and triturate again, and, after an interval of fifteen minutes, add a third half fluidounce, and mix. Next transfer the magma of salts to the moistened filter, supported on a funnel, and allow it to drain into a bottle holding a little more than twelve fluidounces, and containing the sugar. After it has drained, add cold boiled water by small portions at a time, until the solution of the iodides has been displaced and washed from the crystalline magma of potassium sulphate. Finally, add sufficient cold boiled water to make the whole measure twelve fluidounces. The object of adding iron is to prevent the liberation of iodine. This syrup has a very pale straw color. It contains a little potassium sulphate, which does not injure it as a therapeutic agent. If the salts have not been all decomposed during their reaction, it will be greenish. Each fluidounce contains fifty grains of the mixed iodides, in the proportion of three parts of ferrous iodide to one of manganous iodide. The dose is from ten to thirty minims (0.6–1.8 Cc.). (Procter, *A. J. P.*, 1853, 198.) J. U. Lloyd proposed a process (*A. J. P.*, 1874, 6) whereby a less amount of potassium sulphate remained in the finished preparation. Manganous sulphate 240 gr.; potassium iodide 288 gr.; iodine 744 gr.; iron wire (small) 240 gr.; sugar 17 oz. av.; distilled water q. s. Place the iodine, three ounces of distilled water, and the iron wire in a glass flask, and agitate until the solution has acquired a clear greenish color, without a tinge of yellow. Filter the solution into the sugar contained in a porcelain dish; wash the filter by pouring into it two ounces of distilled water, allowing the liquid to filter into the sugar. Dissolve the manganous sulphate and potassium iodide separately in half an ounce of cold distilled water by trituration in a mortar; mix the two solutions together, and allow the potassium sulphate to separate; transfer the mixture to a wetted filter, and allow the solution of manganous iodide to filter into the sugar; when well drained, wash the precipitate in the funnel with half an ounce of ice-cold distilled water, and finish by agitating the mixture until the sugar is dissolved; add enough distilled water to make the whole

measure twenty fluidounces; filter. Syrup of iron and manganous iodide is considered by Pêtrequin to be particularly suited to the treatment of anæmia resulting from obstinate intermittent fevers, prolonged suppuration, and scrofulous, syphilitic, and cancerous affections.

T. S. Speer of Cheltenham, prefers a saccharine carbonate of the two metals, made by the following formula. Dissolve three ounces and one drachm of ferrous sulphate, one ounce and twenty grains of manganous sulphate, and five ounces of sodium carbonate, each, in thirty Imperial fluidounces of water, and thoroughly mix the solutions. Collect the precipitated carbonates on a cloth filter, and wash them immediately with cold water, to separate the sodium sulphate. Then press out as much water as possible, and, without delay, triturate the pulp with two and a half ounces of finely powdered sugar. Lastly, dry the mixture at a temperature not exceeding 48° C. (120° F.). The saccharine iron and manganous carbonate, as thus prepared, has a reddish-brown color, devoid of all taste, except that imparted by the sugar. The dose is five grains (0.32 Gm.), gradually increased to twenty grains (1.3 Gm.), three times a day, given with the meals, or immediately after them. (See *A. J. P.*, 1854, 127.)

Mangosteen.—The pericarp of the fruit of the *Garcinia Mangostana*, L. (Fam. Clusiaceæ), is an active astringent, and has been used as such locally in various catarrhs, and also in diarrhœa and in leucorrhœa. Dose of fluidextract, from half to one fluidrachm (1.8 to 3.75 Cc.).

Manzanillo. *Manchineel*. *Hippomane Mancinella*, L. (*Mancinella venenata*, Tussac.)—According to A. Betancourt, the milky juice of this euphorbiaceous tree, growing in the West Indies, is a violent irritant, acting as a vesicant when applied to the skin, and when taken internally in doses of twenty drops causing a fatal gastro-enteritis. In doses of two drops it acts as a powerful and very certain cathartic; it is also diuretic. In Cuba it has much repute in tetanus. (*L. M. R.*, Feb. 1889.)

Maranta. *Arrowroot*. *Arrowroot de la Jamaïque*, *Salep des Indes occidentales*, Fr. *Marantastärke*, *Amerikanisches Stärkemehl*, *Arrowmehl*, G. (Fam. Marantaceæ).—Under this name the U. S. Pharmacopœia 1870 recognized the fecula obtained from the root of *M. arundinacea*, L.

The arrowroot plant is a native of the West Indies, where it is largely cultivated for the sake of its fleshy, irregularly cylindrical rhizomes whose cells are gorged with starch granules. It is cultivated also in the East Indies, Ceylon, Sierra Leone, the south of Africa, and formerly in our Southern States, especially Georgia and Florida. The plant is easily propagated by cuttings of the root. An analysis by Macdonald (*J. Soc. Chem. Ind.*, 1887, 336) gives the following as the composition of the St. Vincent root: Starch, 27.07 per cent.; fibre, 2.82; fat, 0.26; albumen, 1.56; sugar, gum, etc., 4.10; ash, 1.23; water, 62.96; total 100.00. An analysis of the arrowroot starch from the same locality by Macdonald gave: Starch, 83.70 per cent.; fibre, 0.04; fat, 0.07; sugar, gum, etc., 0.18; ash and sand, 0.14; water, 15.87; total, 100.00. The fecula is prepared in the following manner. The rhizomes are dug up when a year old, washed, and then beaten into a pulp, which is thrown into water, and agitated so as to separate the amylaceous

from the fibrous portion. The fibres are removed by the hand, and the starch remains suspended in the water, to which it gives a milky color. The milky fluid is strained through coarse linen, and allowed to stand that the fecula may subside, which is then washed with a fresh portion of water, and afterwards dried in the sun.

The *Bermuda arrowroot* is in general the most highly esteemed. About 1897-98 the production of it in the island had almost ceased, but in 1905 twelve to fourteen tons were produced, all except a few hundredweight being exported to Great Britain. The Bermuda arrowroot of the American, and probably largely also of the English, markets, is of various sources, the name seemingly being applied to any superior product.

Other plants contribute to furnish the arrowroot of commerce. Lindley states that it is procured in the West Indies from *Calathea allouia*, Lindl. (*Maranta allouia*, Aubl.), and possibly other species, besides *M. arundinacea*, L. Under the name of *M. indica*, Tussac describes a distinct species, which he says was originally brought from the East Indies, and is now cultivated in Jamaica. This, however, is generally considered as a mere variety of *M. arundinacea*, from which it differs chiefly in having leaves more elongated at the point and smooth on both sides. Very fine arrowroot is obtained in the East Indies from the root of *Curcuma angustifolia*, Roxburgh, which is cultivated in Travancore. But the product is lighter than the *Maranta* arrowroot, and does not so quickly make a jelly. *Cassava arrowroot* is prepared in Brazil from *Manihot utilisima*, Pohl. (*Jatropha Manihot*, L.; *Janipha Manihot*, Kunth.), and sometimes sold as arrowroot or used to adulterate the true arrowroot. A variety of arrowroot has been imported from the Hawaiian Islands. Nuttall, during a visit to these islands, found that it was obtained from a species of *Tacca*, which he described by the name of *Tacca oceanica*. (*A. J. P.*, ix. 305.) The plant is in fact *Tacca pinnatifida*, Forst., from which a similar fecula is prepared in the East India province of Arracan. (*P. J.*, vi. 383.) The tuberous roots of different species of *Alstromeria*, growing in South America, yield a fecula used for the same purposes as the maranta, and a specimen, under the name of *Talcahuana arrowroot*, was sent from Chili by Ruschenberger to Carson of this city, who ascertained it to be the product of the *Alstromeria ligtu*, L. (Fam. Amaryllidaceæ). (*Ibid.* xxxii. 289.) In the West Indies, substitutes for arrowroot are furnished by the roots of *Dioscorea sativa*, L. (*D. spinosa*, Roxb.), of the fam. Dioscoreaceæ or *yam*, and of *Colocasia antiquorum*, Schott. (*Arum esculentum*, L.), of the fam. Dioscoreaceæ, or *yam*, and of *Colocasia antioxiensis*, L. (Fam. Urticaceæ), the bread-fruit tree.

Under the name of *koonti* there is prepared in Southern Florida an excellent arrowroot from the rhizomes of *Zamia integrifolia*, Jacq. (Fam. Cycadaceæ). It is characterized by muller-shaped starch granules,—i. e., like rounded irregular lumps of glass cut off at one end for pulverizing. *Koonti* is locally used, but is chiefly shipped to the Bahamas, where it is largely eaten by the negroes. The refuse of the rhizomes is esteemed in Florida as a mulch for the orange trees.

Attempts have been made to substitute finely prepared potato starch for arrowroot, and there is no doubt that in nutritive properties it is quite equal, but patients complain of an unpleasant taste of the potato which it is likely to retain.

Arrowroot is in the form of a light, white powder, or of small pulverulent masses, without odor or taste. It is firm to the touch when pressed between the fingers, and produces a faint creaking sound when rubbed. It is a pure starch, corresponding in chemical properties with that of wheat and the potato. It is liable to become musty, and should then be rejected. The odor and taste are the best criteria of its purity. It should be perfectly free from odor and unpleasant flavor. Procter rendered musty arrowroot sweet and fit for use by washing it thoroughly with two successive portions of cold water, and then drying it upon frames of muslin in a warm place. (*A. J. P.*, xiii. 188.) Arrowroot is sometimes adulterated with wheat or potato starch. These may be detected by a microscope. Hydrochloric acid has been proposed as a test. A mixture of equal parts of that acid and of water, rubbed with about half its weight of potato or wheat starch, very quickly forms so thick a mucilage that the mortar in which the trituration is effected may be raised by the pestle, while the same result does not take place with rice flour or arrowroot under twenty-five or thirty minutes. So small a proportion as from 4 to 6 per cent. of the impurity may, it is asserted, be detected in this way. (*J. P. C.*, 3e sér., ii. 246.)

The microscope offers the best means of distinguishing the different varieties of fecula sold as arrowroot, or used for its adulteration. The granules of *Maranta arrowroot* are rarely oblong, somewhat ovate-oblong, or irregularly convex, with very fine rings, a circular hilum which cracks in a linear or stellate manner, and small mammillary processes occasionally projecting from them. (Pereira.) The largest are the 750th of an inch, but many are not more than the 2000th of an inch long, and their breadth is generally two-thirds of their length. (Christison.) The granules of the *East India arrowroot* are, according to Pereira, of unequal size, ovate or oblong-ovate, flattened, and often furnished with a very short neck or nipple-like projection. The rings are numerous, close, and very fine, and the hilum, which is situated at the narrow extremity, is circular, small, and indistinct. The microscopic appearance of the *tapioca fecula* will be described under the head of *Tapioca*. The *Tacca fecula* from the South Sea Islands, examined by Pereira, consisted of circular, muller-shaped, or polyhedral granules, with few and not very distinct rings, and a small circular hilum, which cracked in a linear or stellate manner. The *potato starch* granules are of various shape and size, but generally ovate or elliptical, and from the 7000th to the 300th of an inch in length, the largest being inferior in size only to the largest of the *canna starch* or *tous-les-mois*. (See *Canna*.) They are strongly marked with concentric rings, and have a circular hilum, from which usually proceed the cracks observable in some of the larger grains.

Medicinal Properties and Uses.—Arrowroot affords a light, very mild, and easily digested article of diet, well adapted for the sick and convalescent, and peculiarly suited, from its demulcent properties, to bowel complaints. It is prepared by dissolving it in hot water or hot milk, with either of which it forms a pearly gelatinous solution, and, if in sufficient quantity, a jelly-like mass on cooling. A tablespoonful will communicate sufficient consistence to a pint of water. It should first be formed into a perfectly smooth paste with a little cold water or milk, and the boiling water

then gradually added with brisk agitation. The preparation may be rendered more palatable by lemon juice and sugar, or by wine and spices.

Maretin.—This substance is a methylacetanilide, in which the acetyl group is substituted by the group NH.CONH_2 . In this last group the urea nucleus is so strongly combined that aniline is not liberated as a decomposition product. Maretin has the structural formula:

It occurs in white, glittering, tasteless crystals, soluble only to the extent of 1 to 1050 of water, almost insoluble in ether, readily dissolved by chloroform and acetone. It melts at $183^\circ\text{--}184^\circ\text{C}$. ($361.4^\circ\text{--}363.2^\circ\text{F}$.)

It is affirmed to be a valuable antithermic, useful in hectic and other fevers, also to have no action on the kidneys, and no tendency to produce collapse. Dose, three grains (0.2 Gm.) given in powder form.

Massoi Bark.—In Eastern commerce certain aromatic barks occur under the name of massoi barks. Of these, three are believed by F. Hekmeyer to be the products respectively of *Cinnamomum xanthoneurum*, Blume, *Cinnamomum Burmanni*, Blume (*C. Kianis*, Nees), and *Massoja aromatica*, Becc. (*Sassafras gesianum*, Teijsm. and Binn.), all of the fam. Lauracæ. For a description of these barks, by E. M. Holmes, see *P. J.*, 1888, 465. The massoi bark which comes from New Guinea, and from which Messrs. Schimmel have distilled an oil resembling that of nutmeg and cloves, probably has a different origin from the true massoi bark.

Mata.—This name is given, in New Mexico, to an herb much used in that region as an addition to tobacco in smoking. It is said, when burning, to have an odor like that of the tonka bean, and, when smoked with tobacco, to correct the extremely disagreeable odor imparted by this to the clothing and apartments. From imperfect specimens of the plant raised by E. S. Wayne and sent to Maisch, it is supposed to be a *Eupatorium*, probably *E. incarnatum*, Walter, which is indigenous in Texas. (*A. J. P.*, 1868, 122.)

Meat, Raw.—Raw meat has been recommended as an article of diet for consumptive patients, and especially for scrofulous children and in other cachectic cases, and is asserted to have proven highly useful. It may also be employed with great advantage in *dyspepsia* and *chronic diarrhoea*, especially in children. It was brought into notice by Fuster of Montpellier, France. The following formula is recommended by Reveil. Take of fillet of beef 100 grammes, deprive it carefully of all fatty and membranous matter, cut it up finely, beat it in a mortar, and add of powdered sugar 20 grammes, sodium chloride 1.5 grammes, potassium chloride half a gramme, and powdered black pepper one-fifth of a gramme. The mixture is to be taken in teaspoonful (3.9 Gm.) doses through the day. (*Ann. Thér.*, 1866, 145.) An excellent method of exhibiting raw meat is to scrape a thin steak and mix the pulp thus obtained with brandy. Ivon asserts that a very pleasant emulsion is afforded by the following formula (*A. J. P.*, 1874, 346). Take of raw meat 250 parts, of sweet almonds 75 parts, of bitter almonds 5 parts, of white sugar 80 parts. Blanch the almonds and beat the whole into a paste. In dissolving, milk may be used instead of water.

Pemmican, which before the extermination of buffaloes was much used in the northwestern part of the United States as an excellent condensed food, was made by mixing equal parts of buffalo meat and buffalo tallow, and pouring the melted mixture into sacks of untanned buffalo hide. For processes for *meat biscuit* and *flour of meat*, see *U. S. D.*, 17th ed., p. 1685; see also *Extractum Carnis*, 18th ed., p. 1654.

Medeola. *Medeola virginiana*, L. *Gyromia virginica*, Nuttall. *Indian Cucumber*.—An indigenous perennial herb of the fam. Convallariacæ, growing in all parts of the United States. The root, which in shape and flavor bears a strong resemblance to a small cucumber, is said by Pursh to be eaten by the Indians, and by Barton to be useful as a diuretic in *dropsies*.

Melaleuca (Cajuputi).—Under the name of *gomenol* there has been put upon the market a volatile oil obtained from the leaves of *Cajuputi viridiflora* (Gaertn.), Lyons (*Melaleuca viridiflora*, Gaertn.), a myrtaceous plant of New Caledonia. Its sp. gr. is 0.922, and its rotatory power plus 0.42° . Its odor and taste are said to resemble those of camphor and peppermint. The chief constituent of the oil (66 per cent.) is cineol, and in addition to this is a crystallized terpeneol, $\text{C}_{10}\text{H}_{18}\text{O}$, and the valeric ester of the same. These together make up 30 per cent. additional. (Gilde-meister and Hofmann, *Etherische Oele*, p. 686.) It has been recommended in the *chronic catarrhs* of the pulmonary mucous membrane, and especially in *whooping cough*. It may be given by the mouth or exhibited in the form of intramuscular injections of a sterilized fixed oil four parts, to volatile oil one part. The hypodermic dose of a 10 per cent. solution is two and one-half fluidrachms to one-half fluidounce (9.3–15 Cc.). The injections should be practised every other day.

Melastoma. *Melastoma Ackermanni*.—This Colombian plant of the fam. Melastomacæ is used in South America as an anti-neuralgic. Its abundant essential oil resembles methyl salicylate, if indeed it be not identical with it. (See *N. R.*, Aug. and Sept., 1883.)

Melilotus. *Melilotus officinalis* (L.), Lam. *Melilot*. *Herba Meliloti*, P. G. *Yellow Sweet Clover*. *King's Clover*. *Summitates Meliloti*. *Melilot officinal*, Fr. *Steinklee*, *Melilotenkle*, G.—An annual or biennial plant of the fam. Leguminosæ, indigenous in Europe, and growing also in this country. The plant, when in flower, has a peculiar sweet odor, which, by drying, becomes stronger and more agreeable, somewhat like that of the tonka bean. This similarity is accounted for by the fact that *coumarin*, $\text{C}_9\text{H}_6\text{O}_2$, the chief constituent of tonka beans, is present in melilot, combined with *melilotic acid*, $\text{C}_9\text{H}_{10}\text{O}_3$, and *coumaric acid*, $\text{C}_9\text{H}_8\text{O}_3$, of which latter acid *coumarin* is the anhydride. *M. alba*, Desv., is a more robust species, distinguished by its white flowers. Its properties are the same as those of the yellow melilot. Melilot is practically inert.

Melissa. *U. S.* 1890. *Melissa*. *Balm*.—Under this name were formerly recognized by the U. S. P. the leaves and tops of *Melissa officinalis*, L. (Fam. Labiatæ), or the ordinary *balm* of Southern Europe, which has become naturalized in this country. Balm contains some tannic acid, and a yellowish, highly flavored essential oil which, however, is present in such small quantities that the plant has practically no remedial value. The allied *Clinopodium Calamintha* (L.), Kze. (*Me-*

lissa Calamintha, L.), is said to contain sufficient aromatic volatile oil to be of possible commercial interest.

Menispermum. U. S. 1890. *Yellow Parilla. Canadian Moonseed.*—"The rhizome and roots of *Menispermum canadense* Linné (nat. ord. *Menispermaceæ*)." U. S. 1890.

M. canadense. L.—This is a woody, climbing plant, which grows throughout Eastern North America. It is specifically characterized by its peltate three to seven-lobed leaves, its small clusters of greenish-yellow flowers, and its somewhat kidney-shaped glaucous fruit, which is ripened in the month of September. Its root was first brought into market as *Texas sarsaparilla*, and identified by Robt. P. Thomas. (*A. J. P.*, xxvii. 7.) *Menispermum* was officially described as follows: "Rhizome several feet long, 5 Mm. thick, brown or yellowish-brown, somewhat knotty, finely wrinkled longitudinally and beset with numerous thin, rather brittle roots; fracture tough, woody; internally yellowish, the bark rather thick, the wood-rays broad, porous, and longest on the lower side; pith distinct. Nearly inodorous; taste bitter." J. M. Maisch proved the presence of a white alkaloid, and of a small quantity of berberine. The former reacts with the usual alkaloidal precipitants, is not very soluble in water, but soluble in alcohol and ether. H. L. Barber (*A. J. P.*, 1884, p. 401) obtained the white amorphous alkaloid above referred to, for which Maisch proposed the name *menispine*. Starch was also found in the root. (*A. J. P.*, 1863, p. 301.) *Menispermum* has been used as a substitute for *sarsaparilla* but is probably inert. A *fluidextract* was recognized by the U. S. P. 1890; dose one-half to one fluidrachm (1.8–3.75 Cc.). The following was the official process:

"*Menispermum*, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Mix six hundred cubic centimeters [or 20 fluidounces, 138 minims] of Alcohol with three hundred cubic centimeters [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the *Menispermum* is exhausted. Reserve the first nine hundred cubic centimeters [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." U. S. 1890.

Mentha Pulegium. L. *European Pennyroyal. Pouliot commun.* Fr. *Polei.* G. *Pulegium vulgare.* Mill.—This European labiate yields an oil which is known in England as the oil of pennyroyal, and must not be confounded with the American plant of the same name. The oil, which is also known as the oil of poley, has been examined by Beckmann and Pleissner (*Ann. Ch. Ph.*, 262, 1), who discovered as the most important constituent *pulegone*, $C_{10}H_{16}O$, an unsaturated ketone, which

makes up 80 per cent. of the oil. It boils under a pressure of 60 Mm. at from 130°–131° F., turns the plane of polarization to the right, and has a sp. gr. 0.9323 at 0° C. It forms crystalline compounds with hydroxylamine and with hydrogen bromide. When reduced by sodium in ethereal solution *pulegone* is changed into menthol. *Pulegone* is most abundant in the Spanish oil, and less abundant in American and Algerian oils. (See also Wallach, *Ann. Ch. Ph.*, 272, 122, and Semmler, *Ber. d. Chem. Ges.*, 25, 3515.) It is stated (*B. M. J.*, March, 1890) that the oil is largely used for the purpose of producing abortion, and is popularly believed to be safer and more certain than the other volatile oils. Taylor denies, however, that the oil is an abortifacient and it appears to be demonstrated that it is capable of causing fatty degeneration. (See *S. Jb.*, 267, p. 230.)

Menthiodol.—This substance has been recommended as a local application in neuralgia. It is prepared by carefully heating four parts of menthol in a capsule, adding one part of finely powdered iodol, and triturating into a homogeneous mass, which is made into cones or pencils of a suitable size. If the mass is too hard, it may be softened by remelting with a minute quantity of camphor.

Menyanthes. *Menyanthes trifoliata*, L. *Buckbean. Marsh Trefoil. Bogbean. Water Shamrock. Folia Trifolii Fibrini.* P. G. *Menyanthe, Trèfle d'eau.* Fr. Cod.; *Fieberklee, Bitterklee, Dreiblatt.* G.—This gentianaceous plant is a native both of Europe and North America, from Greenland to Alaska and south to Pennsylvania, Minnesota, and California. All parts of *menyanthes* are efficacious, but the leaves were formerly official.

The taste of buckbean is intensely bitter and somewhat nauseous, the odor of the leaves faint and disagreeable. The plant has been examined by Trommsdorff, Brandes, Landerer, and Kromayer. Its virtues depend on a bitter principle denominated *menyanthin*, which may be obtained sufficiently pure for use by treating the spirituous extract of the plant with hydrated lead oxide, removing the lead by hydrosulphuric acid, filtering and evaporating the liquor, exhausting the residue with alcohol, and again evaporating with a gentle heat. It has a pure bitter taste, is soluble in alcohol and water, but not in pure ether, and is chemically neutral. Kromayer (1865) assigns to it the formula $C_{30}H_{46}O_{14}$, and states that it breaks up on heating with diluted sulphuric acid into a fermentable sugar and *menyanthol*, C_8H_8O , a colorless, difficultly volatilizable oil, with an odor like that of bitter almond. K. Leuderich (*A. Pharm.*, 1892, 38 and 48) has since studied *menyanthin*, and gives it the formula $C_{33}H_{50}O_{14}$, and states that its decomposition products are a phenol-like body, *menyanthol*, $C_7H_{11}O_2$, a resinous product, and a left-rotatory sugar. With the ordinary properties of the bitter tonics, *menyanthes* unites a cathartic power; in large doses it may cause vomiting. The dose of the powdered leaves or root as a tonic is from twenty to thirty grains (1.3–2.0 Gm.); of an infusion, prepared with half an ounce to a pint of boiling water, from one to two fluidounces (30–60 Cc.); and of the extract, ten or fifteen grains (0.65–1.0 Gm.), to be repeated three or four times a day. A drachm of the powder, or four fluidounces of the strong decoction, generally purges, and often occasions vomiting.

Mercurethyl Chloride. $\text{Hg}(\text{C}_2\text{H}_5)\text{Cl}$.—This has been proposed as a substitute for corrosive sublimate, but is not likely to come into use. (See *A. J. P.*, xlv, 337.)

Mercurialis. *Mercurialis annua*, L. *Mercury Herb.* *French Mercury*.—An herbaceous European plant, of the family of Euphorbiaceæ, which has been employed from the most ancient times as a purgative, diuretic, and emmenagogue. When boiled, it loses its acidity, and in this condition has been used as an emollient. Another species, *M. perennis*, L., or *dog's mercury*, also a native of Europe, is poisonous. (Mérat and De Lens.) Reichardt has discovered in *M. annua* a volatile alkalioid, which he named *mercurialine*. According to E. Schmidt (*P. J.*, vol. x, 29), *mercurialine* is identical with *methyamine*, CH_3NH_2 , and is associated in the mercurialis with *trimethylamine*. It is a liquid of an oily appearance, narcotic odor, and alkaline reaction; boils at 140°C . (284°F); forms salts with the acids; absorbs carbon dioxide; has a strong affinity for water; on exposure to the air it is changed into a resin of a buttery consistence, and is said to be poisonous to man; but Hugo Schulz (*A. E. P. P.*, April, 1886, 88) found that neither the fluidextract nor the herb given as food was capable of killing either the pig or the rabbit, and that four and a half grains (0.29 Gm.) of the mercurialine hypodermically injected had no effect. The urine is increased in quantity and colored reddish.

Mercuric Acetate. $(\text{CH}_3\text{COO})_2\text{Hg}$.—Colorless, laminar crystals, soluble in 4 parts of water, also in alcohol and ether. Used as a wash for freckles, in 1 to 300 solution and internally as an antisyphilitic in doses of one-sixth to one grain (0.010–0.065 Gm.).

Mercuric Albuminate. *Hydrargyri Albuminas*. *Quecksilberalbuminat*, G.—This compound is not constant and is made by adding a 4 per cent. solution of mercuric chloride to a 1 in 8 solution of desiccated egg albumin and heating. The digestion is continued for 48 hours, during which time the albumin is kept in excess. The moist precipitate is then carefully dried and mixed with enough sugar of milk to make the amount of mercuric chloride present represent 0.4 per cent. It is used as an antiseptic surgical powder.

Mercuric Amidosuccinamate. *Hydrargyri Amidosuccinamas*. *Asparagin Mercury*. *Asparagin-Quecksilber*, G. $\text{Hg}(\text{C}_4\text{H}_7\text{N}_2\text{O}_3)_2$.—Made by dissolving mercuric oxide in a warm solution of amido-succinic acid, or asparagin, and setting aside to crystallize. Colorless, needle-like crystals, soluble in water. Used in *syphilis*, subcutaneously, in a 1 per cent. solution.

Mercuric and Zinc Cyanide.—*Hydrargyri et Zinci Cyanidum* is stated by Dunstan to be a true chemical compound, with the formula $\text{Zn}_2\text{Hg}(\text{CN})_{10}$. It is a white powder, entirely insoluble in water. This substance has been very highly recommended by Lister as an antiseptic dressing, and is believed by him to be practically free from irritating or poisonous properties.

Mercuric Benzoate.—*Hydrargyri Benzoas*, $\text{Hg}(\text{C}_6\text{H}_5\text{COO})_2 + \text{H}_2\text{O}$, is obtained by double decomposition between an alkaline benzoate and a mercuric salt; it is a white crystalline, odorless, and tasteless powder, which is sparingly soluble in water, but easily in alcohol as well as in aqueous solutions of sodium chloride, the latter effect being due to its property of forming easily soluble double salts with the haloids. It has been strongly recommended by Stukowenkow for

hypodermic use and in *gonorrhœa*. For urethral injections the solution may be 1 to 1000 or 2000, with an equal quantity of sodium chloride. For subcutaneous injections it is employed in conjunction with cocaine, the following being the proportions: mercuric benzoate, 0.2 to 0.3; sodium chloride, 0.1; cocaine hydrochloride, 0.15; distilled water, 40. (*A. Pharm.*, April, 1889.)

Mercuric Chloride-urea Solution. *Hydrargyri Chloridi Carbamidum*. *Hydrargyrum bichloratum carbamidatum solutum*.—As the solution quickly changes it should be prepared extemporaneously as follows: 1 Gm. of mercuric chloride is dissolved in 100 Cc. of water with the aid of heat, and, when cold, 0.5 Gm. of urea is added and the liquid filtered. The solution is given in doses amounting to 15 minims (0.9 Cc.) in 24 hours, equal to one-sixth grain (0.010 Gm.) of mercuric chloride. It is employed subcutaneously in *syphilis*.

Mercuric Cyanide. *Hydrargyri Cyanidum*. *U. S.* 1890. $\text{Hg}(\text{CN})_2 = 250.18$. *Hydrargyri Cyanuretum*, *U. S.* 1850. *Cyanide of Mercury*. *Hydrargyrum Cyanatum* (*Borussicum*).

The process for the preparation of this substance, given in the *U. S. P.* 1870 was: "Take of Ferrocyanide of Potassium five troyounces; Sulphuric Acid four troyounces and one hundred and twenty grains; Red Oxide of Mercury, in fine powder, Water, each, a sufficient quantity. Dissolve the Ferrocyanide of Potassium in twenty fluidounces of Water, and add the solution to the Sulphuric Acid, previously diluted with ten fluidounces of Water, and contained in a glass retort. Distil the mixture nearly to dryness into a receiver, containing ten fluidounces of Water and three troyounces of Red Oxide of Mercury. Set aside two fluidounces of the distilled liquid, and to the remainder add, with agitation, sufficient Red Oxide to destroy the odor of hydrocyanic acid. Then filter the solution, and, having added the reserved liquid, evaporate the whole in a dark place, in order that crystals may form. Lastly, dry the crystals and keep them in a well-stopped bottle, protected from the light." *U. S.* 1870.

The formula of the *U. S. P.* 1870 is based upon that of Winckler. Hydrocyanic acid is generated by the action of sulphuric acid on potassium ferrocyanide, and, being received in a vessel containing water and a portion of mercuric oxide, reacts with the oxide, according to the reaction

generating, by double decomposition, water, and mercuric cyanide which is held in solution. Sufficient mercuric oxide is not used at first to saturate the whole of the hydrocyanic acid generated, because should there happen to be any excess of the oxide there would be produced on evaporation, instead of the substance wanted, a peculiar salt composed of cyanide and mercuric oxide, which would crystallize in small acicular crystals. Hence a portion of the water still containing uncombined hydrocyanic acid is set aside, to be added to the liquid in which the acid had been completely saturated by the addition of mercuric oxide, and thus at least neutralize any mercuric oxide that might be present in it in excess. A surplus of hydrocyanic acid would be of no disservice, except for the loss of material incurred, as it is evaporated in the subsequent concentration. Mercuric cyanide should be kept in well-stoppered, dark amber-colored bottles.

Properties.—"Colorless or white, prismatic crystals, odorless, and having a bitter, metallic

taste (the salt is exceedingly poisonous). Becoming dark-colored on exposure to light. Soluble, at 15° C. (59° F.) in 12.8 parts of water, and in 15 parts of alcohol; in 3 parts of boiling water, and in 6 parts of boiling alcohol; very sparingly soluble in ether. When slowly heated in a glass tube, the salt decrepitates, and decomposes into metallic mercury and inflammable cyanogen gas, which burns with a purple flame. On further heating, the blackish residue, consisting of paracyanogen with globules of metallic mercury, is wholly dissipated. If 1 part of the salt be gently heated with 1 part of iodine in a dry test-tube, it will afford at first a yellow sublimate which afterwards becomes red, and above this a sublimate of colorless, needle-shaped crystals will be formed. On adding hydrochloric acid to the aqueous solution of the salt, the odor of hydrocyanic acid is evolved. A 5 per cent. aqueous solution of the salt should be neutral to litmus paper, and should not yield, on the gradual addition of a few drops of potassium iodide test-solution, either a red or a reddish precipitate, soluble in an excess of the precipitant, nor should it yield a white precipitate with silver nitrate test-solution (absence of *mercurio chloride*).^{U. S. 1890.} In composition, it is a normal mercuric cyanide, consisting of one atom of the metal and two atoms of cyanogen, its formula being HgC_2N_2 , or $\text{Hg}(\text{CN})_2$.

Mercuric cyanide has been used as a substitute for corrosive sublimate, with the statement that it is less irritating, equally germicidal, and free from action upon surgical instruments. Prochown gives from twenty-five to thirty-five drops of a 1 per cent. solution hypodermically without causing local irritation, and with great asserted benefit, in chronic *syphilis*. Chaleix (*Journ. de Méd. de Paris*, March, 1900) reports death from the use of a vaginal injection containing fourteen grains of mercuric cyanide. Dose, internally, from one-sixteenth to one-eighth of a grain (0.004–0.008 Gm.).

Mercuric Formamide Solution. *Hydrargyri Formamidum.* *Hydrargyrum formamidatum solutum.* *Quecksilberformamidlösung.* G.—A solution made by dissolving freshly precipitated mercuric oxide, obtained from 10 Gm. of mercuric chloride, in a sufficient amount of formamide, and adding sufficient water to make 1000 Cc. It is intended for hypodermic injection in *syphilis*, sixteen minims (1 Cc.) of the solution being given in 24 hours, corresponding to one-sixth grain (0.010 Gm.) of mercuric chloride.

Mercuric Gallate. *Hydrargyri Gallas.* *Mercurigallat.* G. $[\text{C}_6\text{H}_2(\text{OH})_3\text{CO}_2]_2\text{Hg}$.—Made by rubbing together molecular proportions of gallic acid and moist precipitated mercuric oxide and drying the product. It forms a blackish or greenish powder, insoluble in most solvents. The compound is used in place of the tannate, which is less stable, as an antisyphilitic, in doses of from one-half to one grain (0.032–0.065 Gm.) daily.

Mercuric Iodotannate. *Hydrargyri Iodotannas.*—Iodotannate of Mercury, according to J. Nourry (*B. G. T.*, April, 1888), is a soluble, non-irritating compound. For hypodermic use a solution is prepared from mercury 0.008 Gm., iodine 0.03 Gm., kramerotannic acid 0.04 Gm., and glycerin 1 Cc.

Mercuric Lactate. *Hydrargyri Lacticum.* $(\text{C}_6\text{H}_5\text{O}_3)_2\text{Hg}$.—It forms a white crystalline powder, soluble in water. This preparation has been used hypodermically in dose of one-sixth grain (0.010 Gm.) a day.

Mercuric Oxycyanide. *Hydrargyri Oxycyanidum.* $\text{Hg}_2\text{O}(\text{CN})_2$.—This oxycyanide has been suggested as a substitute for corrosive sublimate (dose the same), for hypodermic use in *syphilis*, and as a local agent in *conjunctivitis* and *gonorrhoea*; 1 to 5000, increased as borne.

Mercuric Peptonate. *Hydrargyri Peptonas.* Under this name there has been introduced a yellowish liquid, having a saline feebly metallic taste and slightly acid reaction. It is a solution of mercuric peptonate and it is alleged that it may be used hypodermically without production of pain. Fifteen minims (0.9 Cc.) is said to be equivalent to one-sixth of a grain (0.010 Gm.) of mercuric chloride. As a substitute for this has been proposed *gluten-peptone sublimate*. This has been introduced as a white lustrous hygroscopic powder, or more commonly in 1 per cent. solution. It is said to contain 25 per cent. of corrosive sublimate, and to be an efficient, non-irritating preparation for hypodermic use.

Mercuric Phenylate.—*Hydrargyri Carbolas, Mercuric Carbolate*, $(\text{C}_6\text{H}_5\text{O})_2\text{Hg}$, occurs as colorless needles, insoluble in water and cold alcohol, but taken up by hot alcohol, by ether, or a mixture of alcohol and ether, and by glacial acetic acid. This substance has been used as an antisyphilitic in doses of from a third to a half grain (0.021–0.032 Gm.).

Mercuric Pyroborate.—*Hydrargyri Pyroboras*, HgB_4O_7 , is an amorphous, brown, insoluble powder, which has been commended by V. Tokayer (*Ph. Post*, 1892) as a local application in the treatment of specific and other ulcerations.

Mercuric Salicylate. *Hydrargyri Salicylas.* *Neutral Mercuric Salicylate*.—This is a white, amorphous, tasteless and odorless powder, scarcely soluble in alcohol and water, and having the formula $(\text{C}_6\text{H}_4\text{OHCO}_2)_2\text{Hg}$. It was first introduced as a remedy by Silva Araujo of Rio Janeiro, who affirmed that it had less influence upon the alimentary tract, that it was better borne than any other preparation of mercury, and that it was also more effective in *syphilis*.

The statements of Araujo have, in a measure, been confirmed by various physicians, and especially has it been asserted that the salicylate may be given by intra-muscular injection without producing local effects, and with a rapid mercurialization of the system. The dose internally is from one-fourth to one grain (0.016–0.065 Gm.), two or three times a day. Hypodermically, one-sixth of a grain (0.010 Gm.) may be given with an equal amount of potassium carbonate, in distilled water.

Mercuric Sozoiodolate. *Hydrargyrum Sozoiodolicum.* $(\text{C}_6\text{H}_4\text{I}_2(\text{OH})\text{SO}_3)_2\text{Hg}$.—This compound is a lemon-yellow powder, scarcely soluble in water, but more so in solution of sodium chloride. This preparation, which is said to contain 31 per cent. of mercury and 38 per cent. of iodine, has been especially recommended by Witthauer (*M. M. W.*, Aug. 1892) in the treatment of *syphilitic ulcerations, enlarged glands*, and skin diseases, in the form of a 1 per cent. ointment. The 1 per cent. solution is also used by Genzmer, as an injection into diseased joints, etc.

Mercuric Subsulphate, Yellow. *Hydrargyri Subsulphas Flavus.* U. S. 1890. *Yellow Mercurio Subsulphate.* *Basio Mercuric Sulphate.* *Turpeth Mineral.* $\text{Hg}(\text{HgO})_2\text{SO}_4 = 722.61$. *Hydrargyri Sulphas Flava*, U. S. 1870. *Hydrargyri Subsulphas.*

“Mercury, one hundred grammes [or 3 ounces av., 230 grains]; Sulphuric Acid, thirty cubic

centimeters [or 1 fluidounce, 7 minims]; Nitric Acid, twenty-five cubic centimeters [or 405 minims]; Distilled Water, a sufficient quantity. Upon the Mercury, contained in a capacious flask, pour the Sulphuric Acid, previously mixed with fifteen cubic centimeters [or 243 minims] of Distilled Water, then add, very gradually, the Nitric Acid, previously mixed with twenty-five cubic centimeters [or 405 minims] of Distilled Water, and digest at a gentle heat until reddish fumes are no longer given off. Transfer the mixture to a porcelain capsule, and heat it on a sand-bath, under a hood or in the open air, with frequent stirring, until a dry, white mass remains. Reduce this to a fine powder, and add it in small portions at a time, with constant stirring, to two thousand cubic centimeters [or 67 fluidounces, 5 fluidrachms] of boiling Distilled Water. When all has been added, continue the boiling for ten minutes; then allow the mixture to settle, decant the supernatant liquid, transfer the precipitate to a strainer, wash it with warm Distilled Water, until the washings no longer have an acid reaction, and dry it in a moderately warm place. Keep the product in well-stoppered bottles, protected from light." U. S. 1890.

When normal mercuric sulphate is thrown into boiling or even warm water it is instantly decomposed, and an insoluble salt is precipitated, which is turpeth mineral. Its composition is Hg_3SO_6 , or, more clearly expressed, $\text{Hg}_2\text{SO}_4 + 2\text{HgO}$; that is, a compound of one molecule of mercuric sulphate and two molecules of mercuric oxide.

Yellow mercuric sulphate is "a heavy, lemon-yellow powder, odorless and almost tasteless; permanent in the air. Soluble in about 2000 parts of water at 15° C. (59° F.), and in 600 parts of boiling water; insoluble in alcohol; readily soluble in nitric or hydrochloric acid. When heated, the salt turns red, becoming yellow again on cooling. At a red heat it is volatilized, evolving vapors of mercury and of sulphur dioxide, and leaving no residue. A solution of the salt in nitric or hydrochloric acid, diluted with water, gives with potassium iodide test-solution a red precipitate, and with barium chloride test-solution a white one. The salt should be completely soluble in 10 parts of hydrochloric acid (absence of mercurous salt or of lead)." U. S. 1890. It was originally called *turpeth mineral*, from its resemblance in color to the root of *Ipomœa Turpethum*.

Turpeth mineral is capable of acting as a mercurial and producing pytalism. It is, however, in full dose violently emetic, and in modern medicine has been chiefly used in true croup, especially on account of its very high recommendation by Fordyce Barker. It is a dangerous remedy, especially with young children, several cases having been reported in which, failing to cause vomiting, it has produced death preceded by symptoms similar to those of corrosive sublimate poisoning. (See *M. News*, xliii. 1883; also, *London Med. Gaz.*, 1847.) Emetic dose for a child two years old, two to three grains (0.13–0.2 Gm.); for adult, three to five grains (0.2–0.32 Gm.), repeated in fifteen minutes if it does not operate. Alterative dose, one-fourth to half a grain (0.016–0.032 Gm.).

Mercuric Succinimide. *Hydrargyri Succinimidum.* $(\text{C}_4\text{H}_4\text{O}_2\text{N})_2\text{Hg}$.—This drug may be formed by heating together succinic acid, carbonic anhydride, and ammonia, which combine with mercuric oxide to form a compound which occurs as a white silky powder soluble in water. This solu-

tion remains quite unchanged when kept. According to Vollert, the solution of one and three-tenths grammes of this salt in one hundred of water is free from irritant properties, and when used hypodermically produces no disagreeable local or even secondary symptoms. (*Th. M.*, 1888.)

Mercuric Sulphate. *Hydrargyri Sulphas. Hydrargyrum Sulphuricum.* Normal Mercuric Sulphate. *Sulfate mercurique*, Fr. *Mercurisulfat*, G. HgSO_4 .—Made by heating together 18 parts of mercury, 10 parts of concentrated sulphuric acid, 3 parts of water and 4 parts of 25 per cent. nitric acid, in a flask, on a sand bath, until reddish vapors cease to be given off, then drying with the aid of heat, in an open dish, constantly stirring. It is a heavy white crystalline powder, used in making turpeth mineral, and mercuric and mercurous chlorides. It has no use in medicine.

Mercuric Sulphide. U. S. 1880. *Hydrargyri Sulphidum Rubrum. Red Sulphide of Mercury. Cinnabar.* $\text{HgS} = 230.33$. *Hydrargyri Sulphuretum Rubrum*, U. S. 1870. *Cinnabaris. Hydrargyrum Sulfuratum Rubrum*, P. G. *Sulfuretum Hydrargyricum. Sulfure rouge de Mercure*, Fr. *Roths Schueffelquecksilber, Zinnober*, G.—This preparation, which was formerly official both in the United States and British Pharmacopeias, has been finally dropped from each. It can be made by mixing together forty parts of mercury and eight parts of sulphur, and subliming the mass after it has become cold. In order to render the combination more prompt, the sulphur is first melted, and the addition of the mercury should be made gradually, while the mixture is constantly stirred. Barker recommends the addition of the metal by straining it upon the melted sulphur through a linen cloth, whereby it falls in a minutely divided state. When the temperature has arrived at a certain point, the combination takes place suddenly with a slight explosion, attended by the burning of the sulphur, which must be extinguished by covering the vessel. A black mass will thus be formed, containing generally an excess of sulphur, which, before the sublimation is performed, should be separated by gently heating the powdered mass on a sand bath. The sublimation is best performed, on a small scale, in a closely stoppered glass flask, which should be placed in a crucible containing sand, and thus arranged, exposed to a red heat. The equivalent quantities for forming this sulphide are 31.83 of sulphur and 198.5 of mercury.

Cinnabar is seldom prepared on a small scale, being made in large quantities for the purposes of the arts. Until within a few years it was nearly all manufactured in Europe, but it is now made to an enormous extent in this country. In Holland, where it is largely manufactured, the sulphur is melted in a cast iron vessel, and the mercury is added in a divided state, by causing it to pass through chamois leather. As soon as the combination has taken place, the iron vessel is surmounted by another, into which the cinnabar is sublimed. The larger the quantity of the materials employed in one operation the finer will be the tint of the product. It is also important in the manufacture to use pure materials, and to drive off any uncombined sulphur which may exist in the mass before submitting it to sublimation. In the United States, Martin's method, consisting of the agitation together of quicksilver, sulphur, and an alkaline sulphide, appears to have the pref-

erence. Another process for its manufacture in the wet way very largely employed is Brunner's. (Wagner's *Chem. Tech.*, 13th ed., 1889, 552.)

Properties.—"Brilliant, dark red, crystalline masses, or a fine, bright scarlet powder, permanent in the air, odorless and tasteless, insoluble in water, alcohol, nitric or hydrochloric acid, or in dilute solutions of alkalis. It is dissolved by nitrohydrochloric acid with separation of sulphur. When heated, the salt becomes brown and then black, but, on cooling, it reassumes its red color. At a higher temperature it takes fire, burns with a bluish flame, emitting the odor of burning sulphur, and is finally volatilized without residue. On dissolving the salt in nitrohydrochloric acid and adding an excess of stannous chloride, metallic mercury is precipitated. If the salt be treated with warm solution of potassa, the filtrate, after being acidulated with hydrochloric acid, should not yield a yellow or orange-colored precipitate (arsenic, antimony) nor should it produce a colored precipitate with acetate of lead (chromates, iodides, or other sulphides). If the salt be digested with diluted nitric acid for five minutes, the filtrate, after being much diluted, should not be darkened by hydrosulphuric acid (abs. of red oxide of mercury or of lead)." *U. S.* 1880. In close vessels at a red heat it sublimes without decomposition, and condenses in a mass, composed of a multitude of small needles. When duly levigated, it furnishes a brilliant red powder, which is the paint called *vermilion*. The same compound occurs native, being the sole ore—*cinnabar*—from which mercury is extracted. The preparation, if purchased in powder, should be carefully examined, as, in that state, it is sometimes adulterated with red lead, dragon's blood, or chalk. If red lead be present, acetic acid digested with it will yield a yellow precipitate (lead iodide) with potassium iodide. Dragon's blood may be detected by alcohol, which will take up the coloring matter of that substance, if present, and, if chalk be mixed with it, effervescence will be caused on the addition of an acid.

Cinnabar is at present only employed in medicine by fumigation, as a rapid sialagogue, in syphilitic affections, when it is desired to obtain an immediate mercurial impression. Half a drachm may be thrown on a red-hot iron, in a close apartment, and fumes inhaled as they arise. These consist of sulphurous acid gas and mercurial vapor, the former of which must prove highly irritating to the patient's lungs. A better substance for mercurial fumigation is black mercurous oxide.

Mercuric Thymolacetate. *Hydrargyri Thymolacetatas*. *Thymolquecksilberacetat*, G. ($C_{10}H_{13}O$) $Hg-HgC_2H_5O_2$.—Made by adding a warm alkaline thymol solution to a warm solution of mercuric acetate as long as the precipitate which forms redissolves on shaking. The crystals are afterwards purified by recrystallizing from dilute sodium hydroxide solution. In colorless crystals, not readily soluble in water or alcohol, very soluble in alkaline solution, from which it is precipitated by acids. It contains about 55 per cent. of mercury. Used by injection, in *syphilis*, suspended in liquid petrolatum, one-fifth grain (0.012 Gm.) being given once a week.

Mercuric Thymolate. *Hydrargyri Thymolas*. $C_{10}H_{12}OHgOH$.—Made by precipitating a solution of mercuric nitrate with sodium thymolate. An unstable, violet-green powder.

Mercuric Thymolnitrate. *Hydrargyri Thymolnitratis*.—This salt, ($C_{10}H_{13}O$) $Hg.HgNO_3$, and

mercuric thymosulphate [$(C_{10}H_{13}O)Hg.Hg$] SO_4 , have been used with asserted benefit in *syphilis*, in hypodermic doses of from one-twelfth to one-sixth of a grain (0.005–0.010 Gm.). (See *Merck's Jahresbericht*, 1891, 1892; also W. K. W., March, 1892.) Besides these preparations *mercuric naphtholate*, a lemon-yellow powder, containing 30.8 per cent. of mercury, and the *mercuric formamidate*, a solution obtained by the action of formamide upon mercuric oxide, and the *mercury tribromophenol acetate*, containing about 30 per cent. of quicksilver, have been put upon the market; also under the name of *Hydrargyrol*, *mercury paraphenylthionate* ($C_6H_4.OH.SO_3$) $_2Hg$, has been suggested as an antiseptic, but in proportion to its cost is probably of no practical value.

Mercurous Acetate. *Hydrargyri Acetas*. *Mercuracetat*, G. CH_3COOHg .—White, scaly crystals, soluble in about 330 parts of water, insoluble in alcohol and ether. It should be kept dry and away from light as it is decomposed, by boiling water and exposure, into mercury and mercuric acetate. Used internally in doses of from one-fifth to one grain (0.012 to 0.065 Gm.) for *syphilis*.

Mercurous Bromide.—*Hydrargyri Bromidum*, $HgBr$, is formed by adding potassium bromide to mercurous nitrate. It falls as a white curdy precipitate. *Mercuric bromide* ($HgBr_2$) may be obtained by digesting mercurous bromide in water containing bromine. A. E. Ebert prepared it by reaction between potassium bromide and official solution of mercuric nitrate. For the particulars of the process, see a paper by Ebert in the *A. J. P.*, March, 1867, 107. It is in the form of colorless crystals, soluble in water and alcohol. Exposed to heat it melts and sublimes. These bromides are analogous in composition and medicinal properties to the corresponding mercury iodides. Mercurous bromide is given in the dose of a grain (0.065 Gm.) daily, gradually increased. Mercuric bromide resembles corrosive sublimate, is an irritant poison, and may be administered in doses of the fifteenth of a grain (0.004 Gm.), gradually increased to one-fourth (0.016 Gm.), either in the form of pill or in ethereal solution made by dissolving a grain in a fluidrachm of ether.

Mercurous Sulphide. *Hydrargyri Sulphidum Nigrum*. *Black Sulphide of Mercury*. *Ethiops Mineral*.—This now disused remedy was prepared as follows: "Take of Mercury, Sulphur, each, a pound. Rub them together till all the globules disappear." *U. S.* 1850. For properties, see *U. S. D.*, 14th ed., 1259.

Mercurous Sulphocyanate. *Hydrargyri Sulphocyanas*. $Hg(CNS)$.—This substance, formerly called sulphocyanide of mercury, is produced by mixing diluted solutions of mercurous nitrate and potassium sulphocyanate. The white precipitate which falls, after drying, swells up suddenly when heated, giving off nitrogen, carbon disulphide, and poisonous vapor of mercury, leaving a gray residue, *mellone*. The salt is used in the preparation of the toy, *Pharaoh's serpents*.

Mercurous Tannate. *Hydrargyri Tannas*. Mercurous tannate, which was first brought forward by Lustgarten (*N. Y. M. J.*, March, 1892), has received some favor at the hands of syphilographers, and is official in the Austrian Pharmacopœia under the name of *Hydrargyrum tannicum oxydulatum*. It is declared that it has the especial advantage of being unabsorbed in the stomach, but decomposed by

the alkaline juices of the duodenum, in such a way as to yield very minute globules of metallic mercury for ready absorption. It may be prepared either by precipitating concentrated solution of tannic acid and mercurous nitrate or by rubbing together tannic acid and mercurous nitrate. According to Lustgarten, the first process yields the better preparation. It is asserted that it does not irritate the alimentary canal. In *syphilis*, three grains (0.2 Gm.) may be given to the adult daily, increasing to five grains (0.32 Gm.) or more until one hundred or one hundred and fifty grains (6.5–9.8 Gm.) have been taken.

Mesembryanthemum. *Mesembryanthemum crystallinum*, L. *Iceplant*. *Diamond Fig*. *Glaciale*, *Cristalline*, Fr. *Eiskraut*, G.—A biennial plant of the fam. *Picrodaceæ*, a native of the south of Europe. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. H. Mangon obtained as much as 43 per cent. of salts of potassium and sodium from the dried leaves. (A. J. P., 1883, 370.) The herb is without odor, and has a saline somewhat nauseous taste. It is considered demulcent, diuretic, and has been useful in *inflammations of the pulmonio and genito-urinary mucous membrane*.

Mesenna. *Musenna*. *Bisenna*. *Muséna*, *Moucéna*, Fr. *Musenarinde*, G.—Under these different names has been brought into notice, as a powerful *tanifuge*, the bark of an Abyssinian tree, *Albizzia anthelmintica* (Baill.), Courd. (*Acacia anthelmintica*, Baill., *Besenna anthelmintica*, Rich.) (Fam. *Leguminosæ*). The bark is in flat pieces from five to ten inches long, smooth, slightly fissured, of a rusty gray color exteriorly, and pale yellow and fibrous within. It consists of four layers, one of which contains very large cells, with thick coats, and is supposed to be the active part. E. Caventou and Legendre found in the bark no alkaloid, but a peculiar, acid, acrid, resinous substance. The *musennin* of Theil is probably the same, although not as yet in a pure state. The Abyssinians employ the powdered bark, in the dose of about two ounces, suspended in water or other liquid, or mixed with flour in the form of bread, or made into a confection with honey, butter, etc. It is taken in the morning, three or four hours before breakfast, and no other precautions are used. It produces no pain nor any disturbance of the functions, not even purging actively. Fragments of the worm are voided the same evening, and the greater portion of it the next day.

Mesotan. *Salicylic acid Methyloxymethylester*.

$\text{C}_6\text{H}_4 \begin{cases} \text{OH} \\ \text{COOCH}_2\text{OCH}_3 \end{cases}$ This preparation is a yellow clear fluid with a peculiar odor, miscible in all proportions with ordinary oils. It has been brought forward as a local application in all forms of *rheumatism*. In from half an hour to an hour after its local application the presence of salicylic acid can be demonstrated in the urine. When applied pure to the skin and confined by waxed paper or other appropriate dressing it produces redness and sometimes pronounced burning pains, so that it should be diluted with olive or castor oil. Even when diluted mesotan may produce *eczematous, urticarial*, or other eruption upon the skin, requiring its removal or further dilution. From one and a half to two and a half fluidrachms (5.5–9.3 Cc.) of an oily solution, containing 20 to 50 per cent. of mesotan, may be applied daily to the affected part.

Methacetin. *Para-acetanisidine.* *Para-oxymethylacetanilide*. $\text{C}_6\text{H}_4(\text{OCH}_3).\text{NHC}_2\text{H}_5\text{O}$.—This differs from acetanilide in having an atom of the nucleus replaced by the oxymethyl group (OCH_3) or from acetphenetidin by having oxymethyl instead of oxyethyl as a replacing group. It forms lustrous crystals free from color, odorless, melting at 127°C . (260.6°F .), and distilling at higher temperatures unchanged. It is scarcely soluble in cold water, readily soluble in hot water, soluble in alcohol, acetone, chloroform, glycerin, and fatty oils. According to F. Mannert, when given in toxic dose to rabbits, it causes convulsions and death through its action on the central nervous system, and is germicidal in 1 per cent. solution. Methacetin appears to be a powerful antipyretic, producing in fever a very marked fall of temperature, with a slow after-rise; this effect being accompanied by a violent sweating, which, especially in *phthisis* and allied diseases, greatly interferes with the practical use of the drug. It has also been much used in *acute rheumatism*, but is not as effective as the salicylates. As an analgesic, in *ataxic and neuralgic pains*, it appears to be distinctly inferior to phenacetin and antipyrine. No eruption from it has been noticed. During its administration the urine responds to Trommer's test, but does not contain sugar, nor is there hemoglobinuria. Dose for adults, eight grains (0.5 Gm.).

Methethyl.—Under this name there has been offered for use as a local anæsthetic a colorless neutral liquid, having a boiling point of 10.6°C . (51°F .) and a specific gravity of 0.9173 at 3.9°C . (39°F .). It is said to be ethyl chloride with a little methyl chloride and chloroform. (*Ph. Ztg.*, xliii.)

Methonal. $(\text{CH}_3)_2\text{C}(\text{SO}_2\text{CH}_3)_2$. *Dimethylsulphonedimethylmethane*.—In the form of colorless crystals, made by a process similar to that for preparing sulphonal, excepting that methylmercaptan is used in place of ethylmercaptan. It is used as a hypnotic in doses of from twenty to forty grains (1.3–2.6 Gm.).

Methyl Alcohol. *Methylic Alcohol.* *Spiritus Pyroxylicus Rectificatus*, Br. 1864. *Pyroligneous Spirit*. *Pyroxylic Spirit*. *Wood Spirit*. *Wood Alcohol*. *Wood Naphtha*. *Alcool méthylique*, *Alcool formique*, *Alcool de Bois*, *Esprit de Bois*, *Esprit pyroligneux*, Fr. *Holzgeist*, *Methylalcohol*, G. $\text{CH}_3.\text{OH}$.—Methyl alcohol was discovered in 1812 by Taylor. When wood is subjected to destructive distillation, there is formed, besides acetic acid, tar, and other products (see *Creosotum*, p. 402), about 1 per cent. of an inflammable volatile liquid, which, when separated and purified, constitutes methyl alcohol. The crude liquor, derived from the wood, separates on standing into two liquids; the heavier containing the tarry matters, and the lighter consisting of water, acetic acid, methyl alcohol, etc. The lighter liquid is saturated with lime, and subjected to distillation, whereby the impure methyl alcohol first comes over, mixed, however, with various compounds, among which are aldehyde and pyroacetic spirit (acetone). This, after having been redistilled and deprived of water by repeated rectifications from lime, forms the methyl alcohol of commerce. The commercial spirit may be purified by adding to it as much calcium chloride as it can dissolve, and allowing the mixture to stand for a few days. The methyl alcohol unites with the calcium chloride, and the compound formed is subjected to distillation to separate cer-

tain contaminating substances, which distil over. Finally, the methyl alcohol is separated from the calcium chloride by the addition of water and a new distillation, and from water by rectification from dry lime. Methyl alcohol, like the other monatomic alcohols, can also be formed synthetically in a variety of ways,—from marsh gas, from formic acid, and from formaldehyde. Pure anhydrous methyl alcohol is a mobile, colorless liquid, possessing a hot, pungent taste, and a peculiar odor, recalling that of acetic ether. It mixes in all proportions with water, alcohol, and ether, without having its transparency disturbed. It burns like alcohol, but with a less luminous flame. Its sp. gr. as a liquid is 0.8021 at 15.5° C. (59.9° F.). Its vapor is irritating to the eyes. It boils at 66° C. (150.8° F.) (according to other authorities at 55° C., when absolutely anhydrous), and during ebullition its vapor causes concussions, which render its distillation difficult, but may be prevented by placing in the bottom of the vessel a layer of mercury. As a solvent it resembles alcohol, all bodies soluble in that menstruum being likewise soluble in it. Methyl alcohol is the first of a series of organic hydroxides known as *alcohols*. It may be considered as a molecule of water in which one hydrogen atom is replaced by the monad group CH_3 (methyl), derived from marsh gas (methane) by the withdrawal of one hydrogen atom. These organic hydroxides are basic, and form with both organic and inorganic acids salts called *esters*.

The official pyroxylic spirit was directed in the Br. Pharmacopœia to have a sp. gr. from 0.841 to 0.846. From the density thus recognized, it might be implied that not the pure but the commercial pyroxylic spirit was contemplated, which has a straw-yellow color and a powerful odor of wood smoke. But the Pharmacopœia also directed that the spirit should be without action on litmus paper, free from smoky taste, and not rendered turbid by water. It therefore intended a purified spirit, and the greater density must be ascribed to the presence of the 10 per cent. of water allowed. According to Morson of London, the impure commercial spirit, which is unfit for medicinal use, may be purified "by largely diluting it with water, when an oily substance separates, after the removal of which the spirit may be recovered by distillation." By passing the mixed liquids through animal charcoal the purification is rendered more complete. Pyroxylic spirit has been confounded with pyroacetic spirit. They may be distinguished, according to Scanlan, by calcium chloride, which is without action on the latter, but dissolves in the former. In applying the test, a drop or two of a saturated solution of calcium chloride is added to the doubtful liquid in a test tube. This solution is immiscible with pyroacetic spirit, separating after agitation, but dissolves instantly in pyroxylic spirit. The liquid examined must be so pure as not to separate into two layers, nor to become milky with water.

It is sometimes desirable to be able to distinguish the presence of methyl alcohol in ordinary alcohol, and in ether or nitrous ether which may have been prepared from the methylated instead of the pure spirit. For this purpose the official test is the best which has been proposed (see Test for methyl alcohol under *Alcohol*, page 105).

Columbian spirit is simply a brand of wood alcohol of a higher quality, free from empyreumatic odor and with only a slight trace of acetone as impurity.

Methylated spirit, much used in England, contains nine parts of ethyl alcohol to one part of methyl alcohol.

Crude methyl alcohol is very largely used in the arts as a solvent, especially in the formation of varnish and other resinous solutions. It is also considerably employed as a source of heat, but the ordinary varieties of the spirit during burning give off a very offensive odor.

Methyl alcohol is capable of producing an intoxication similar to that caused by ethyl alcohol, but distinct in the slowness of the onset and the extraordinary duration of the symptoms, which may last from three to four days after the comparatively moderate dose of the drug. After distinctly toxic doses the fall of the bodily temperature is very marked, and convulsive movements of rhythmic or choreic character, followed for a day or two by loss of sensation and of reflex movements are common phenomena. Hemorrhage, also, frequently occurs from the abdominal tract. The eyes are specially affected, nystagmus of a pronounced type often being present; also, dilatation of the pupil. Chronic methyl alcohol poisoning is far more dangerous than is ordinary alcoholism, and amblyopia due to degenerative changes in the ganglion cells of the retina is a very common phenomenon. Both in human poisoning and in that produced upon the lower animals experimentally, excessive fatty degeneration of the liver and other organs is usually found after death.

Methyl alcohol amblyopia may appear after a single debauch. It is accompanied with contraction of the field of vision, absolute, usually central, scotoma, and rapid failure of vision, and though temporary improvement may occur, in 90 per cent. of the cases it ends in permanent loss of useful vision. It is worthy of note that in many cases methyl alcohol amblyopia has resulted from the excessive use of essence of ginger, or peppermint, or other aromatics, in the preparation of which the alcohol has been used as a menstruum. The permanency and severity of the symptoms caused by methyl alcohol depend in part upon the fact demonstrated by Reid Hunt that it is oxidized in the system with the formation of formic acid, a highly poisonous substance.

Methyl alcohol has been used to some extent in practical medicine, but appears to have no other remedial properties than those of ethyl alcohol, and to be a much more dangerous remedy. It has very properly fallen into complete desuetude in medicine, and under no circumstance should it be employed by pharmacists as a menstruum. The treatment of *methyl alcohol poisoning* is very unsatisfactory. The best that can be done is to aid in the elimination of the alcohol, and of the products of its destruction within the body, by free sweating and by the administration of large quantities of alkalized (sodium bicarbonate) water.

Methyl Chloride.—*Monochlormethane*, CH_3Cl , is obtained by the action of hydrochloric acid gas upon methyl alcohol, best in the presence of a little zinc chloride.

It is a colorless gas, condensing to a liquid at -23°C . (-11.4°F .), and is very soluble in alcohol, which dissolves thirty-five volumes of it, while water dissolves four volumes. On account of its extreme volatility, methyl chloride, when applied in the form of a spray, produces extreme cold and freezing of the part. It has been used in this way as a local anæsthetic. According to Richet

and Marcille (*S. M.*, 1902), methyl chloride acts upon the animal as an efficient anæsthetic, which has practically no influence upon the circulation. Its usefulness seems to be limited by its failure to produce complete muscular relaxation. We know of no clinical reports upon its activity.

Methyl Fluoride. CH_3F .—Henri Moissan (*B. A. M.*, 1890) affirms that this fluoride possesses anæsthetic properties.

Methyl Iodide. CH_3I . *Iodure de Methyl*, Fr. *Jodmethyl*, G.—This is a heavy sweet-smelling liquid, boiling at 43°C . (109.4°F .), and has a sp. gr. of 2.23 at 15°C . (59°F .). In the cold it unites with water to form a crystalline hydrate, $\text{CH}_3\text{I} + \text{H}_2\text{O}$. It turns brown gradually on exposure to light. It is made by the action of dry hydrochloric acid gas upon a mixture of potassium iodide and anhydrous methyl alcohol.

R. Kirk (*L. L.*, Oct. 1885) commends methyl iodide as a vesicant, applied on lint under a watch glass, a drop or two of soda solution being added to neutralize the free iodine that may be present. It produces at once a tingling, burning, biting sensation, like pricking with a number of needle points. The maximum pain is reached in a few minutes, when the substance is to be removed. The blister produced is said to be as full of serum as that caused by cantharides.

Methyl Ether. $(\text{CH}_3)_2\text{O}$. *Methylæ Ether*. *Methyl Oxide*. *Hydrate of Methylene*. *Ether méthylé*, Fr. *Methyläther*, Fr. *Methyläther*, Holzäther, Formäther, G.—This substance was discovered by Dumas and Péligot, but was first employed as an anæsthetic by B. W. Richardson in 1867. He prepares it by mixing one part pure methyl alcohol with two of strong sulphuric acid, heating, collecting and washing repeatedly with potassium hydroxide solution the methyl ether which passes over. It is a gas even at low temperature. Richardson saturates absolute ethyl ether, at 0°C . (32°F .), with it, and at once closely bottles the compound under the name of *methyl-ethylæ ether*. For a detailed description of the preparation of methyl ether and of its properties, see *J. P. C.*, 4e sér., xix. 438. According to Richardson, methyl ether is a very rapid and safe anæsthetic, producing great muscular relaxation with extreme quickness. (*A. J. P.*, Sept. 1870; *Dublin Q. J.*, Aug. 1870; *L. L.*, March, 1870.)

Methylal. *Methylene Dimethyl Ether*. $\text{CH}_2(\text{OCH}_3)_2$.—This is made by distilling methyl alcohol with sulphuric acid in the presence of manganese dioxide, or by abstracting one molecule of water from a mixture of one molecule of formaldehyde and two of methyl alcohol. It is a limpid colorless liquid, of sp. gr. 0.855 at 17°C . (62.6°F .), and boils at 42°C . (107.6°F .). It is soluble in water, alcohol, ether, and fatty and ethereal oils. It was originally proposed as an anæsthetic and hypnotic by B. W. Richardson in 1868. Richardson, Motrokhin, and Personalì are in general accord as to its physiological action. It produces in man a sleep closely resembling the normal sleep; or, if the dose has been large enough, a profound coma in which reflex actions are suspended. Recovery is rapid on account of its rapid elimination. The arterial pressure is reduced, as is also, according to Motrokhin, the irritability of the cerebral cortex. Both Personalì and Motrokhin found that it arrests the tetanic spasms produced by small doses of strychnine, although in Motrokhin's experiments, when large doses of strychnine were given, methylal seemed to accel-

erate rather than put off death. It is employed as an hypnotic, and is said to be free from danger and unpleasant effects; but in most cases patients become so rapidly accustomed to it that its influence soon disappears, unless enormous doses are used. The dose of methylal is from one to two fluidrachms (3.75–7.5 Cc.), given in emulsion.

Methylethylcarbinol. $\begin{cases} \text{CH}_3 \\ \text{CH.OH} \\ \text{C}_2\text{H}_5 \end{cases}$

There are two compounds known respectively as *methylethylcarbinol* and *trimethylcarbinol*. The former is a strong-smelling liquid, boiling at from 98° to 100°C . (208.4° – 212°F .); the latter crystallizes in plates melting at 28°C . (82.4°F .) and boils at from 83° to 84°C . (181.4° – 183.2°F .). These alcohols are said to be vasomotor depressants and antipyretics, the dimethylethyl compound being the more powerful of the two. (*Ph. Post*, Jan. 1888.)

Methylphosphin.—Fürbringer (*Deutsch. Arch. f. klin. Med.*, lix. 1897) has found that this substance is a powerful convulsant poison, killing when in sufficient dose by respiratory paralysis, and having very little direct influence upon the circulation. The *di-methylphosphin* was found to be very slightly more poisonous than the methylphosphin, the fatal dose being about 0.5 gramme per kilo for the rabbit. Di-methylphosphin has been used in malaria by Julius Mannaberg, in the dose of nineteen grains (1.2 Gm.) per day, but is inferior to quinine. The urine becomes dark reddish-yellow and distinctly fluorescent, while numerous small yellow spots appear upon the skin.

Methylthebaine. $\text{C}_{20}\text{H}_{33}\text{NO}_3$.—This product from thebaine has been physiologically investigated by Crum Brown and Fraser, and by Stockman and Dott, and found to have an action similar to that of thebaine, but less powerful. (*B. M. J.*, Jan. 1891.)

Michelia. *Michelia nlagirica*, Zenker. (Fam. Magnoliaceæ).—This tree, which is said to be abundant in the Neigherry hills, India, yields an aromatic, volatile oil, which has entered commerce. (*P. J.*, Jan. 1888.)

Micrapampelis. *Micrapampelis fabacea* (Naud.), Greene. (*Megarrhiza californica*, Torr., *Echinocystis fabacea*, Naud.) *Man Root*. *Big Root*. *Gerba marra*. (Fam. Cucurbitaceæ).—J. P. Heaney has obtained a substance from this root of resinous character which he calls *megarrhizin*, and another which he believes to be a glucoside and calls *megarrhizin*. It is said to be actively cathartic. (*A. J. P.*, 1876, 451.) A second glucoside was obtained by W. M. Young (*A. J. P.*, 1883, 195), to which the name of *megarrhin* was given. It resembles saponin, and possesses the property of dilating the pupil. Young also found two resins, one soluble in alcohol and the other soluble in ether.

Microcidin.—Under this name the varying compounds of sodium naphthalate with other naphthalates and phenates have been put upon the market, and used as a surgical antiseptic, in solution varying from three to eight parts per thousand.

Micromeria. *Micromeria Douglasii*, Benth. *Yerba Buena*.—This labiate of California is said to be a grateful aromatic, and also an anthemintic and an emmenagogue. For description, with figures, see *A. J. P.*, Sept. 1882. Dose of fluidextract, from a half to two fluidrachms (1.8–7.5 Cc.).

Migraine.—A white powder, said by J. Hoffman to be composed of 85 per cent. of antipyrine,

9 per cent. of caffeine, and 6 per cent. of citric acid. It is used in *migraine* and *neuralgia* in doses of fifteen grains (1 Gm.).

Mitchella. *Mitchella repens*, L. *Squaw Vine*. Partridge Berry. Checkerberry. Winter Clover. (Fam. Rubiaceæ).—This small indigenous evergreen has been supposed to possess remedial properties, and is said to be employed, in decoction, by the Indian squaws, to facilitate parturition. It appears to be diuretic, tonic, and astringent, resembling in these respects the pipsissewa, for which it is often substituted. E. Breneiser (A. J. P., 1887, 228) found it to contain some resin, wax, mucilage, dextrin, and what appeared to be saponin.

Mixture of Magnesia and Asafetida. *Mixture Magnesiæ et Asafetidæ*, U. S. 1880. *Mixture de Magnésie et d'Asafétide*, Fr. *Magnesia und Stinkasant-Miatur*, G.—This preparation, which has had some popular vogue under the name of *Devees's Carminative*, was directed by the U. S. Pharmacopœia of 1880 to be made as follows: "Carbonate of Magnesium, five parts [or three hundred and sixty grains]; Tincture of Asafetida, seven parts [or ten fluidrachms]; Tincture of Opium, one part [or seventy-five minims]; Sugar, ten parts [or one and a half ounces av.]; Distilled Water, a sufficient quantity, to make one hundred parts [or fifteen fluidounces]. Rub the Carbonate of Magnesium and Sugar, in a mortar, with the Tincture of Asafetida and Tincture of Opium. Then gradually add enough Distilled Water to make the mixture weigh one hundred parts [or measure fifteen fluidounces]." There is but 1 per cent. of tincture of opium in the formula just given, while the usual quantity is 3 per cent. The dose is twenty minims (1.3 Cc.).

Mollin is a base for ointments that has attracted some dermatological notice in Germany. It is a soft soap, containing 17 per cent. of uncombined fat, and is stated to be prepared by saponifying without heat 100 parts of cocoa-nut oil or of fresh fat with 40 parts of solution of caustic potash, sp. gr. 1.145, mixing intimately with 30 parts of glycerin, and heating carefully. It is yellowish white, of a smooth and soft consistence, not readily altered by exposure, free from rancidity, and easily removed from the skin by warm or cold water.

Momordica. *Momordica Balsamina*, L. *Balsam Apple*. *Balsamina*. (Fam. Cucurbitaceæ).—An annual climbing East Indian plant, cultivated in our gardens for the sake of the ornamental fruit. This is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or orange-yellow color, easily falling when touched, and spontaneously separating into several pieces. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to chapped hands, burns, piles, *prolapsus ani*, etc.; and the mashed fruit is sometimes used as a poultice. According to Descourtiz, two or three drachms taken internally will kill a dog. An extract prepared from it is said to be useful in *dropsy*. Dose, six to fifteen grains (0.4–1.0 Gm.).

Monarda. *Monarda punctata*, L. *Horsemint*. *Menthe de Cheval*, Fr. *Pferdemünze*, G.—This is an indigenous perennial or biennial labiate, growing in light gravelly or sandy soils from New York to Louisiana and west to Wisconsin. The whole herb is employed. It has an aromatic odor, and a warm, pungent, bitterish taste, and abounds in a volatile oil, which may be separated by dis-

tillation with water. Herman J. M. Schroeter (A. J. P., 1888, 120) found the oil to consist of a hydrocarbon, $C_{10}H_{18}$ (56 per cent.), thymol, $C_{10}H_{14}O$ (25 per cent.), and higher oxygenated compounds, $C_{10}H_{18}O$. Kremers (Ph. Rev., 1896, 223) examined the oil from authentic specimens and found it to yield from 56 to 61 per cent. of a phenol (thymol). Horsemint is stimulant and carminative, but is seldom used in regular practice. In the state of infusion it is occasionally employed in families as a remedy for flatulent colic and sick stomach, and for other purposes to which the aromatic herbs are applied. *Monarda fistulosa*, L., *wild bergamot*, *Oswego tea*, an active diuretic (see Proc. A. Ph. A., 1895, 256; 1896, 238), contains, according to J. W. Brandel and E. Kremers, hydrothymoquinone, thymoquinone, besides cymene, carvacrol and limonene (Ph. Rev., 19). The oil of *Monarda citriodora*, Cerv., or *prairie bergamot*, according to Brandel (P. J., 53, 547), contains 65 per cent. of a phenol and 1.2 per cent. citral. For the composition of monarda oils see Ph. Archiv., 1899, 73.

Monesia.—A South American vegetable extract, which is believed to be derived from the bark of *Lucuma glycyphlœa*, Mart. and Eichl. (*Chrysophyllum glycyphlœum*, Casar) (Fam. Guttifera), a tree of moderate size, growing in the forests near Rio Janeiro and elsewhere in Brazil. (J. P. C., 3e sér., vi. 63.) The bark, which has also entered commerce, is in pieces, some of which are three or four lines thick, is very compact and heavy, of a deep brown or chocolate color, contrasting strongly with the grayish color of the epidermis when this remains, and of smooth fracture. The extract was received from South America in cakes weighing rather more than a pound, from three-quarters of an inch to an inch in thickness, of a dark brown almost black color, very brittle, of a fracture neither very dull nor very shining, and of a taste at first sweet, then astringent, and ultimately acrid, the acrimony being very persistent, and especially felt in the fauces. It is entirely soluble in water. The bark was found by Derosne, Henry, and Payen to contain, in one hundred parts, 1.2 of stearin, chlorophyll, and wax, 1.4 of glycyrrhizin, 4.7 of an acrid principle analogous to saponin, called monesin, 7.5 of tannic acid, 9.2 of a red coloring substance, 1.3 of malic acid and calcium malate, 3.0 of various salts, including silica, ferric oxide, and manganese, and 71.7 of pectic acid or pectin and of lignin, including loss, besides traces of an aromatic principle and of gum. A more recent analysis by Peckolt (A. J. P., 1884, 626) gives *monesiatic acid*, which gives a black coloration with iron salts, gallic acid, *monesin*, an acrid, amorphous body, *luoumin*, a body crystallizing in silky needles, a bitter substance, glycyrrhizin, tartaric and citric acids, wax, etc. *Monesin*, which is now considered as identical with saponin, $C_{32}H_{54}O_{18}$, was obtained by treating the bark or extract with alcohol, adding to the tincture an excess of calcium hydroxide in fine powder, filtering, evaporating the clear liquor to dryness, treating the residue with water and animal charcoal, filtering, and again evaporating to dryness. Thus procured it was in transparent yellowish scales, which were easily pulverized, forming a white powder. It was uncrystallizable, readily soluble in alcohol and water, to the latter of which it gave the property of frothing, and insoluble in ether. It had no power to saturate acids, was without odor, but had a slightly bitterish taste, followed by a de-

cided and permanent acrimony in the posterior mouth and fauces. *Monesia* owes its activity probably to this principle and to tannic acid.

Monesia is stomachic and feebly astringent, and has been used with asserted advantage in *diarrhœa*, *hæmoptysis*, *menorrhagia*, *scrofula*, *scurvy*, also as a local remedy in *leucorrhœa*, *ulcerations of the mouth and fauces*, and *ulcers*. It is applied to ulcers either by being sprinkled in powder upon the surface or in the form of ointment made with one part of the extract and seven parts of simple ointment. The *dose* of the extract is from two to ten grains (0.13–0.65 Gm.), repeated every one to three hours. *Monesin* has been given internally in the *dose* of about half a grain (0.032 Gm.), and has also been applied to ulcers. It is said to be a powerful oxytocic, but it is seldom used.

Mongumo Bark.—For analysis of this Madagascar bark, which is said by E. M. Holmes to resemble the bark of *Ochrosia borbonica*, see *P. J.*, ix. 816. It was examined by Dragendorff, who found *mongumic acid*, resin, waxy substance, a glucoside soluble in water and alcohol, metarabic acid, fatty matter, calcium oxalate and a substance insoluble in alcohol and soluble in water.

Monsonia.—According to John Maberly (*L. L.*, Feb. 1897; July, 1898), certain South African plants belonging to the family of Geraniaceæ, having large fleshy roots, are valuable remedies in the treatment both of acute and chronic *dysentery*; such are especially *Monsonia ovata*, Cav., and *M. burkeana*, Planch., ex. Harv. and Lond.; also certain *Pelargoniums*. Under the name of *t'Nanie*, the natives of Namaqualand are said to use the root of *Pelargonium antidysentericum*, Kostel. Maberly believes that the *Pelargoniums* are especially valuable in ulceration of the stomach and upper portions of the intestinal tract, and the *Monsonias* when the disease is low down in the intestines. The *dose* of *monsonia* is given as half an ounce (15.5 Gm.). It is believed that the plants are not poisonous. *Dose* of the saturated tincture from one to two fluidrachms (3.75–7.5 Cc.) every three or four hours.

Morindin.—This principle, discovered by Anderson in *Morinda tinctoria*, Roxb. (*M. citrifolia*, Hunt., not L.), or *Indian mulberry* (Fam. Rubiaceæ), and supposed to be identical with ruberythric acid, is said to be distinct. (*P. J.*, Dec. 1886.)

Moringa. *Moringa pterygosperma*, Gaertn. *Horseradish Tree*. (Fam. Moringaceæ.)—A decoction of the root of this Jamaica tree is said to be used by the peasantry as an active and persistent diuretic. (*The Satellite*, Feb. 1890.)

Morphigenin.—This nitrogenated derivative of morphine, made by E. Vahlen, has been obtained by him only in solution in the form of morphig-

enin hydrochloride, $\text{C}_6\text{H}_5=\text{C}.\text{NH}_2\text{HCl}$. It is said to possess distinct narcotic properties (*A. E. P.*, xlvii. p. 368).

Mountain Green or Mineral Green.—A pigment obtained by powdering green *malachite* or *copper oxycarbonate*, artificially prepared.

Moxa. *Moxa*, Fr. *Brenncylinder*, G.—These are small combustible masses used to produce an eschar by being burned in contact with the skin. In Japan and China they are made from the leaves or the downy hairs on the leaves and stems of one or more species of *Artemisia*. *A. chinensis*, L., and *A. indica*, Willd. (*A. vulgaris*, L.), were

indicated by the Dublin College; but Lindley states that it is the *A. moxa* of De Candolle which is employed. A similar *moxa* has been made in France, by a similar process, from the leaves of *A. vulgaris*. According to Percy, the dried stem of the ordinary sunflower may be used for *moxa*. Artificial *moxas* may be made by the following process: One pound of cotton is introduced into a vessel containing two ounces of nitre dissolved in half a gallon of water, and a moderate heat applied till all the liquid is evaporated. The cotton, when perfectly dry, is formed into thin, narrow sheets, which are rolled round a central cord of linen, so as to form a cylinder from half an inch to an inch in diameter, and several inches long. This is enclosed in a covering of silk or linen sewed firmly around it; and, when used, may be cut by a razor into transverse slices a few lines in thickness. By leaving a hole in the centre of the cylinder, the combustion will be rendered more vigorous, and a deeper eschar produced. Lime, in the act of slaking, has been used as a substitute for the *moxa*. (*Dublin Q. J.*, Jan. 1842.)

Cauterization by fire has been used from time immemorial among savages, half-civilized, and intelligent communities, and is said to have been reintroduced into Europe by the early Portuguese navigators from the Far East. Though at one time much employed for the purposes of revulsion, this form of cauterization has fallen into complete disuse. The curious reader may find the details of its application described in the 18th ed. *U. S. D.* The first sensation experienced is not disagreeable; but the operation becomes gradually more painful, and towards the close is for a short time very severe. The pain could probably be prevented by the use of cocaine.

Muawin Bark.—This is the bark of a Mozambique tree, which in Eastern Africa is used as an ordeal poison. In appearance and structure it closely resembles the *Erythrophloeum* bark. An alkaloid, *muawine*, was discovered in it by E. Merck, 1891. So far it has been obtained only in the form of a thick, syrupy liquid, easily soluble in alcohol, ether and chloroform. The characteristic test is said to be that with vanadinsulphuric acid, which gives with muawine first a pale green, passing into a pale blue. (H. Jacobsohn, *In. Dis.*, Dorpat, 1892; see also *Merck's Jahresbericht*, 1891.) According to Jacobsohn, the hydrobromide when injected subcutaneously does not cause any irritation, but produces in frogs symptoms similar to those caused by digitalin, and in warm blooded animals slowing of the pulse, increase of the heart action, elevation of blood pressure, and contraction of the arterioles. The action of muawine is, therefore, like that of digitalin, but is distinguished by being very temporary.

Mucuna. *Mucuna pruriens* (L.), De Cand. *Dolichos pruriens*, L. *Stizolobium pruriens*, Medic. *Cowhage*. *Cowage*. *Seta Siliquæ Hirsutæ*. *Pois velus*, *Pois à gratter*, Fr. *Kratzbohnen*, *Kuhkrätze*, G.—This is a leguminous climbing plant which grows in the West Indies and tropical America. The East Indian plant, which was formerly considered identical with it, is a distinct species, *M. prurita*, Hook. The fruit is a coriaceous pod, shaped like the Italic letter *f*, about four inches long, and covered with brown bristly hairs, which easily separate, and when handled stick in the fingers, producing an intense itching sensation.

The spicula are said to be very destructive to the round worm, acting mechanically by penetrating their bodies. Neither the tincture nor the decoction is effective. Cowhage is efficient, but so disagreeable that it has passed out of vogue. The usual mode of preparing it is to dip the pods into syrup or molasses, and scrape off the hairs with the liquid, which is in a proper state for administration when it has attained the consistence of thick honey. The dose of this preparation is a tablespoonful (15 Cc.) for an adult, a teaspoonful (3.75 Cc.) for a child three or four years old, to be given every morning for three days, and then followed by a brisk cathartic.

Maira-Puama.—The wood of a Brazilian tree, believed to be from *Dulacia ovata* (Miers), Kze. (*Liriosma ovata*, Miers) (Fam. Olacaceæ), which, according to Th. Peckolt, contains an alkaloid, *maira-puamine*, and is used by the Brazilian aborigines as an aphrodisiac, also in the treatment of dysentery. In impotence, ten to twenty minims (0.6-1.3 Cc.) of the fluidextract may be taken three or four times a day. (See *M. R.*, 1902.)

Mulberry.—There are in the United States three species,—the indigenous *Morus rubra*, L., with red fruit; *M. alba*, L., originally from China, and at one time extensively cultivated as a source of food for the silk worm, having a white fruit; and *M. nigra*, L., a tree of middle size, supposed to have been brought originally from Persia into Italy and thence spread over Europe and America. The fruit of the last species has a sweet, mucilaginous, acidulous taste, and abounds in a deep red juice having the sp. gr. 1.060. (*Mori Succus*, Br. 1885.) In an analysis made by H. Van Hees, 100 parts of mulberries yielded the following percentage results: glucose and uncrystallizable sugar, 9.19; free acid (supposed to be malic with admixture of tartaric), 1.86; albuminous matter, 0.39; pectic matter, fats, salts, and gum, 2.03; ash, 0.57; insoluble matters (the seeds, pectose, cellulose, etc.), 1.25; water, 84.71. In amount of grape sugar the mulberry is surpassed only by the cherry, 10.79, and the grape, from 10.6 to 19.0. Mulberries are refreshing and laxative, and serve to prepare a grateful drink well adapted to febrile cases.

Murexide. $C_8H_4(NH_4)N_5O_6 + H_2O$.—A fine purple dye-stuff, made by the reaction of nitric acid on uric acid. As resulting from the action of nitric acid on urine, it was supposed by Prout to consist of purpuric acid and ammonia (which belief has been confirmed by further investigation), and hence was named *ammonium purpurate*. It is now made from guano. This is first treated with hydrochloric acid to remove foreign substances, and then with soda to dissolve the uric acid, which is separated by neutralizing the soda with hydrochloric acid. The uric acid is dissolved in nitric acid, the solution is heated, and after it cools ammonia or its carbonate is added, which develops the purple color. Murexide is obtained in crystals, which have a square form, and are a rich green color by reflected, but of a purple-red by transmitted light. They are slightly soluble in cold water, more so in boiling water, and insoluble in alcohol and ether. With potassium hydroxide they form a rich purple solution. It has been replaced as a dye by aniline colors.

Muscari. *Muscari comosum*, Mill. (*Hyacinthus comosus*, L.) (Fam. Liliaceæ).—In the bulbs of this plant Curci (*Rép. de Pharm.*, March, 1889) has found *comosic acid*, which he believes to act physiologically like saponin.

Musculus. *Musculus venenosus*.—That certain mussels, or that mussels in certain condition, are actively poisonous is well ascertained. F. Crumpe (*Dublin Q. J.*, Oct. 1873) has reported collapse with complete paralysis of the voluntary muscles as produced by the mussel, and has also treated traumatic tetanus successfully with raw mussels. M. Brieger (*D. M. W.*) has isolated certain bases out of mussels. He thinks the most important is *mytilotoxine* ($C_8H_{15}NO_2$), which he has demonstrated to possess physiological properties closely resembling those of curare. These poisonous principles are all probably ptomaines, and disappear when the mussel is boiled with sodium carbonate; so that boiling the mussel in an alkaline solution (three and a half grammes per liter of water) renders it harmless.

Mushrooms and Toadstools. (*Edible and Poisonous Fungi*).—Notwithstanding the fact that it has been shown that edible fungi, when compared with other articles of food, do not possess a high food value, the interest in the study of the fungi, as well as the consumption of edible forms, is constantly increasing. The study of the fungi is one of the most highly specialized, as there have been up to the present time no less than 39,000 species described. From a food standpoint the differentiation of the edible from the poisonous is one of the most difficult; that the novice can undertake, as it is almost impossible to lay down any invariable rules.

The fungi are divided into a number of classes, each of which is again subdivided into sub-classes, series, and families. The family Hymenomyces (consisting of more than 8000 species) includes all of the mushrooms and toadstools. It is commonly believed that mushrooms are edible and that toadstools are poisonous; in reality, however, no such distinction should be made. The plants of the Hymenomyces are characterized in general in that they arise from a mass of colorless threads, known as "mycelium" or "spawn," produced in the ground, bark of trees, etc. Their first appearance above ground is marked by the production of small solid balls (called buttons), which gradually enlarge, and at length shoot up into a stem or stipe bearing at its summit the umbrella top or "pileus," which is at first closed around the stalk like a closed umbrella and then expands more or less widely, according to the species. The under side of the pileus is the part which bears the spores, which correspond to the seeds of higher plants. In some cases the under surface consists of a series of gills resembling knife blades, which radiate from the top of the stalk to the circumference, like the spokes of a wheel, as in Agaricaceæ; in others it consists of a mass of small pores or tubes packed closely together, side by side, as in Polyporaceæ; in others of teeth, as in Hydniaceæ; in others only slightly wrinkled or undulated, as in Thelephoraceæ, etc. The Hymenomyces are divided into six orders, viz.:

1.—**Agaricaceæ** (the mushrooms and toadstools proper) comprises about 4600 species, some of which are poisonous, as the *Amanitas* (Fly Mushrooms), *Lactarius* (with a milky juice), whereas others are edible, as *Agaricus* (*Psalliota*) *campestris*, L., the common mushroom, *Cantharellus cibarius*, Fr., etc.

2.—**Polyporaceæ** (Pore-Fungi) includes about 2000 species, many of which are parasites on trees and destructive to timber; some are edible, as *Boletus edulis*, Bull., whereas others are poisonous, as *B. satana*, Lenz.

3.—*Hydnaceæ* (Teeth-bearing Fungi); most of the species are too small and woody to be eaten. *Hydnum repandum*, L., forms "fairy rings" in woods.

4.—*Telephoraceæ*; most of the species are small, and the larger species are tough and leathery.

5.—*Clavariaceæ* (Coral-shaped Fungi) includes some large fungi; none are poisonous and some, as *Clavaria flava*, Schaff., are palatable.

6.—*Tomentellaceæ* are the simplest of the Hymenomycetes. They generally form leathery coverings on bark and wood and some are parasites.

The Common Mushroom (*Agaricus campestris*, L.) is practically the only species cultivated in this country, and is the only fresh species sold in the Northern markets during the winter months. It is found wild in open grassy fields or pastures in great abundance in August and September. It is not common in the mountains, never found in woods, and never grows on trees or fallen trunks. The color of the stalk and pileus varies from whitish to a shade of drab, but the color of the gills, a point which must never be overlooked, is at first pinkish and then a brownish purple. This color is due to the spores, which are borne on the gills. The stalk is cylindrical and solid, and has, rather more than half way up, a membranous collar called the ring; but there is no membrane or scales found at the base of the stalk, which appears to come directly out of the ground. "In specimens which are not fully expanded there is a thin membrane or veil which extends from the stalk to the margin of the pileus. When the veil is ruptured, exposing the gills behind, a part remains attached to the stalk, forming the ring already referred to. In older specimens the ring shrinks, but generally a mark remains showing where it has been attached." Two of the most common poisonous forms resembling the common mushroom, and which have been eaten by mistake for it, are the deadly agaric and the fly agaric.

The Fly Agaric (*Amanita muscaria* (L.), Pers.), so called because decoctions have been used for killing flies, is in some localities much more abundant than the common mushroom. It is seldom found in the grassy pastures preferred by the common mushroom, but more generally in poor soil, especially in groves of coniferous trees. "It grows singly and not in groups, and differs from the common mushroom in having gills which are always white, never pink or purple, and in having a hollow stem, which is bulbous at the base and clothed with irregular fringy scales on all the lower part. The pileus varies in color from a brilliant yellow to orange and a deep red, the yellow and orange being more frequent than the red. The surface is polished and has scattered over it a larger or smaller number of prominent, angular, warty scales, which can be easily scraped off. The gills and stalks are white, and there is a large membranous collar which hangs down from the upper part of the stem."

The Deadly Agaric (*Amanita phalloides* (Pers.), Fr.), so named because it probably has been more frequently the cause of death than any other fungus, prefers a damper and less sandy soil than the fly agaric and is not pre-eminently an inhabitant of grassy pastures. "The pileus is often a shining white, but may be of any shade from a dull yellow to olive, and when wet is more slimy than the common mushroom or the fly agaric. It has no distinct scales and only occasionally a

few membranous patches on the pileus. The gills and stalks are white, and the latter has a large ring like the fly agaric and is hollow, or, when young, is loosely filled with cottony threads, which soon disappear. The base of the stalk differs from that of the fly agaric in being more bulbous and in having the upper part of the bulb bordered by a sac-like membrane called the volva. The volva is often of considerable size, but more frequently it is reduced to a membranous rim."

The lists of edible and poisonous fungi are relatively long, and while most belong to the Hymenomycetes, some are also yielded by the Gasteromycetes, as the puff balls. The giant puff ball, *Lycoperdon Bovista*, L. (*L. giganteum*, Batsch) is found in the region of San Francisco Bay, not rarely forty inches in diameter.

It is not possible in this limited space to even mention the various poisonous and edible fungi that experience has demonstrated are such. The number of species which have been eaten or experimented with, however, is small compared to the number of species recognized by botanists. Many students of fungi have formulated rules for distinguishing the edible from the poisonous fungi. "The different popular tests for distinguishing edible from poisonous fungi, such as, for instance, the blackening of a silver coin or spoon when placed in a mass of poisonous fungi while they are being cooked, are all absolutely worthless." The following rules, given by W. G. Farlow, should not be neglected by the beginner:

1.—Avoid fungi when in the button or unexpanded stage; also those in which the flesh has begun to decay, even if only slightly.

2.—Avoid all fungi which have stalks with a swollen base surrounded by a sac-like or scaly envelope, especially if the gills are white.

3.—Avoid fungi having a milky juice, unless the milk is reddish.

4.—Avoid fungi in which the cap, or pileus, is thin in proportion to the gills and in which the gills are nearly all of equal length, especially if the pileus is bright colored.

5.—Avoid all tube-bearing fungi in which the flesh changes color when cut or broken, or when the mouths of the tubes are reddish, and in the case of other tube-bearing fungi experiment with caution.

6.—Fungi which have a sort of spider-web or flocculent ring round the upper part of the stalk should in general be avoided.

Rules 1, 2, and 5 may, for the beginner, be regarded as absolute, with the exception to Rule 2, *Amanita cæsaræa* (Scop.) Kaiserling, the gills of which are yellow. Rules 3, 4, and 6 have more numerous exceptions; but these rules should be followed in all cases, unless the collector is content to experiment first with very small quantities and learn the practical result.

The poisonous mushrooms are divided by R. Robert (*Ueber Pilzvergiftung*, Dorpat, Nov. 1891) into four groups. The first group comprises those fungi which contain muscarine or some alkaloid allied to it. (See Muscarine, p. 1377.) In this group are included species of the old genus *Agaricus*, especially of the section *Amanitas*. In the second group are fungi containing a milky juice and having the generic name of *Lactarius* or *Galorrhæus*. Some of these species, such as *L. deliciosus*, are stated to be edible, but most of them have in their juice a violently irritant resin, which may produce severe, or even fatal, gastroenteritis.

The third group contains species belonging to the genus *Helvella*, whose juice contains *helvelloic acid*, isolated by Boehm. It is asserted that these fungi, when thoroughly dried, are not poisonous, and that hot water also extracts from them the poisonous acid, so that boiling makes them edible. The chief physiological action of the acid seems to be to destroy the red blood corpuscles, and, probably by such action, to produce vomiting, hæmoglobinuria, jaundice, irritation of the kidneys, etc.

The fourth and most important group of poisonous fungi is that which contains a large number of fungi which resemble edible species. According to the researches of Kobert, the toxic property of these fungi is a toxalbumin, which he has isolated from *Amanita phalloides* and given the name of *phallin*. Ordinarily, poisoning from mushrooms is due to plants of the present group. In many cases the fungi as eaten have tasted well, and no evil result has been apparent for many hours after their ingestion; in some cases for twenty hours. The symptoms have been great prostration and collapse, cold sweat, headache, stupor, amaurosis, delirium often with wild cries, coma, mydriasis, convulsions, marked cyanosis, and not rarely icterus; sometimes there is pronounced urticaria. There are usually distinct fever and rapid feeble pulse, while hæmoglobinuria, methæmoglobinuria, hæmaturia, albuminuria, and even suppression of urine have been noted. After death, post-mortem rigidity is often wanting, the gastro-intestinal tract is violently inflamed, the blood fluid and often escaping from the vessels and staining the tissues; while the liver, the heart, the diaphragm, and the muscles have been found in a state of fatty degeneration. The treatment of the poisoning consists in the immediate emptying of the alimentary canal by emetics, castor oil, and cathartics, and the meeting of symptoms as they arise.

B. W. Richardson, having noticed that the smoke of the *Lycoperdon Proteus* or puff ball was used for stupefying bees, found that the inhalation of the fumes caused various animals to become insensible. He has himself inhaled the fumes clarified by passing them through water, and experienced symptoms of intoxication and drowsiness. (*M. T. G.*, 1853, 610.) Thornton Herapath, however, maintains, as the result of his experiments, that these anæsthetic effects are in reality not owing to any narcotic principle present in the fungus, but to the carbon dioxide gas generated during their combustion. (*Philos. Mag.*, July, 1855.)

Musk, Artificial. *Moschus Factitius*.—The artificial musk introduced within recent years as a patented preparation, called "*Musk Baur*," from the name of the discoverer, A. Baur, is *trinitrobutyltoluene*, $C(CH_3)_3C_6H(NO_2)_3CH_3$. It is prepared by adding tertiary butyltoluene slowly in the cold to five times its weight of a mixture of concentrated nitric and sulphuric acids, and afterwards heating the mixture for from eight to nine hours on a water bath. It crystallizes from alcohol in yellowish-white needles, melts at from 96° to 97° C. (204.8°–206.6° F.), and is insoluble in water. It is, however, soluble in alcohol, ether benzene, chloroform, and petroleum benzine.

Artificial musk is an antispasmodic and nervine, which has been highly commended in *spasm of the glottis* of children. *Dose*, ten grains (0.65 Gm.); for a child two years old, from half a grain to a grain (0.032–0.065 Gm.), every two or three hours.

Mutisia. *Mutisia viciifolia*, Cav.—This composite, a native of Chile, is stated to be a valuable anti-spasmodic, useful in hysteria and croup; it is also a cardiac tonic.

Mydrine. *Mydrin*.—A colorless powder, composed of 100 parts of *ephedrine*, the active principle of a Japanese gnetaceous plant, or "*species of Ephedra*," and 1 part of homatropine. It is easily soluble in water, is employed in 10 per cent. solution, and is said to be a useful evanescent mydriatic.

Mydrol. *Iodo-methyl-phenyl-pyrazolon*.—A colorless, inodorous powder of bitter taste, easily soluble in water and alcohol. It is used as a mydriatic in 5 and 10 per cent. solutions.

Myrcia. *Myrcia acris*, Swartz; De Cand., *Prodrom.*, v. 243; Curtis's *Bot. Mag.*, 2d. ser., vol. vi. pl. 3153.—*Myrtus acris*, Willd., *Sp. Plant.*, p. 973. The bayberry, as it is sometimes called, is a tree of considerable size, with a straight stem and a thick pyramidal summit. The young branches are green and sharply four-angled. The leaves are opposite, from 3 to 5 inches long, very coriaceous, lanceolate, obtuse, wavy, somewhat revolute at the edges, with numerous parallel nerves, reticulated on the upper surface, and sprinkled with pellucid dots. They have a very fragrant odor, and are somewhat astringent. The flowers, which are arranged in pedunculate, axillary panicles, longer than the leaves, are small, and white with a reddish tinge. The aromatic berries are round, about as large as a pea, with seven or eight seeds.

The tree is a native of Jamaica and other West India islands. The spirit is probably prepared by distilling rum from the leaves; but we are without precise information on the subject, and it is not impossible that the leaves of other species may also be used. Indeed, an odor of pimenta which it appears to us may be sometimes detected suggests the idea that the leaves of this tree may be at least occasionally added to those of the bayberry. A volatile oil is also obtained from the leaves by distillation, and was official in 1890. (See *Oil of Myrcia*.)

Myrica. *Myrica cerifera*, L. Wax Myrtle. Bayberry. *Candle Berry*. *Arbre à suif*, Fr. *Wachsbäum*, *Wachsgagel*, G.—This is an indigenous myrtaceous shrub growing in great abundance in the sandy soil along the sea shore, and even on the shores of our northern lakes. The leaves of the wax-myrtle have resinous dots on both sides, and are very fragrant when rubbed. The fruit is covered with a coating of white wax, and sometimes continues on the plant for two years or more. The coating of wax upon the surface is collected, and known in commerce as *myrtle wax*. (See *Vegetable Wax*.) A volatile oil might probably be obtained by distillation from the leaves. The bark of the stem and root is supposed to possess valuable remedial properties, and has been employed to a considerable extent. In the dried state it is in quilled pieces of variable length, covered with a thin epidermis of a grayish color somewhat mottled, and marked with slight circular fissures. Within the epidermis the color is reddish brown. The bark is brittle, and of a peculiar, astringent, bitterish, and pungent taste, followed by a slight sense of acrimony. Its powder has a peculiar aromatic odor, and irritates the nostrils and throat when inhaled. It yields its virtues to water and alcohol. George M. Ham-bright found in it volatile oil, starch, lignin, gum, albumen, extractive, a red coloring substance,

tannic and gallic acids, an acrid resin soluble in alcohol and ether, an astringent resin soluble in alcohol and not in ether, and a peculiar acrid principle having acid properties. (A. J. P., 1863, 193.) Myrtle wax consists of the glycerides of stearic, palmitic, and myristic acids and a small quantity of oleic acid (Lewkowitsch, *Oils, Fats, and Waxes*, p. 542). The bark appears to be moderately tonic and astringent, and in large doses emetic. It has been considerably used by the eclectics in *diarrhoea*, *jaundice*, *scrofula*, etc. Externally the powdered bark is used as a stimulant to indolent ulcers, and the decoction as a gargle and injection in chronic inflammation of the throat, *leucorrhoea*, etc. Dose of the powder, twenty or thirty grains (1.3–2.0 Gm.), of a decoction (one ounce to one pint), one or two fluid-ounces (30–60 Cc.). An alcoholic extract, very inappropriately named *myricin*, is given in the medium dose of about five grains (0.32 Gm.).

From the bark of *Myrica Nagi*, Thunb., the yellow coloring matter of which is known as *myricetin*, A. G. Perkin has separated a new glucoside, *myricetrin*, closely resembling *quercitrin*. (See *Proc. Chem. Soc.*, xviii. 11.) (For analysis of the rhizome of the allied *Comptonia peregrina* (L.), Coulter (*Myrica asplenifolia*, L.), see A. J. P., 1892, 303.)

Myrobalans. *Myrobalanum*, Br. Add. *Myrobalani*. *Myrobalans*, Fr. *Myrobalanen*, G.—Five varieties of these East India fruits are distinguished by authors. 1. *Myrobalani bellerica*. These are obtained from *Buceras Bellerica* (Gaertn.), Lyons, (*Myrobalanus Bellerica*, Gaertn., *Terminalia Bellerica*, Roxb.). They are roundish or ovate, from the size of a hazel-nut to that of a walnut, of a grayish-brown color, smooth, marked with five longitudinal ribs, and sometimes furnished with a short, thick footstalk. They consist of an exterior, firm, resinous, brown, fleshy portion, and an interior kernel which is light brown, inodorous, and of a bitterish very astringent taste. 2. *Myrobalani chebulæ*. This variety, which is recognized by the Br. Add., is produced by *Buceras Chebula* (Retz.), Lyons (*Terminalia Chebula*, Willd.) (considered by some to be identical with *B. Bellerica*). The fruit is oblong, pointed at each extremity, from fifteen to eighteen lines in length, of a dark brown color, smooth and shining, with five longitudinal wrinkles, but without footstalks. In their internal arrangement and their taste they resemble the preceding. 3. *Myrobalani citrina vel flavæ*. These are from a variety of the same tree which affords the last-mentioned myrobalans, from which they differ only in being somewhat smaller, of a light brown or yellowish color, and of a taste rather more bitter. They were formerly sometimes sold in the shops of Philadelphia, under the name of *white galls*, to which, however, they bear no other resemblance than in taste. 4. *Myrobalani indica vel nigra*. These are thought to be the unripe fruit of *Buceras Chebula*, or *B. Bellerica*. They are ovate-oblong, from four to eight lines long and from two to three lines thick, of a blackish color, wrinkled longitudinally, and presenting, when broken, a thick brown mass, without kernel, but with a small cavity in the centre. They are sourish and very astringent. 5. *Myrobalani emblicæ*. This variety is wholly different from the preceding, and derived from a plant having no affinity to the *Terminalia*, of the fam. *Combretaceæ*,—namely, the *Phyllanthus Emblica*, L. (Fam. *Euphorbiaceæ*.) It is often in segments, as found in

commerce. When the fruit is entire, it is blackish, spherical depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, and has a strongly astringent and acidulous taste. These fruits were in high repute with the Arabians, and were long employed by European practitioners, as primarily laxative and secondarily astringent, in various complaints, particularly *diarrhoea* and *dysentery*. Their dose was from two drachms to an ounce. Pierre Apéry states that when roasted they are still used in Turkey with excellent results in *intestinal catarrhs*. (R. T., Dec, 1887.) Although the myrobalans are of various origin, they all probably depend for their physiological activity upon the presence of gallo-tannic acid. Procter states that they contain from 30 to 35 per cent. of gallotannic and ellagitannic acids.

Myrobalan ointment (*Unguentum Myrobalani*, Br. Add., one to four) and *myrobalan and opium ointment* (*Unguentum Myrobalani cum Opio*, Br. Add.), are used as local astringents. The internal dose of myrobalans is one-half to one drachm (2.0–3.9 Gm.), given in the form of a powder.

Myrtus. *Myrtus communis*, L. *Common European Myrtle*. (Fam. *Myrtaceæ*.)—The leaves of this plant yield, by distillation, *myrtol*, which is a mixture of a dextro-rotatory terpene, recognized as pinene, cineol, $C_{10}H_{18}O$, which is identical with cajuputol and eucalyptol, and dipentene. The mixture usually known as *myrtol* is collected between 160° and 180° C. (320°–356° F.). *Myrtol* has been recommended as an antiseptic and a powerful stimulant to the pulmonic and genitourinary mucous membranes, and useful in chronic *bronchitis*, *cystitis*, or *pyelitis*. Jahns believes that the medicinal activity of the oil depends upon the presence in it of *cineol*. Dose, from one to two minims (0.06–0.13 Cc.), given in capsules, from four to eight times a day. A. de Vevey (R. T., lxiii. 1896) has used the 10 per cent. solution in sterilized olive oil hypodermically in doses of eighty to one hundred and sixty minims (5–10 Cc.) once or twice in twenty-four hours, with asserted very good results in all forms of chronic or bronchial catarrh.

Nabalus. *Nabalus albus* (L.), Hook. (*Prenanthes alba*, L.) *Rattlesnake Root*. *White Lettuce*. *Cancer Weed*. *Gall of the Earth*. *Lion's Foot*.—In certain portions of Virginia and North Carolina, where this perennial herb grows, great value is attached to it in *rattlesnake bite*. The milky juice is taken freely internally, and its leaves steeped in water which is locally applied and frequently changed. The plant is also used in *dysentery*, and N. B. Williams has found tannin in the rhizome. (A. J. P., 1887.)

Nag-Kassar.—This is the anthers of an ornamental tree much cultivated in Southern Asia. (See *Ph. Post*, May, 1888.)

Nance Bark.—This bark is believed to be obtained from the *Malpighia glabra*, L. (Fam. *Malpighiaceæ*); it is much used in Mexico for tanning, and, according to F. Holberg, contains 26.2 per cent. of tannin. (A. J. P., xvi. 239.)

Naphthalan. *Naftalan*.—This is a greenish-black soft mass, prepared by the fractional distillation of naphtha obtained from the Armenian highlands, having a slightly empyreumatic odor, a neutral reaction, and a specific gravity of 0.89. It melts at 70° C. (158° F.), is insoluble in water and glycerin, but mixes readily with fats and oils, and

is soluble in ether and petroleum benzin. It has been recommended by Rosenbaum and others as very efficacious in the treatment of *pruritus* and *burns*, as well as in *chronic eczema*, *syccosis*, and other parasitic skin affections, and as having a range of usefulness closely parallel to that of the oil of cade. It is necessary to apply it in the form of a thick coat to the affected skin and envelop it so as to exclude the air. Stains produced by it on the clothing can be removed by petroleum or benzene. Applied as a paste, 50 per cent. naftalan, .25 per cent. each of zinc oxide and of starch, with or without 2 to 5 per cent. of menthol. (See *Praktitchesky Vrach*, vol. i. No. 31.)

Naphthylaminsulfonic Acid. *Acidum Naphthylaminsulfonicum*. *Naphthionio Acid*.—*Sulphonaphthylaminic acid* ($C_{10}H_7(NH_2)HSO_3$) is a white powder, soluble in about four thousand parts of cold water, which has been proposed by E. Riegler on chemical grounds as an antidote for poisoning by the nitrites and in severe *iodism*. It is eliminated through the kidneys, causing acidity of the urine, and has been recommended in the treatment of chronic *cystitis*. The dose is eight grains (0.5 Gm.), taken with starch in a capsule every three or four hours.

Naples Yellow.—A yellow pigment prepared by calcining a mixture of lead, antimony sulphide, dried alum, and ammonium chloride, or a mixture of lead carbonate, diaphoretic antimony, dried alum, and ammonium chloride. (Gray.)

Narcissus. *Narcissus Pseudonarcissus*, L. *Daffodil*. *Narcisse des prés*, *Porillon*, Fr. *Gelbe Narzisse*, G. (Fam. *Amaryllidaceæ*.)—Both the bulb and the bright yellow flowers of this common garden plant have been used in medicine. The flowers have a feeble peculiar odor, and both have a bitter mucilaginous taste. They are an uncertain emetic. It is probable that the flowers of the wild European plant are more powerful than those of the cultivated. A. W. Gerrard examined the bulbs of daffodil, and obtained a crystalline neutral principle and an amorphous alkaloid, which he calls *pseudonarcissine*. According to Ruiger, the alkaloid obtained by Gerrard from the bulb of the flowering plant dries the mouth, checks perspiration, dilates the pupil, especially when applied locally, quickens the pulse, and acts on the heart of the frog antagonistically to muscarine and pilocarpine, while the alkaloid taken from the bulb after flowering causes salivation and perspiration, internally taken contracts the pupil, and topically applied dilates it slightly. (*J. P.*, i. 436.) In France, *narcissus* flowers have been used as an antispasmodic. The dose of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from twenty grains to two drachms (1.3–7.7 Gm.); while the extract is said to cause vomiting in the dose of two or three grains (0.13–0.20 Gm.). The bulb is most powerful in the recent state.

Narcotile.—This is a colorless, highly volatile, very inflammable liquid, said to be a mixture of methyl and ethyl chlorides, and to be produced by the action of hydrochloric acid on a mixture of ethyl and methyl alcohols. It has been highly recommended as an anæsthetic. (*L. L.*, 1903, 1.)

Nard. *Spikenard*.—Several aromatic roots were known to the ancients under the name of *nardus*, distinguished, according to their origin or place of growth, by the names of *Nardus Indica*, *Nardus Celtica*, *Nardus montana*, etc. They are supposed to have been derived from different valerianaceous

plants. Thus, the *Nardus Indica* is referred to *Nardostachys Jatamansi* (Roxb.), DC. (*Valeriana Jatamansi*, Roxb.), of Bengal, the *Nardus Celtica* to *V. celtica*, L., inhabiting the Alps, Apennines, etc., and the *Nardus montana* to *V. tuberosa*, which grows in the mountains of the south of Europe. The *Indian nard*, or *spikenard*, sometimes also called *Syrian nard*, is still occasionally to be found in commerce. It is a small delicate root, from one to three inches long, beset with a tuft of soft, light brown, slender fibres, of an agreeable odor, and a bitter aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of valerian.

Naregamia, or **Goanese Ipecacuanha**.—The root of *Naregamia alata*, Wight and Arn. (Fam. *Meliaceæ*), of Western India, has been much employed as an emetic, as a hepatic stimulant in *dysentery*, and in small doses as an expectorant in *bronchitis*. Drasche of Vienna, confirms the value of the drug. (*Cb. G. T.*, 1890.) In it Hooker has found an alkaloid, *naregamine*, an oxidizable fixed oil, and a wax. (See *P. J.*, vol. xv. 1887.) The dose of a concentrated tincture (1 to 4) is from five to ten minims (0.3–0.6 Cc.); as an emetic, from fifteen to thirty minims (0.9–1.8 Cc.).

Nargol.—*Nuclein Silver* contains about 10 per cent. of silver and is a light brownish white powder, easily soluble in water. The solutions are not precipitated by albumin, salt, or alkalies. It is used like protargol.

Nasrol. $C_8H_9N_4O_5.SO_3Na$. *Sodium Sulphocaffate*. *Sodium Caffeine Sulphonate*.—*Symphoral-sodium* is an intensely bitter powder recommended as a diuretic in *dropsy*. Dose, 1 grain (0.065 Gm.) given in capsules.

Nasturtium. *Watercress*. *Cresson de fontaine*, Fr. *Brunnenkresse*, G. *Roripa Nasturtium* (L.), Rusby (*Sisymbrium Nasturtium*, L., *Nasturtium officinale*, R. Br.). (Fam. *Cruciferae*.)—In sensible and medicinal properties watercress bears some resemblance to scurvy grass, though milder, and on this account is preferred for the table. It is thought to be useful in *scurbutic affections* and *visceral obstructions*. It contains a volatile oil, which, according to A. W. Hofman, contains as its chief constituent a body boiling at 253° C. (487.4° F.), which he considers to be the nitrile of *phenyl-propionic acid*, $C_9H_{10}O_2$, and therefore has the formula $C_9H_{10}N$. The expressed juice is sometimes given in the dose of one or two fluid-ounces (30–60 Cc.); but the herb is more frequently used in the form of a salad.

Other species of *Roripa* (*Nasturtium*), as *R. palustris* (L.), Bass. (*N. palustre*, DC.), or *marsh watercress*, and *R. amphibium* (L.), Lyons, or *water radish*, grow in similar situations with the *R. Nasturtium*, and act similarly.

Nerium. *Nerium Oleander*, L. *Laurier Rose*, *Laurose*, Fr. *Oleander*, *Rosenlorbeer*, G. (Fam. *Apocynaceæ*.)—The common ornamental shrub known as *oleander* is affirmed to have been used from time immemorial in portions of Southern Europe for destroying rats, and a number of cases of poisoning by it have been reported. For collection, see *T. G.*, July, 1888. The symptoms have been vomiting, abdominal pain with frequent cries, dilatation of the pupil, vertigo, convulsive movements, insensibility, small, very slow pulse, and in fatal cases epileptiform convulsions with coma ending in death. The action on the heart has in some cases in which death

has not ensued, been very pronounced, the pulse for five days remaining as low as forty per minute. The infusion made from four ounces of the root is affirmed to have taken life. M. E. Pelikan (*O. R. A. S.*, 1866, 239) found that in the frog the extract of oleander causes immediate increase in the number of the heart beats, followed after a little by slowing of the cardiac movements, and later by irregularity of contraction, ending in systolic arrest of the ventricles at a time when the auricles continue to beat and the frog is still able to jump about freely. Pelikan's experiments upon dogs have not, we believe, been published in detail, but they led him to the conclusion that the oleander acts in the mammal upon the heart in the same way as does digitalis. He also convinced himself that the active principle was a yellow, resinous principle, insoluble in water, easily soluble in amyl alcohol and chloroform, previously discovered by Latour. (*J. P. C.*, t. xxxii. 32.)

Two supposed alkaloids have been discovered in oleander by Leukowsky (*J. P. C.* (3), 46, 397), one named *pseudocurarine*, the other named *oleandrine*. Both neutralize acids; the former dissolves in water and alcohol, but not in ether, and is neither volatile nor poisonous; the latter is yellow, amorphous, very bitter, very slightly soluble in water but more freely in alcohol and ether, and poisonous in its action on the system. H. G. Greenish isolated two substances, *neriodorin* and *neriodorein*, which are probably not pure proximate principles. (*A. J. P.*, 1881, 350.) B. C. L. Bose (*P. J.*, 1901, 553) obtained a resinous substance, *karabin*, $C_{21}H_{49}O_6$, which he states is one of the active constituents of this plant. Haemel (*Ph. Ztg.*, 1901, 58) obtained a semi-concrete oil to the amount of 0.025 per cent. from the leaves of *N. Oleander*. Dubigadoux and Durieu affirm that they have obtained strophanthin from the oleander of Algeria.

Schmiedeberg (*A. E. P. P.*, 1883, Bd. xvi. 145) finds two active substances in the oleander leaf,—*neriin* and *oleandrin*. Schmiedeberg shows that the latter, which had been previously described by Leukowsky as an alkaloid, is a glucoside, and on boiling with very dilute acids breaks up into sugar and a yellow resinous substance like digitaliresin. With concentrated acids it also decomposes, yielding an inactive resin. Schmiedeberg also obtained from African leaves a glucoside, *nerianthin*, which he surmises to be an educt from oleandrin. He found oleandrin to be a powerful cardiac poison, but nerianthin not to have the power of arresting the frog's heart, although it exerts some influence upon it, possibly, as Schmiedeberg surmises, through contaminating oleandrin. Pieszezek obtained from oleander bark a principle which he named *rosaginin*, which was very poisonous, resembling strychnine in its action (*A. Pharm.*, ccxviii. 352).

Pouloux (*B. G. T.*, May 15, 1888) finds that five centigrammes of the extract of oleander produced in the frog paralysis and death in about forty minutes; that the ventricle is thrown into a state of tetanus which is complete in about five minutes, the auricles continuing to contract for a considerable length of time. The mortal dose for the rabbit he determined to be about fifty centigrammes of the hydro-alcoholic extract. In a few cases of valvular heart disease Pouloux found oleander to do very well, and in seventy-five cases under the care of Freiherr (*Aerzt. Rund.*, 1892) it acted promptly as

a heart stimulant and tonic in cardiac weakness. Its diuretic action is said to be very marked, and not rarely it acts as a cathartic. Any irritation of the alimentary canal contra-indicates its use. Under its influence the pulse rapidly becomes regular and slow, and dyspnoea and oedema disappear. Freiherr asserts that it is safer than digitalis in atheromatous diseases. S. Wateff has reported a case of poisoning by oleander in which the symptoms were vomiting, violent headache, cardiac oppression, cold, blue hands, at first rapid and afterwards very slow, weak pulse, with marked failure of temperature. Freiherr uses it in infusion or tincture, representing as the daily dose from three-quarters to one and a half grains (0.048–0.096 Gm.) of the dried oleander bark, one and a half to three grains (0.096–0.2 Gm.) of the fresh bark, one and a quarter to three and a half grains (0.08–0.23 Gm.) of the dried fruit. Pouloux's dose of the extract was three-quarters of a grain (0.048 Gm.). Orfele has used the dried flowers—dose, three grains (0.2 Gm.) in substance, or from ten to twenty minims (0.5–1.0 Cc.) of a 10 per cent. tincture—with success. The fluidextract would probably be the best preparation.

Nervocidine.—This is a yellow, amorphous, hygroscopic powder, readily soluble in water, which is affirmed to be an alkaloid, obtained from the East Indian plant, *Gasu Basu*, and to be a powerful local anæsthetic, its 1 per cent. solution producing marked anæsthesia of the cornea. It is stated to be so irritant that its 2 per cent. solution will cause in dogs and rabbits an ulcerative keratitis along with an anæsthesia which lasts for days. It is affirmed, further, to be a paralyzing poison, causing such symptoms as to almost invalidate its usefulness and render it unsafe. (*L. L.*, 1902, 1.)

Neurodin. *Acetyl-p-oxy-phenyl-urethane*, $C_6H_4(OCOCH_3)NH.COOC_2H_5$.—Forms colorless, odorless crystals, fusing at 87° C., soluble in 1400 parts of cold water. It is used as an anodyne in neuralgia in doses of from fifteen to twenty grains (1–1.3 Gm.).

Neurolæna. *Neurolæna lobata*, R. Br.—From the leaves of this plant, used in the Windward Islands as a substitute for quinine, and in *dysentery*, B. H. Paul and A. J. Cowley obtained an uncrystallizable alkaloid. (*P. J.*, ix.)

Nickel. *Niccolum*.—T. P. A. Stewart (*A. E. P. P.*, Bd. xviii. 154) finds that in frogs soluble preparations of nickel produce palsy with convulsive movements which are due to an action upon the nerve centres, the muscles remaining intact, the heart also being affected, as it is believed, by an action upon its motor ganglia. In mammals the chief symptoms produced by nickel are paralysis, with motor disturbance bearing some resemblance to chorea, with convulsions and great irritation of the gastrointestinal tract, and a marked fall of the blood pressure, due to paralysis of the vasomotor centre. Large doses of nickel seem, however, to be necessary for a toxic influence, and the use of nickel in culinary instruments appears to be entirely safe. Riché (*B. A. M.*, 1888), as the result of experiments made upon dogs and guinea pigs, reaches the conclusion that nickel is not more poisonous than iron. Thus, a dog absorbed over five drachms of it in sixty days, and increased in weight. The results obtained by Riché have been confirmed in Germany by Von Hamel Roos and by Schulz. (*P. J.*, Dec. 1887.)

Nickel Bromide is a greenish-yellow powder, of a sharp, almost burning taste, freely soluble in water, and making a grass-green solution. It is made by the action of bromine vapor upon the finely divided metal, either by heating the nickel in the vapor, or by the action of the two in the presence of water. It forms deliquescent needles of $\text{NiBr}_2 + 3\text{H}_2\text{O}$. It was first brought forward by J. M. Da Costa as a remedy for *epilepsy* and kindred disorders, and its value has been confirmed by R. Leaman. (*Med. Gaz.*, April 18, 1885.) He affirms that ten grains of the nickel salt are equal to thirty grains of potassium bromide; that it is best used in effervescing form, made by mixing the salt with sodium bicarbonate and tartaric acid and moistening with alcohol and passing the moist powder through a sieve and drying in a warm closet. It has been physiologically investigated by H. A. Hare, who finds (*T. G.*, vol. ii. 297) that it is a powerful paralyzant to the spinal cord, the motor and sensory nerve trunks, and also to the voluntary muscle. In sufficient dose it causes immediate diastolic cardiac arrest. In smaller doses it lessens the arterial pressure by depressing the heart and the vasomotor centres.

Nickel Carbonate. *Niccoli Carbonas. Carbonate Niccolique*, Fr. *Nickelkarbonat*, G.—Made by precipitating the solution of a nickel salt with potassium carbonate. It is from pale green to dark green, of variable composition and is little used, though at one time it was often employed in *anæmia* in doses of two grains (0.13 Gm.).

Nickel Carbonyl. *Carbonic Oxide-Nickel. Nickel-Kohlenoxyd*, G. $\text{Ni}(\text{CO})_4$.—This substance was first investigated by Mond, Lang, and Quincke, who reported to the Société de Biologie, 1890, that it is difficult to handle because its vapors produce excruciating headache, and that it is a violent poison, evidently destroying the hæmoglobin of the blood. A. Mittasch (*A. E. P. P.*, xlix. 367; *L. L.*, 1903, i.) found that the vapors produced febrile reaction with violent disturbances of respiration, followed by great and very persistent malaise and weakness. Langlois (*O. R. S. B.*, 1891), also McKendrick and Snodgrass (*B. M. J.*, June, 1891), have shown that it acts by being broken up in the body and yielding carbon dioxide to the hæmoglobin. It produces prolonged fall of temperature, but it is not probable that it will prove of any practical value in medicine. For physical properties and methods of preparation, see authors already quoted.

Nickel Chloride. *Niccoli Chloridum. Chlorure de Nickel*, Fr. *Nickelchlorür*, G.—A green, very deliquescent salt, containing $6\text{H}_2\text{O}$, 45.4 per cent. of its weight. The anhydrous chloride is yellow and sublines in yellow scales, without melting.

Nickel Sulphate.—*Niccoli Sulphas, NiSO₄.7H₂O*, is formed by dissolving *nickel carbonate* in diluted sulphuric acid, concentrating the solution, and setting it aside to crystallize. The carbonate is procured by dissolving the impure *nickel arsenide*, sold under the name of *speiss*, coarsely powdered and mixed with half its weight of iron filings, in nitrohydrochloric acid. The solution is evaporated to dryness, and the residue treated with water, which takes up the impure nickel chloride, and leaves the arsenic in the form of the insoluble ferric arsenate. The liquid is then acidulated with hydrochloric acid, treated with hydrogen sulphide in excess, which precipitates the copper, and, after filtration, boiled with a little nitric acid to oxidize any remaining iron. The cold liquid, largely

diluted with water, is next treated with a solution of sodium bicarbonate, gradually added, which throws down the iron in the state of ferric oxide. Lastly, the filtered solution, containing the nickel chloride nearly pure, is boiled with sodium carbonate, which, by double decomposition, throws down a pale green precipitate of nickel carbonate. Nickel sulphate is in the form of emerald-green crystals, efflorescent in the air, soluble in three parts of cold water, but insoluble in alcohol and ether. It has a sweet, astringent taste. Simpson of Edinburgh, found this salt to act as a gentle tonic; useful in *migraine* in doses of from half a grain to a grain (0.032–0.065 Gm.) three times a day. In large doses it is liable to produce nausea and vomiting, especially when the stomach is empty. (See *Braithwaite's Retrospect*, xxvii. 446.)

Nicotine Salicylate. *Nicotine Salicylas. C₆H₄(OH)COOH.C₁₀H₁₄N₂*. This substance occurs in colorless crystals, soluble in water and alcohol, fusing at 118° C. (244.4° F.). Under the name of *eudermol* a substance composed chiefly of lanolin, containing 0.1 per cent. nicotine salicylate, has been put upon the market and highly commended for the treatment of *scabies* and other parasitic diseases of the skin, also of *itching eczema*. Ointments containing a larger per cent. are said to be dangerous. (*Th. M.*, 1898.) The application of the ointment should be followed after some hours by a soap bath. L. C. Feticch has used the 1 per cent. lanolin ointment of nicotine salicylate in cases of *mange* of dogs. When the mange is of the acarid variety the treatment should be assisted by baths containing 2 to 4 per cent. of potassium sulphide.

Nigella. *Nigella sativa*, L. Nutmeg-flower. Small Fennel-flower. *Faux Cumin*, Fr. *Schwarzkümmel*, G. (Fam. Ranunculaceæ).—A small annual plant, growing wild in Syria and the south of Europe, and cultivated in various parts of the world. The seeds, *semen nigellæ*, are ovate, somewhat compressed, about a line long and half as broad, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odor, like that of nutmegs, and a spicy, pungent taste. (*P. J.*, 1882, 681.) Their chief constituents are a volatile and a fixed oil (1.5 per cent. of the former and 35 per cent. of the latter), and an amorphous glucoside, *melanthin*, which is decomposed by diluted hydrochloric acid into *melanthigenin* and sugar. The *nigellin* of Reinsch does not seem to have been a pure substance. Rochebrune has found a powerful paralyzing alkaloid, to which he gives the name of *nigelline*. (*Toxicol. Africaine*, vol. i.) Melanthin, according to W. von Schulz, exhibits the typical physiological action of the most poisonous saponins. In India the seeds are considered as stimulant, diaphoretic, and emmenagogue, and are believed to increase the secretion of milk. They are also used as a condiment, and as a corrigent or adjuvant of purgative and tonic medicines.

Nirvanin. *Hydrochloride of diethylglycocoll-p-amid-o-oxybenzoic-methylester*, of the formula:

Nirvanin occurs in white prisms with a melting point of 185° C. (365° F.), affording a violent reaction with ferric chloride, and soluble in water.

Nirvanin has been brought forward as a local anæsthetic, with a claim that it is only about one-tenth as actively toxic as cocaine, and is

as effective as a local anæsthetic. It is also alleged to be actively antiseptic, the 1 per cent. solution effectively preventing the growth of bacteria. The 5 per cent. solution placed in the eye produces a temporary irritation followed by lasting anæsthesia. It has been used to a considerable extent as a substitute for cocaine in infiltration anæsthesia, the strength of the solution used varying from one-tenth to one-third of 1 per cent. Nirvanin has also been used to a considerable extent in dentistry; eight grains (0.5 Gm.) are stated to have been given to an adult, hypodermically, without the production of toxic symptoms. (Elsberg, *Ther. Prog.*, April, 1900.)

Nitrated Alcohols.—The following substances of the possible series of nitrated alcohols have been studied by J. B. Bradbury (*B. M. J.*, ii. 1895);

Methyl Nitrate, CH_3ONO_2 (CH_3NO_3).

Glycol (Ethylene) Dinitrate CH_2ONO_2
 $\text{C}_2\text{H}_4(\text{NO}_3)_2$ CH_2ONO_2

Glycerol Trinitrate (Nitroglycerin) CH_2ONO_2
 $\text{C}_3\text{H}_5(\text{NO}_3)_3$ CH_2ONO_2
 CH_2ONO_2

Erythrol Tetranitrate $(\text{CH}_2\text{ONO}_2)_2$
 $\text{C}_4\text{H}_6(\text{NO}_3)_4$ CH_2ONO_2
 CH_2ONO_2

Arabinol Pentanitate $(\text{CH}_2\text{ONO}_2)_3$
 $\text{C}_5\text{H}_7(\text{NO}_3)_5$ CH_2ONO_2
 CH_2ONO_2

Mannitol Hexanitate $(\text{CH}_2\text{ONO}_2)_4$
 $\text{C}_6\text{H}_8(\text{NO}_3)_6$ CH_2ONO_2

Of the group the first three are liquid. The others are crystalline colorless solids, stable in the dark at a moderately low temperature, turning yellow and exploding when heated rapidly or percussed. Of slight solubility in water, soluble in alcohol and ether, responding when heated to the meta-phenylene diamine test.

Bradbury has shown that all these substances have similar physiological action, differing among themselves and from amyl nitrite simply in the rapidity and fugaciousness of influence. Glycol dinitrate in $\frac{1}{100}$ of a grain (0.0006 Gm.) doses markedly influences arterial tension in the human being, but its effect is not maintained longer than sixteen minutes. Erythrol and mannitol nitrates were found to be slow in action but of remarkable permanence and influence, their effect on the lower animals lasting more than four or five hours. Methyl nitrate was feeble and fugacious in its influence.

Both erythrol and mannitol nitrates have been used by Bradbury in *angina*, *aneurism*, *Raynaud's disease*, *asthma*, *headache*, and various other affections for which nitroglycerin has been employed. Erythrol nitrate, as more soluble, appears to be preferable to mannitol nitrate; it has been used and highly commended by Arthur Burton and others. It may be given in powder or in solution. It is less easily exploded than nitroglycerin, but great care must be practised in any attempt at powdering, as a very serious explosion has occurred from rubbing it in a mortar with sugar of milk. One part of it may be dissolved in sixty parts of alcohol and a fluidrachm of this

taken in an ounce of water every four to six hours. The dose of the 1 per cent. alcoholic solution of mannitol nitrate is one and a half fluidrachms (5.5 Cc.). These solutions are said to be stable.

Nitrobenzene. *Nitrobenzole.* *Oil of Mirbane.* $\text{C}_6\text{H}_5\text{NO}_2$.—Nitrobenzene is formed by the action of strong fuming nitric acid upon benzene,

The product, after having been washed with water, is an oily, yellowish, intensely sweet liquid, with an odor like that of oil of bitter almond. Its density is 1.186, and boiling point 213°C . (415°F). It has become of commercial importance, being produced as an intermediate product in the manufacture of aniline oil, and, under the name of *artificial oil of bitter almonds*, or *oil of mirbane*, being employed for scenting soaps and pomades. Its use in articles of food and for flavoring, as a substitute for bitter almond oil, is properly forbidden under pure food regulation. For method of detecting nitrobenzene in oil of bitter almond, see *Oleum Amygdalæ Amaræ*, p. 829.

In manufactories where nitrobenzene is made, headaches, with sleepiness, are not infrequently produced by inhalation of the fumes; much more serious poisoning is liable to occur, and there have been a number of deaths produced by nitrobenzene. The symptoms may come on almost immediately, or they may be delayed for some hours. According to Filehne (*A. E. P. P.*, Bd. ix.), the slowness of action is chiefly dependent on the fact that nitrobenzene, when mixed with the contents of the stomach and intestines, is absorbed with very great slowness; for if the drug be injected directly into the blood of the rabbit, it produces death in convulsions in less than a minute. The first symptoms of poisoning are headache, with muscular weakness, and a peculiar bluish color of the face, and disturbance of consciousness. In the fully developed poisoning the whole surface of the body is a deep bluish color, and the mucous membranes a bluish gray; the pupils are dilated; the muscular relaxation is complete, except that sometimes the jaw is rigidly set; the consciousness is lost; the respiration is rapid, but shallow and irregular; the pulse rapid and thready, or entirely absent. The urine contains urobilin, indican, and acetone. Recovery may occur, as in a case reported by Stevenson (*Guy's H. R.*, vol. xxi. 1876), after many hours of unconsciousness, the bluishness of the skin and the headache remaining for several hours longer. After death, the blood is of a deep chocolate brown, and, according to Filehne, has lost the power of absorbing oxygen. Lewin has seen the blood so changed that, after five weeks' standing, the oxy-hæmoglobin lines could still be made out, and its spectrum is altered. (See *A. Phys.*, 1879.)

In poisoning of the lower animals convulsions are frequent phenomena, and, according to Letheby (*P. J.*, Sept. 1863), after small doses, the animal sometimes for days will have more or less unconsciousness, with epileptic attacks, and at length die of exhaustion, or gradually recover. In the guinea pig, but not in the dog, Ewald has found nitrobenzene to produce glycosuria. (*P. M. T.*, vol. iv. 312.)

The cause of death appears to be paralysis of the motor nervous centres. Letheby states that nitrobenzene is partly converted in the body into aniline, but this is denied by Filehne, who asserts that the aniline was produced by the processes used by Letheby. According to Caspar,

death from prussic acid and nitrobenzene may be distinguished by the fact that when the body is left open for some hours, the odor of prussic acid leaves, while that of nitrobenzene persists. The minimum fatal dose is not known; according to Taylor, fifteen drops (0.75 Cc.) taken by the mouth, have proved fatal, and in Stevenson's case, twenty-three minims (1.42 Cc.), taken in seven doses, in forty-eight hours produced unconsciousness and respiratory arrest, so that death would probably have occurred if treatment had not been instant.

The proper treatment would appear to be emetics, the early use of artificial respiration, maintenance of the bodily temperature, and the stimulation of the respiration and circulation by hypodermic injections of atropine, strychnine, and digitalis. In a case reported by Werner (*B. K. W.*, 1884, xxi.), life was apparently saved by bleeding sixteen fluidounces (480 Cc.) and transfusing twelve fluidounces (360 Cc.) of defibrinated blood.

Dinitrobenzene. *Dinitrobenzol.* $C_6H_4(NO_2)_2$. On boiling benzene with fuming nitric acid, there is formed chiefly metadinitrobenzene, fusing at $90^\circ C.$ ($194^\circ F.$), with small amounts of the ortho and para compounds. By crystallizing out of alcohol, the meta compound can be obtained pure. Dinitrobenzene has attracted considerable attention on account of the number of cases of poisoning by it occurring among the workmen in aniline works. The symptoms are said to be jaundice, enlargement with tenderness of the liver, diarrhœa with colorless stools, and dark brown urine in which dinitrobenzene can be located by the phenylene-diamine test. The toxicology has been especially studied by Strassmann and Strecker (*Friedreich's Blätt. f. Gerich. Med. u. Sanitätspolizei*, Heft iv. 1896), who add to the symptoms already given, headache, a peculiar bluish discoloration of the face and general surface, a tendency to fainting, with excessive sweating, vomiting, fall of temperature, great muscular weakness, and finally collapse. It is noted also that in animals experimentally poisoned there has been destruction of the red blood corpuscles with consequent hæmoglobinuria and wide-spread fatty degeneration. According to White and Hay (*L. L.*, ii. 1901) pure dinitrobenzene is much less poisonous to the workers than is the commercial dark colored substance which contains mononitrobenzene. Mononitrobenzene is, however, according to the same authority, scarcely poisonous, the reason that the commercial mixture is more poisonous than the pure dinitrobenzene being that the mononitrobenzene is a powerful solvent of dinitrobenzene, making an oily mass which adheres to the skin and yields to absorption the dinitrobenzene. The fact that the dinitrobenzene is absorbed through the skin of the workmen is so generally recognized that in most commercial laboratories the workmen are required to wear specially close fitting clothing over the body and head, and to practise absolute cleanliness.

Nitrogen Monoxide, so-called *Nitrous Oxide*. *Laughing Gas.* *Oxyde nitreux*, *Protoxide d'Azote*, *Fr. Stickstoffoxydul*, *Lachgas*, *G. N₂O*.—These names have been given to a gaseous substance, discovered by Priestley in 1776, but first brought into general notice in 1800 by Humphry Davy, who discovered and made known the remarkable exhilarating properties which earned for it the name of laughing gas.

Preparation.—In its preparation, pure fused ammonium nitrate is submitted in a glass retort to a heat sufficient to decompose it, not exceeding $204.4^\circ C.$ ($400^\circ F.$), and the resulting gas and vapor are collected in a glass receiver over warm water or a saturated aqueous solution of common salt. Warm water is preferred because cold water absorbs much of the gas, and would consequently occasion loss, and even warm water, though it takes up much less, is not entirely unobjectionable on this score; the saline solution is therefore probably, on the whole, best adapted to the purpose. When ammonium nitrate is heated to the point of decomposition, it is wholly resolved into aqueous vapor and nitrogen monoxide, according to the reaction:

But it is necessary not to let the heat employed in the process be too high, as otherwise, besides nitrous oxide, there will come over portions of nitric oxide, uncombined ammonia, and probably even nitric acid, which contaminate the product, and render it unfit for use. This may be avoided by arresting the process as soon as any white fumes appear in the retort. Peculiar care also must be taken that the ammonium nitrate should be pure, and especially free from ammonium chloride, which might cause an admixture of chlorine in the product. To insure against impurities of this kind, it is best in any case in the least doubtful, and perhaps it might be best in all cases, to cause the nitrous oxide, before it is used by inhalation, to pass successively through two solutions: one, of ferrous sulphate, to remove any nitric oxide that might be present; the second, of potassium or sodium hydroxide, to neutralize acid impurities and chlorine. At times nitrogen gas is also found in the nitrogen monoxide, probably resulting from a trace of nitrite present or some reducing action upon the nitrate in the moment of its decomposition. When the monoxide is liquefied under pressure this free nitrogen remains as unliquefied gas.

Nitrogen monoxide gas is colorless, nearly or quite odorless, slightly sweetish to the taste, and of the sp. gr. 1.527. Cold water will absorb about three-fourths of its bulk of the gas, and, under pressure, much more, and, thus impregnated, has a slight, not unpleasant odor, and a sweetish taste. By the joint influence of cold and pressure the gas may be condensed into a liquid, which is colorless, very mobile, and capable, under the ordinary atmospheric pressure, of remaining liquid at $-12.7^\circ C.$ ($9^\circ F.$). The liquefaction was effected by Bianchi at $0^\circ C.$ ($32^\circ F.$), under a pressure of thirty atmospheres. (*A. J. P.*, 1865, 275.) Inflammable bodies will generally burn with increased vigor in nitrous oxide, which is entirely incapable of giving oxygen to the blood.

The anæsthetic property of nitrogen monoxide was discovered by Humphry Davy; but the first practical application of it to this purpose was made by Horace Wells of Connecticut.

For short minor surgical operations the gas is an excellent anæsthetic, but in severe operations it is not to be relied on, any interruption of the inhalation being followed by immediate return to consciousness. The apparatus required for its production, storage, exhibition, and administration is also so cumbrous that practically nitrous oxide is only employed by the dentist. It is certainly a very safe agent when used with due care, although it has caused death. The common

mode of exhibition is by means of an air-tight bladder or bag, with a tube and mouth piece attached.

Nitrous Oxide Water.—Water impregnated under pressure with nitrogen monoxide forms the *nitrous oxide water*, or so-called *oxygenous aerated water*, which has been used to some extent as an internal remedy, but is probably physiologically inactive and has passed into desuetude.

Nitro-Propiol. *Ortho-nitro-phenyl-propiolio acid*, when heated with grape sugar in the presence of soda, forms indigo, according to the following equation:

The formation of indigo is rendered evident by a blue coloration of the fluid. The compound therefore serves as a qualitative test for the glucose in urine. Von Gerhardt recommends the following method for carrying out the test: Place 10 to 15 drops of the urine under examination in a test tube, add one hundred and sixty minims (10 Cc.) distilled water and a nitro-propiol tablet, and carefully heat the mixture for two to four minutes. In the presence of sugar the fluid first becomes green and subsequently intensely blue. This reaction is sufficiently sensitive to indicate with certainty 0.3 per cent. of sugar and possesses the advantage that it only takes place if grape sugar is actually present in the urine.

Njimo Wood.—*Njimo* was introduced into Germany from the Cameroons with the statement that it had digestive properties similar to those of pepsin. It is a stem wood, often with pieces of root, of a yellow color, musk-like odor, and bitter taste. Schulz (*Ph. Ztg.*, June 12, 1886) finds that it is not a digestive, and that it yields a resinous extract not poisonous to frogs. The alcoholic extract of the drug is yellow by transmitted light, but exhibits a green fluorescence resembling uranium glass.

Noctilucine.—For an account of this substance, to which is ascribed the phosphorescence of animals, see *J. P. C.*, 4e sér., xvii.

Normalin is said to contain hæmoglobin and arsenic serum-albuminate, and to be an alterative tonic used in skin diseases and various other disorders in which such an alternative is indicated.

Nosophen. *Tetra-iodo-phenol-phthalein.*

Nosophen is obtained by the action of iodine on solutions of phenolphthalein. It is an impalpable, yellowish-gray, odorless, tasteless powder, containing 61.7 per cent. of iodine in combination. It may be heated up to 220° C. (428° F.) without decomposition. It is insoluble in water and acids, soluble with difficulty in alcohol, glacial acetic acid, ether, and chloroform, but readily soluble in alkalis, with the last of which it forms salts from which it is easily freed at low temperature by carbon dioxide. In the presence of heat it liberates carbon dioxide from its alkaline salts. By virtue of its two hydroxyl groups, nosophen is an acid, readily soluble in alkalis with replacement of the hydrogen atoms of both hydroxyl groups by a metal. Two of the salts of nosophen have been put upon the market,—the sodium salt (antinosine) and the bismuth salt (eudoxine).

Antinosine has the following structural formula:

It is a dark blue, amorphous powder which is readily soluble in water and alcohol.

Eudoxine has the formula:

It is a reddish-yellow, tasteless, odorless powder, insoluble in water, which is decomposed by alkalis into bismuth oxide and a soluble salt of tetra-iodo-phenol-phthalein. It contains 52.9 per cent. of iodine and 14.5 per cent. of bismuth.

Medicinal Properties and Uses.—It is stated that in nosophen and its two salts the iodine is so firmly combined that it is not liberated in the human system, either when applied locally or administered internally, and that the preparations are therefore incapable of producing toxic effects. It is further affirmed that nosophen is in itself germicidal and locally an alternative, and that, being free from toxic properties, it is superior to iodoform. It is not irritant, and may be used freely as a local application in powdered form in all those cases to which iodoform is applicable, and has been especially recommended in nasal and laryngeal diseases. It has been administered internally as an intestinal antiseptic in doses of from five to eight grains (0.32–0.5 Gm.).

It is affirmed that antinosine has the same general properties as a germicide as nosophen, and that being soluble in water it affords a valuable application in many cases to which the nosophen as a dusting powder is scarcely applicable. The strength of the local application varies: from 2 to 3 per cent. in diseases of the nose, mouth, and throat, from 1 to 2 per cent. in *gonorrhœa*, from $\frac{1}{2}$ to 1 per cent. for irrigation of the bladder and in *cystitis*, from 1 to 500 to 1 to 1000 for washing out of the stomach in *gastro catarrh*, *cancer*, etc.

Its 2 per cent. solution is said by W. F. Coleman to act most favorably in all forms of external inflammation about the eye, in purulent *otitis media*, etc. Owing to its solubility in water and its freedom from odor and taste, it is coming into vogue as a mouth wash; for this purpose its glycerin solution is preferable, aromatics being added to taste. A teaspoonful (3.75 Cc.) of the 1 per cent. solution in a tumblerful of water is the strength commonly employed, but when there is a severe *stomatitis* a 2 per cent. or even stronger solution may be used without dilution.

Its intravenous use has been suggested, but, according to Binz and Zantz (*Fort. Med.*, xiii. 1895), it is decomposed in the blood when so given and nosophen precipitated.

Eudoxine is believed to be slowly decomposed by the alkaline juices of the intestines, with liberation of antinosine and bismuth. It has been given in doses of from a half to eight grains (0.032–0.5 Gm.) three times a day, with alleged most excellent results, in *diarrhœas*, *gastro* and *intestinal indigestions*, and even *gastro cancer*.

Nuclein is a compound proteid closely resembling mucin, but distinguished by its phosphorus content (1.89–2.88 per cent.), while it contains no sulphur. It is probable that numerous varie-

ties of nuclein exist, all being compounds of simple proteids with *nucleic acid*. Nuclein may be isolated by treating the cells with artificial gastric juice, by which the investing protoplasm is dissolved, leaving the nuclein unaffected. Nucleic acid is an amorphous white powder of strong acid reaction, readily soluble in water containing a small amount of alkali, insoluble in alcohol and ether.

The nuclein solution is a 5 per cent. solution of nucleic acid from yeast in water. It is at present probable that nucleic acid, when given internally, enters the circulation and circulates unchanged. It has been asserted that it has an extraordinary power in improving the general nutrition and increasing the resistive power of the system to pathogenetic germs, and is therefore a very valuable remedy in *tuberculosis*, in *anæmia*, in *general debility*, in *neurasthenia*, and even in acute germ diseases, such as *diphtheria*. It appears to be non-toxic, since Vaughan and McClintock have injected it into the blood of animals in such amount that the entire blood contained 1.8 per cent of pure nucleic acid, and it is probable that the good results which have occasionally followed its use in practical medicine have been accidental, or due to a psychical influence rather than any remedial power of the remedy. The assertion frequently made that nucleic acid is the substance to which the human body owes its resistive power to morbid organisms is unproved and highly improbable. Its hypodermic injection produces so much pain that patients will rarely tolerate it. According to its manufacturers, the 5 per cent. solution may be given in *doses* of one fluidrachm (3.75 Cc.) three times a day.

Various metallic compounds of nucleic acid have been put upon the market, as follows:

Cuprol. Copper Nucleinate.—Cuprol occurs as a greenish powder, soluble in water, containing about 6 per cent. of metal. It is used as an astringent alternative application in all those cases in which the older copper salts have been employed. In *conjunctivitis* a 5 to 10 per cent. solution has been recommended, and it is claimed for it that it produces little gastric inflammation.

Ferrinol. Ferric Nucleinate.—Ferrinol is a brown powder, freely soluble in water, containing about 6 per cent. of iron and 4.5 per cent. of phosphorus combined in the nuclein. It is stated that it produces little gastro-intestinal irritation.

Mercuriol. Mercuric Nucleinate.—This is a colorless or brownish-white powder containing 10 per cent. of mercury, soluble in water with a weak alkaline reaction, and has been used both internally and locally as a substitute for corrosive sublimate, over which it has the advantage of not coagulating albumin. In *syphilis* from half to one grain (0.032–0.065 Gm.) of it may be given hypodermically. Two grains (0.13 Gm.) are said to have produced salivation.

Nargol. Argentic Nucleinate.—This substance forms a light brownish-white powder, readily soluble in water, contains 10 per cent. of silver, and has been recommended as a local application in all forms of diseases for which silver nitrate has been used. It is stated that it is much less irritating even than protargol, and that on account of its not coagulating albumin it has great penetrating power. It may be used in solution up to 25 per cent. on most mucous membranes. The solution should be recently made, as it undergoes change after a few weeks.

Nutrin.—This is a fatty saccharated albuminated compound derived from olive oil, of which it is said to contain 51 per cent. The preparation formerly called *nutrin*, a meat-albumin product, has been withdrawn from commerce. *Nutrin* is reported to be a palatable, digestible cholagogue and a substitute for cod liver oil.

Nymphæa.—The seed of *Nymphæa lutea*, L. (*Nuphar luteum*, Sibth. and Sm.), *Yellow Pond Lily* (Fam. Nymphæaceæ), according to W. Gruning, contains *nuphar-tannic acid*, $C_{56}H_{56}O_{38}$, in considerable quantity. (A. J. P., 1883, 96.) The name *Nymphæa* has been incorrectly applied also to the white pond lilies, which belong to the genus *Castalia*, *Castalia odorata* (Dryand.), Woodv. and Wood. (*Nymphæa odorata*, Dryand.), *Sweet-scented Water Lily*. The root of this well-known American plant is very astringent and bitter, and, according to Bigelow, contains much tannin and gallic acid. The root of *Castalia alba* (L.), Lyons (*Nymphæa alba*, L.), or European *white water lily*, was esteemed anaphrodisiac by the ancients. The tannic acid contained in this root has been named *nymphæa-tannic acid*, and the formula $C_{56}H_{56}O_{38}$ given it. (A. J. P., 1883, 96.)

Nyssa. *Nyssa aquatica*, L. (*N. uniflora*, Wang.) *Tupelo Gum*. *Sour Gum*. *Swamp Tupelo*. (Fam. Cornaceæ.)—*Tupelo root* has been recommended for surgical tents. (A. J. P., 1883.)

Oatmeal. Avenæ Farina. Farine d'Avoine, Fr. Hafermehl, G. Farina dell'Avena, It. Harina de Avena, Sp.—Avena sativa, L., or the common oat, is so well known that a minute description would be superfluous. It is specifically distinguished by its "loose panicle, its two-seeded plumes, and its smooth seeds, one of which is awned." It was known to the ancients, and is now cultivated in all civilized countries; but its original locality has not been satisfactorily ascertained. It grows wild in Sicily, and is said to have been seen by Anson in the island of Juan Fernandez, off the coast of Chili. The seeds deprived of their husks are sometimes known as *groats*. As a human food coarsely ground oatmeal is usually preferred to the fine meal, and the grain grown in a northern climate is superior to that produced farther south. Hence Canada and Irish and Scotch oatmeals are better than the meals produced in the middle of the United States, the product of which country is chiefly consumed by horses. Diuretic properties have been attributed to the oatmeal, but probably incorrectly. *Tinctura Avenæ Sativæ* may be made by percolating 4 troyounces of the ground oatmeal with 1 pint of diluted alcohol, reserving the first 5½ fluid-ounces, and evaporating the remainder down to half a fluidounce and adding to the reserved portion. (H. E. Heinitch, A. J. P., 1886, 86.)

Oatmeal contains, according to Vogel, in 100 parts, 59 of starch, 4.30 of a grayish substance, resembling coagulated albumin rather than gluten, 8.25 of sugar and a bitter principle, 2.50 of gum, 2 of fixed oil, and 23.95 of fibrous matter, including loss. A very elaborate report on the composition of American cereals by Clifford Richardson (*Department of Agriculture, Bulletin No. 9, 1886*) gives as the average ratio in oats from all parts of the country 70 per cent. of kernel to 30 per cent. of husk. According to the same authority, the composition of the kernel (average of 179 analyses) is as follows: water, 6.93 per cent.; ash, 2.15; oil, 8.14; carbohydrates, 67.09; fibre, 1.38; albuminoids, 14.31; corresponding to

nitrogen per cent. 2.28. The nitrogenous principle has been called *avenin*, and resembles legumin somewhat. Ritthausen (*Die Eiweisskörper*, Bonn, 1872, 135) considers Nordin's *avenin* to have been a mixture of legumin or vegetable casein and a vegetable gluten containing sulphur, to which he gives the name *gliadin*, the legumin, however, predominating.

Gruel made with fine oatmeal affords a nutritious, bland aliment, which, from its somewhat laxative tendency, is often preferable to other amylaceous preparations. Oatmeal gruel may be prepared by boiling an ounce of the meal with three pints of water, to a quart, straining the decoction, allowing it to stand until it cools, and then pouring off the clear liquor from the sediment. Sugar, lemon juice, or wine may be added to improve its flavor.

Ochres.—These are native mixtures of argillaceous or calcareous earth and iron and manganese oxides, employed in painting. They are prepared for use by agitating them with water, decanting the turbid liquor after the coarser particles have subsided, then allowing it to rest in order that the finer parts may be deposited, and, lastly, drying the sediment which forms. The color of the ochres varies with the state of oxidation of the iron, and with the proportion which the iron bears to the other ingredients, and is sometimes artificially modified by the agency of heat. Several varieties are known in commerce under different names, according to their color or place of origin. Such are the *brown ochre*, the *yellow ochre*, the *red ochre*, the *Roman ochre*, of a brownish-yellow changing by heat to a purple-red, the *Oxford ochre*, of a brownish-yellow color less deep than the Roman, and the *French ochre*, which is yellow. The *Indian red*, from the Persian Gulf, and the *Spanish brown* and *Venetian red* may also be ranked in this class of pigments. Sometimes ochres come in powder, and sometimes in hard masses known as *stone ochres*.

Ocimum. *Ocimum Basilicum*, L. *Basil*. *Sweet Basil*. *Grand Basilic*, Fr. *Basilienkraut*, G. (Fam. Labiate.)—An annual aromatic plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. It yields by distillation a yellowish-green volatile oil, lighter than water, which on being kept solidifies into a crystalline camphor, isomeric with turpentine camphor. (Gmelin's *Handbook*, xiv. 359.) Basil has the ordinary properties of the aromatic plants, and is used as a condiment. The seeds are said by Ainslie to be used in India in *gonorrhœa*.

Odontodol.—This is said to be a mixture of one part each of cocaine hydrochloride and oil of cherry laurel, 10 parts of tincture of arnica, and 20 parts of solution of ammonium acetate.

Enanthe. *Æ. crocata*, L. *Water Hemlock*. *Water Dropwort*. *Dead Tongue*.—A perennial umbelliferous, aquatic European plant, exceedingly poisonous both to man and inferior animals. The root, which has a sweetish not unpleasant taste, is sometimes eaten by mistake for other roots, often with fatal results. The symptoms produced are those of irritation of the stomach, besides failure of circulation, and great cerebral disturbance, indicated by giddiness, convulsions, and coma. (See *P. J.*, 1874, 202.) Externally applied, the root produces redness and irritation of the skin, with an eruption. It is said to be sometimes used empirically as a local remedy in *piles*. Other species of *Enanthe* are poisonous, and the whole genus should be suspected. We

have two or three indigenous species. In cases of poisoning, the stomach should be at once evacuated, and symptoms met as they arise. A peculiar resinoid principle, denominated *enanthin*, has been found by Gerding in *Enanthe fistulosa*, L., the common water hemlock of Europe, of which half a grain (0.032 Gm.), given to an adult, produced long-continued irritation of the fauces, and a grain (0.065 Gm.), occasional vomiting. (See *A. J. P.*, xxi. 68.) A resinous principle, *enanthotoxin*, $C_{17}H_{22}O_6$, has been extracted from *Æ. crocata*, which is reputed to be very poisonous. In the *P. J.*, vol. xvi. 357, is a paper by Henry William Jones upon the recognition of *Æ. crocata* in cases of suspected cattle poisoning; he found that the starch granules possessed characters which enabled him to distinguish the tubers from all others.

Enanthe Phellandrium, Lam. *Phellandrium aquaticum*, L. *Fine-leaved Water Hemlock*. *Fructus Phellandrii*. *Wasserfenchel*, G. *Phellandrie aquatique*, Fenouil d'Eau, Fr.—A biennial or perennial, umbelliferous, European water plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The seeds are from a line to a line and a half in length, ovate-oblong, narrow above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx, and with the erect or reverted styles. Their color is yellowish brown; their odor peculiar, strong, and disagreeable; their taste acrid and aromatic. Among their constituents is a volatile oil, upon which their aromatic flavor depends. By C. Fronefeld it has been rendered probable that they contain a volatile alkaloid, analogous to coniine, if it be not coniine itself, for if the powdered seeds are rubbed with solution of potassa, the peculiar mouse-like odor of that alkaloid is exhaled. The powder was submitted to distillation with caustic potassa, the alkaline liquid obtained was neutralized with sulphuric acid and evaporated to a syrupy consistence, alcohol was added to precipitate the ammonium sulphate, the liquid was then filtered, treated with caustic potassa, and again distilled. On the surface of the distillate a yellow oily fluid floated, which was only slightly soluble in water but readily so in ether and alcohol, evinced an alkaline reaction with turmeric paper, and neutralized the acids. (*A. J. P.*, May, 1860, 211.) In overdoses the seeds produce vertigo, intoxication, and other narcotic effects. They have been used in chronic pectoral affections, such as *bronchitis*, *pulmonary consumption*, and *asthma*; also in *dyspepsia*, *intermittent fever*, *obstinate ulcers*, etc. The dose of the seeds, to commence with, is five or six grains (0.32–0.4 Gm.), so repeated as to amount to a drachm (3.9 Gm.) in twenty-four hours. They should be given in powder. Dose of the alcoholic extract, three grains (0.2 Gm.). (*P. J.*, xii. 591.)

Enothera. *Enothera biennis*, L. *Tree Primrose*. *Evening Primrose*. *Onagre*, Fr. *Nachtkerze*, G. (Fam. Onagraceæ.)—The fleshy root of this plant, before the introduction of the potato, was used as a table vegetable. Many years ago R. E. Griffith commended very highly a strong decoction of the plant frequently applied in eruptive skin diseases. More recently the drug has been commended in *whooping cough* and spasmodic *asthma*, and the ointment has been used in *prurigo* and other cutaneous affections of in-

fants, and as an application to ulcers. Dose of fluidextract, from a half to one fluidrachm (1.8–3.75 Co.). The ointment may be made by incorporating four ounces of the fluidextract in a pound of vaseline or lard.

Esypos.—A cheap, crude wool fat obtained as a by-product in cleansing sheep wool. (See *Adeps Lanae Hydrosus*, p. 96.)

Oil of Ajowan. *Oleum Ajowan*, Br. Add. *Ptychotis Oil*.—The oil distilled from the fruit of *Ptychotis Coptica* (L.), Lyons (*Ammi Copticum*, L., *Carum Copticum*, Benth., *O. Ajowan*, Bentley). Under the name of *ajowan*, *ajcain*, *ajwan*, and other vernacular appellations, the seeds of *Ptychotis Coptica* are largely used in India as an aromatic. They resemble in size the fruits of the ordinary parsley and are of a grayish-brown color and have a tubercular surface with five prominent ridges to each mericarp. The odor and taste resemble that of thyme. These fruits yield from 4 to 6 per cent. of an agreeably aromatic volatile oil. Ajowan oil is officially described as "colorless, with an odor and taste resembling thyme. Specific gravity 0.917 to 0.930. It rotates the plane of a ray of polarized light from 1.0° to 1.5° to the right in a tube 100 Mm. long. If a portion of the oil be cooled to 0° C. (32° F.), it should yield from 30 to 36 per cent. of crystalline thymol." Br. Add. Oil of ajowan is used for the same purposes as allied aromatic oils in doses of from one-half to three minims (0.032–0.2 Co.).

Oil of Akee.—This is a yellow, non-drying, butter-like fat obtained from the *Blighia sapida* of Koenig (Fam. Sapindaceæ), native of Guinea, but cultivated in Jamaica. (P. J., 65, p. 691.)

Oil of Aleurites triloba.—The *Aleurites triloba*, Forst., is a small tree belonging to the Euphorbiaceæ. It is widely diffused throughout the tropics. The fruit is a nut nearly as large as a walnut, consisting of a thick shell enclosing a kernel containing much azotized matter and rich in oil, of which it is said to yield nearly one-half its weight by expression. The nuts strung together on the fibres of the palm leaf were formerly used in many Pacific islands as a substitute for candles. The oil has been long known in the various countries inhabited by the plant, being called in Jamaica *Spanish walnut oil*, in India *Belgaum walnut oil*, in Ceylon *kekune oil*, and in the Hawaiian Islands *kukui oil*. It is very fluid, of an amber color, without odor, of a nutty, pleasant taste, congealing at 0° C. (32° F.), insoluble in alcohol, readily saponifiable, "and very strongly drying." It is said to be a mild cathartic, acting like castor oil, but more promptly and without griping effects. (J. P. O., 3e sér., xxiv. 228.) The dose is from one-half to one fluidounce (15–30 Co.), the smaller quantity generally answering. The cake left after the expression of the oil, given to a dog in the dose of about half an ounce (15 Gm.), produced no vomiting, but acted strongly as a purgative.

The oil of the *Tung Tree*, *Aleurites cordata*, R. Br. (the synonyms being *Elæococca cordata*, *Elæococca vernicia*, *Dryandra cordata*, and *Dryandra vernicia*), is used to a large extent in the arts in China, under the name of *wood oil*. It is prepared in China by a crude process of expression. It occurs in two forms, *white oil*, a moderately thick, yellowish, transparent liquid, and the *black oil*, which is thick, blackish, and opaque. Wood oil is used in China and Japan either as a direct application to wood or mixed with various sub-

stances, as lacquer varnish, or paint. Its most remarkable property is its extraordinary siccativ quality, which is said to exceed that of any known oil. When applied to wood it forms a resinous layer which is affirmed to be impermeable by water and ordinary solvents. Wood oil is also exported to Europe, where it is used in the making of varnishes. According to R. H. Davies, its sp. gr. at 15.5° C. (60° F.) is 0.94015; it remains liquid at –13.3° C. (8° F.). 100 Gm. of the oil require 0.39 Gm. potassium hydroxide for neutralization, and 21.1 Gm. for complete saponification. (P. J., 1885, 636.) E. M. Holmes believes that the dark colored oil is made by boiling the kernels previous to expression, the cold drawn oil being colorless, inodorous, and nearly tasteless. The latter, according to Clôëz (*C. R. A. S.*, 1875, vol. lxxxi. 469), has the sp. gr. 0.9362, congeals at –18° C. (–0.4° F.) to a transparent mass, solidifies rapidly when exposed to light in a closed vessel, and is the most drying oil known. (C. D., May, 1902.) It has been used in *ulcerations and skin diseases*.

Oil of Anda.—A fixed oil procured by expression from the seeds of *Joannesia princeps*, Vell. (*Anda brasiliensis*, Raddi, A. Gomesii, A. Juss., *Andicus pentaphyllus*, Vell. (Fam. Euphorbiaceæ). The bark of *J. princeps*, of Brazil, yields on being wounded a milky juice, which is said to be poisonous, and to be used for stupefying fish. The fruit, which is about as large as an apple, ash-colored, with two larger and two smaller angles, encloses a two-celled nut, containing two seeds, about the size of a chestnut. Like the seeds of other euphorbiaceous plants, these are actively purgative, one seed, according to Martius, being the dose for a man. By expression these seeds yield a pale yellow, transparent oil, with little odor or taste, which is said to be used in Brazil for burning and painting. It has a sp. gr. 0.927, and in properties belongs to the class of semi-drying oils. Mello Olliveira has found in it an alkaloid, *joannesine*, which Couty affirms to be inert. (N. R., 1881, 260.) Norris, who tried the oil at the Pennsylvania Hospital, found it to operate on the bowels moderately in the dose of fifty drops (2.5 Co.), and copiously when more largely given. Manoel de Castro and other Brazilian physicians assert that in doses of from one to two teaspoonfuls (3.75–7.5 Co.) it acts in a manner very similar to castor oil, over which it has the great advantage of not being nauseous to the taste.

Oil of Anise Bark.—There has appeared in the European markets a bark, closely resembling Massoi bark, derived from an unknown source in Madagascar, which yields fully three and a half per cent. of a light yellow oil, the odor of which slightly resembles safrol. It has a spicy taste, but is only slightly sweet. Its specific gravity is 0.969 at 15° C. (59° F.). Optical rotation –0° 46' in a 100-Mm. tube. Refraction equivalent for the sodium line at 16° 1.52510. It contains a small quantity of ordinary anethol, but consists principally of the isomeric fluid anethol, the *methyl-chavicol* of Eykman, $\text{CH}_3\text{O.C}_6\text{H}_4.\text{CH}_2.\text{CH}:\text{CH}_2$.

Oil of Ben.—This is a fixed oil extracted from the seeds of *Moringa pterygosperma*, Gaertn. (*Hyperanthera Moringa*, Vahl.), and *M. aptera* of Gaertner, and not to be confounded with oil of benne from *Sesamum indicum*, L. (Fam. Pedaliaceæ). These are trees of the fam. Moringaceæ, inhabiting different parts of India,

Arabia, Syria, etc., and introduced into the West Indies. James Macfadyen, in his *Flora of Jamaica* (i. 325), states that it is not the *M. pterygosperma* which yields the commercial oil of ben, but the *M. aptera*, which has not been introduced into Jamaica. He says, however, that an excellent and palatable oil may be obtained by expression from the seeds of *M. pterygosperma*, growing in that island. The leaves and other parts have an acrid property, which has probably given the name of *horseradish tree* to *M. pterygosperma*. According to Henry Shachan (*Nouv. Rem.*, 1890), the tincture of the root is very actively diuretic and useful in cardiac dropsy. The oil of the seeds has long been known, though used in the arts rather than in medicine. It is prepared in Europe from the seeds brought from Egypt; and it would appear, from the statements of Macfadyen, that the idea generally prevailing that it is also extracted in the West Indies is incorrect. The oil has a sp. gr. of from 0.912 to 0.917; it solidifies at about 0° C. (32° F.); indeed at 7° C. (44.6° F.) it begins to deposit the solid fats. It is inodorous, clear, and nearly colorless, and keeps long without becoming rancid. It resembles olive oil, and is used for similar purposes. Mérat and De Lens say that it is purgative; but most of the fixed oils are so in sufficient doses. According to Völcker, the oil contains palmitin, olein, and a peculiar fatty matter yielding an acid by saponification, which he names *benic* (or *behenic*) acid. (*J. P. C.*, xvi. 77.) Heintz considered benic acid as simply a mixture of palmitic and myristic acids. (*Pogg. Ann.*, xcii. 601.) It is, however, now recognized as one of the normal fatty acid series, possessing the formula $C_{22}H_{44}O_2$.

Oil of Bergamot. *Oleum Bergamotte*. U. S. 1890. *Oleum Bergamii*, U. S. 1880.—“A volatile oil obtained by expression from the rind of the fresh fruit of *Citrus Bergamia* Risso et Poiteau (nat. ord. *Rutaceae*). It should be kept in well-stoppered bottles, in a cool place, protected from light.” U. S. 1890.

Citrus Bergamia.—The bergamot tree has oblong-ovate, dentate, acute, or obtuse leaves, somewhat paler on the under than on the upper surface, and with footstalks more or less winged or margined. The flowers are white, and usually small; the fruit is pyriform or roundish, about three inches in diameter, terminated by an obtuse point, with concave receptacles of oil in the rind. The pulp of the fruit is sourish, somewhat aromatic, and not disagreeable. The rind is shining, and of a pale-yellow color, and abounds in a very grateful volatile oil. This may be obtained by expression or distillation. In the former case it preserves the agreeable flavor of the rind, but is somewhat turbid; in the latter it is limpid but less sweet. The mode of procuring it by expression is exactly the same as that used for oil of lemon. (See *Oleum Limonis*.) It is brought from Italy, the south of France, and Portugal.

The oil of bergamot, often called *essence of bergamot*, has a sweet, very agreeable odor, a bitter, aromatic, pungent taste, a pale greenish-yellow color, and a slightly acid reaction. Its sp. gr. varies from 0.870 to 0.888. (Lewis, Zeller.) “Specific gravity: 0.880 to 0.885 at 15° C. (59° F.). Its optical rotation should not be more than 20° to the right in a 100 Mm. tube, and at a temperature of about 15° to 20° C. (59° to 68° F.). Two volumes of the Oil, when mixed

with 1 volume of alcohol, should give a clear solution of a slightly acid reaction, and this solution should not become turbid on the further addition of alcohol (distinction from oil of orange or oil of lemon). The oil should also be soluble at 20° C. (68° F.), without the separation of oily drops, in 1.5 to 2 volumes of alcohol of 80 per cent. by volume. It is soluble, in all proportions, in glacial acetic acid. If about 2 Gm. of the Oil be evaporated in a small, tared capsule, on a water-bath, until the odor has completely disappeared, a soft, green, homogeneous residue should be left, amounting to not more than about 6 per cent. of the Oil (absence of fatty oils).” U. S. 1880. It contains limonene, dipentene, linalool, a solid greasy compound called *bergaptene*, or *bergamot camphor*, and *linalool acetate*, $C_{10}H_{17}.C_2H_5O_2$, which latter makes up about 40 per cent. of the expressed oil, but is decomposed in large part by the process of steam distillation. Bergaptene has been very fully studied by Pomeranz. (*M. Chem.*, 1891, 379.) It melts at 188° C. (370.4° F.), and has the composition $C_{12}H_{20}O_4$, being the lactone or inner anhydride of *bergaptenic acid*, $C_{12}H_{20}O_5$. By fusion with potassium hydroxide, bergaptene yields *phloroglucin*. (See *Schim. Rep.*, April, 1893, and 1895, 24; also *Proc. A. Ph. A.*, 1897, 630.) The oil is distinguished from lemon and orange oils by readily dissolving in solution of potassium hydroxide and forming with it a clear solution. (Zeller.) Though possessed of the excitant properties of the volatile oils in general, it is employed chiefly, if not exclusively, as a perfume.

Oil of Chione.—The bark of this West Indian tree, *Chione glabra*, yields on distillation 1.5 per cent. of a light yellow volatile oil, consisting chiefly of *o-cayaacetophenone*, $C_8H_8.OH.CO.CH_3$. A compound obtained synthetically from *o-nitrocinnamic acid* proved to be identical with that isolated from the oil. (See *J. Chem. S.*, vol. lxxv. 1899.)

Oil of Citronella. *Oleum Andropogon Nardi*. This oil is distilled from the *Andropogon Nardus*, L. (Fam. Gramineae), a plant growing sometimes to the height of five or six feet, which is cultivated in Ceylon and in the Straits Settlements, and also on the Malabar coast. According to the statements of Consul Freudenberg, this oil is produced largely in the southern provinces of Ceylon by natives, either by distillation with steam or with a naked fire. The production and exportation of Ceylon citronella oil reached a maximum in 1899 when the exportation was 1,478,756 pounds, whereas in 1903 it amounted to 1,062,594 pounds, of which 554,689 pounds came to the United States. Some came from other sources, however, as the total importations of citronella oil into the United States for 1903 were 725,842 pounds, and in 1904, 828,446 pounds. For a method of production, see *West. Drug.*, 1888, 243. Oil of citronella is of a yellowish-green color, having a characteristic odor and pungent taste. Its sp. gr. is, according to Gildemeister and Hoffman, 0.886–0.900. It mixes with alcohol in all proportions, and the test for purity given by Schimmel & Co. is based upon its behavior towards alcohol of 80 per cent.: “One volume of the oil must form an absolutely clear solution with *two* or at most *two and a half*, volumes of 80 per cent. alcohol at a temperature not below 20° C. (68° F.). A cloudy mixture indicates the presence of turpentine, certain fixed oils, and other essential oils which are sometimes used

to adulterate it." The oil contains, according to Gildemeister and Hoffman (*Ätherische Öle*, p. 377), *camphene*, *diptene*, *methyl heptenone*, *citronellal*, *borneol*, and *geraniol*, and esters of acetic and valeric acids. Oil of citronella is an aromatic not used in medicine, but largely employed in perfuming so-called *honey soap*. Externally applied it protects against the attacks of mosquitos and other insects.

Oil of Coconut. *Cocconut Oil.* *Cocconut Butter.* *Oleum Cocos*, P. G. *Oleum Cocos*. *Beurre de Coco*, Fr. *Kokosnussöl*, G.—This must not be confounded with the fixed oil of the chocolate nut, which is often called *cocoa butter*. (See *Oleum Theobromatis*, p. 881.) The substance here considered is the fixed oil of the coconut, which is the fruit of a species of palm, *Cocos nucifera*, L., universally known as the *coconut tree*, or *cocconut tree*. The oil is obtained either by expression or decoction, often by *insolation*,—i.e., exposing the rasped nuts to the heat of the tropical sun. It is of a fine white color, of the consistence of lard at ordinary temperatures, becoming solid, like suet, between 4.4° C. (40° F.) and 10° C. (50° F.), and liquid at about 26.7° C. (80° F.), of a bland taste, and a peculiar, not disagreeable odor. It is readily dissolved by alcohol. It contains large quantities of the glycerides of myristic and lauric acids, with smaller quantities of the glycerides of palmitic and oleic acids. It has also been found to contain several volatile acids, as caproic, caprylic, and capric acids. (Lewkowitsch, *Chemical Analyses of Oils, Fats, and Waxes*, 2d ed., 1898, 538.)

The oil has been used for various purposes in medicine and pharmacy. It has been employed as a substitute for cod liver oil, especially in the form of a proprietary preparation, *coco-olein*. In Germany it has been used in pharmacy, to a considerable extent, as a substitute for lard, to which, according to Pettenkofer, it is preferable on account of its lesser tendency to rancidity, its more ready absorption when rubbed on the surface of the body, and its lesser liability to produce chemical changes in the substances with which it is associated. Thus, the ointment of potassium iodide, when it is made with lard, becomes yellow in a few days, while, if made with coconut oil, it remains unchanged for two months or more. Vegetable substances also keep better in ointments prepared with this oil than with lard. Besides, it takes up one-third more water, which is a useful quality when it is desirable to apply saline solutions externally. To prepare it for use, nothing more is ordinarily necessary than to melt it at a moderate heat, and strain it through linen. If colored, it may be digested with powdered animal charcoal, and subsequently filtered through paper. (A. J. P., xxix, 331.) When chilled and pressed, a solid residue, which is *coco-stearin*, is obtained. This is extensively used as a substitute and adulterant of the genuine *cocoa butter* in the confectionery trade. Coconut oil is employed in the manufacture of soap, particularly of the transparent varieties, and the so-called "*marine soaps*" and *filled soaps*; it is also largely used for giving firmness to the ordinary soap; this property also permits of the addition of a large quantity of water to the soap. Unfortunately, coconut oil soap is very apt to contain free caprylic acid; and the persistent rancid odor, resembling that of infants' vomit, left upon the skin after washing with its soap is an effectual bar to its very extended use. The exportations of coconut

oil from Ceylon amount to 15,000 tons annually, from British India to 4000 to 6000 tons, and from the Dutch Indies to 1300 tons per annum. Besides the oil itself, the dried pulp of the coconut is sent to European markets in large amounts under the name of *copra*. The export of copra from Ceylon amounts to 5000 tons annually, from Tahiti to 4000 tons, from Samoa to 3000 tons, and from Singapore to 4000 tons.

The importations of coconut oil into the United States for 1905 amounted to 43,773,208 pounds, valued at \$2,568,048.

According to Parisi, the endocarp or meat of the coconut is a powerful tennicide. The patient should drink the milk and then eat the flesh of the nut. The coconut is said to be largely used in India as a vermifuge, and the matter appears to have practical importance.

Powdered coconut shells have been largely used in America as an adulterant for spices. Their debris is readily recognized by the microscope. (See A. J. P., 1901.)

Oil of Colza.—An oil expressed from the seed of *Brassica campestris*, L., or *field cabbage*, a cruciferous plant which grows wild through the greater part of Europe, and is largely cultivated in France and Germany for the sake of this oil. Colza oil is used in Europe as a burning oil, as a lubricating oil, and, after purification by heating with starch, as a table oil. The raw oil has a sp. gr. of 0.915, and the refined oil 0.9136. Chilled to -4° C. (24.8° F.), stearin separates out, and at -6° C. (21.2° F.), it becomes a yellowish buttery mass. The oil contains the glycerides of stearic, *erucic* (or *brassic*) acid, $C_{22}H_{42}O_2$, and an acid, isomeric with but differing in some respects from ordinary oleic acid. The total consumption of rape and colza oil in Europe is estimated at from 280,000 to 300,000 tons per annum. For analysis of commercial samples, see C. D., 1894, 140.

Oil of Cypress.—An oil derived from *Cupressus sempervirens*, L. (Fam. Conifera), has been strongly recommended by Bravo in *whooping cough*; it is used by sprinkling the oil upon the clothes, bed, etc., of the patient.

Oil of Dægling. *Oleum Chanoceti.* *Dægling Oil.* *Dægling Thran.* *Huile de Rorqual Rostre*, Fr. The oil derived from the Norwegian whale, *Balaena rostrata*, is said by Gustave Guldberg to possess a lower specific gravity than any other animal oil (0.876 at 15° C.), and also remarkable penetrative properties. It is affirmed that if mixed in equal quantities with chloroform it carries the latter agent through the skin, and enables it to act as a local anesthetic in *pruritus*, *neuralgia*, etc. Mixed with wax, it is highly recommended as a basis for ointments by the same authority.

Oil of Eulachon.—The fish known by the North Pacific Indians under the name of *Eulachon* or *Oulachon*, and by the English as *Hoolakins* or *Candle fish*, the *Thaleichthys pacificus* of scientists, yields a great abundance of an oil which has been proposed as a substitute for cod liver oil. According to the editor of N. R. (1881, 356), this oil first begins to congeal and become opaque at -7° C. (19.4° F.), although authorities state that at ordinary temperatures it grows solid and lard-like. Specific gravity at 15.5° C. (60° F.), 0.907; mixed with one-half its volume of nitric acid, specific gravity 1.37, it develops a beautiful pink color which fades slowly to amber, and after standing fifteen hours it is considerably thickened and its color is changed to a deep amber of a

reddish cast. It contains about 20 per cent. of palmitic and stearic acids, and 60 per cent. of oleic acid and 13 per cent. of an unsaponifiable substance, which resembles the similar constituent of sperm oil. (*T. G.*, Sept. 15, 1884.)

Oil of Euphorbia.—A fixed oil, obtained from the seeds of *Euphorbia Lathyris*, L. (Fam. Euphorbiaceæ), a biennial plant growing wild in this country, though believed to have been introduced from Europe. It is often found near gardens and in cultivated fields, and is generally called *mole plant*, under the impression that moles avoid the ground where it grows. (Pursh.) It is the *caper plant* of England. Like the other species of Euphorbiaceæ, it contains a milky juice, which is extremely acrid, and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in medicine. This may be extracted by expression, or by the agency of alcohol or ether. In the first case, the bruised seeds are pressed in a canvas or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposits upon standing, and by subsequent filtration. By the other process, the bruised seeds are digested in alcohol, or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeiran, however, the oils obtained by these different processes are not identical. That procured by expression is probably the purest.

Oil of euphorbia is colorless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acrimony. Soubeiran has ascertained that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (*J. P. C.*, xxi. 259.) From 40 to 44 parts are obtained by expression from 100 of the seed. It is a powerful purge, but in doses of from five to ten drops is stated by Continental physicians to act kindly upon the bowels. In this country, however, it has been found very uncertain in its effects, and very liable to cause vomiting. (*A. J. P.*, iv. 124.)

Oil of Gynocardia. *Oleum Gynocardia*, Br. *Add. Chaulmoogra Oil.*—The fatty oil expressed from the seeds of *Gynocardia odorata*, R. Br. (*Chaulmoogra odorata*, Roxb.), or *G. Prainii*, Desp. (Fam. Bixaceæ). The origin of the chaulmoogra seed and the oil obtained from it is still a matter of doubt. According to D. Prain the trees growing in the Calcutta Botanical Gardens do not belong to the genus *Gynocardia*, but are probably *Hydnocarpus heterophyllus*, Kurz. The seeds of the *Gynocardia* are said to be essentially different from the chaulmoogra seeds, having the radicle laterally placed, a thinner testa, and when moistened giving off hydrocyanic acid. (*P. J.*, lxvi.) The chaulmoogra seeds are from one to one and a quarter inches long, more or less angular or flattened, and yield upon expression, from 25 to 30 per cent., to ether, about 50 per cent. of oil. The commercial oil is obtained by expression, or sometimes by boiling the crushed seeds with water; is brownish-yellow, with a characteristic odor, acrid taste and acid reaction. "It may fully liquefy only at 42° C. (107.6° F.), resolidifying in different periods and at different temperatures down to 15.5° C. (60° F.). Specific gravity not constant, but usually from 0.930 to 0.954 at 30° to 40° C. (86° to 104° F.). Cold alcohol (90 per cent.) dissolves the greater part of the oil, repeated treatment with warm alcohol (90 per cent.) dissolving the remainder. It is

soluble also in purified ether, chloroform, and carbon bisulphide. It may contain a little non-fatty matter not taken up by these solvents and causing turbidity of the solutions. Twenty drops with one drop of sulphuric acid in a watch-glass acquires a reddish-brown coloration changing to olive-green." Br. *Add. Power & Gornall (Proc. Chem. Soc.*, June, 1904) state that the expressed oil has a specific gravity 0.951 at 25° C. and 0.940 at 45° C.; melting point 22°–23°; saponification value 213, and iodine value 103.2.

John Moss (*P. J.*, x. 251) found in chaulmoogra oil, *gynocardic acid* 11.7, *palmitic acid* 6.3, *hypogæic acid* 4, *cocinic acid* 2.3 per cent. in combination with glyceryl as fats, while gynocardic and palmitic acids were also found in the free state; the activity of the oil he believes to be due to gynocardic acid, and states that the green coloration produced by treating the oil with sulphuric acid (Dymock's test) can also be obtained by treating palm oil in the same manner, yet purified gynocardic acid gives the same green color. *Gynocardic acid* has a yellowish color, forms crystalline plates, melting at 29.5° C. (85° F.), has an acrid burning taste, and is probably of the formula $C_{14}H_{24}O_2$. Power & Gornall (*loc. cit.*) have extracted *chaulmoogric acid*, $C_{18}H_{32}O_2$, crystallizing in leaflets melting at 68° C. Like the oil from which it is derived, the acid is optically active. They consider that this acid belongs to a series $C_nH_{2n-4}O_2$, intermediate between the linolic and the linolenic series. The chaulmoogra seeds are in themselves an article of commerce and are sometimes given internally in place of the oil in doses of six grains (0.4 Gm.). Chaulmoogra oil is said at present to be very largely used in England, being sold by the ton, as a local application to open sores, wounds, sprains, etc., in domestic animals, and to be officially employed in the English cavalry and artillery. It is also said to be employed against bruises, sprains, rheumatism, and stiffness by sportsmen and athletes. In leprosy it is given internally, and also applied regularly and freely externally, and seems to be one of the most useful of known drugs. It has also been given with asserted benefit in various forms of external syphilis, ichthyosis, and in other chronic skin diseases. *Gynocardic acid* is sometimes used as a substitute for chaulmoogra oil internally in doses of from one-half to two grains (0.032–0.13 Gm.) or externally dissolved in oil (1 to 10 or 30). According to J. Moeller, the commercial seed is not the product of *Gynocardia* alone. For a description of seed and plants, see *P. J.*, xv. 321.

Unna has proposed the use of a soap made from the oil as affecting the stomach and intestines less unpleasantly than the oil itself. (See *P. J.*, lxiv. 615.) The dose of the oil is from five to ten minims (0.3–0.6 Cc.), gradually increased, best administered in capsule or in olive oil solution.

Oil of Indian Grass.—The Indian grass oils are at least five in number,—namely, oils of citronella, lemon grass, Indian or Turkish geranium, ginger grass, and vertivert or cus-cus. They are derived from various tropical grasses of the genus *Andropogon*, but there is some confusion as to the particular species from which the individual oils are obtained. These oils are used solely for perfumery. (See *Oils of Citronella and Lemon grass*, pages 1586 and 1589.)

Oil of Jasmine.—This oil is obtained from the flowers of *Jasminum officinale*, L., or common white jasmine, of *J. Sambac*, Solander, and of *J.*

grandiflorum, L. Alternate layers of the fresh flowers, and of cotton saturated with the oil of ben or other fixed oil, are exposed in a covered vessel to the warmth of the sun, the flowers being renewed until the oil becomes impregnated, when it is separated from the cotton by pressure. This method is necessary, as the flowers do not yield their aroma by distillation. According to Gildemeister and Hoffmann, jasmine oil contains 65 per cent. of benzyl acetate, and in addition linalyl acetate, benzyl alcohol, and linalool. The oil is used only as a perfume. W. H. Hall records (*M. S. Rep.*, Jan. 1861) the case of a child poisoned by the fruit of a jasmine, probably the common white species. The symptoms were coma, widely dilated pupil, and snoring respiration, with a cold pale surface, and slow and feeble pulse, followed by violent convulsions, with rigidity of the muscles about the head and throat.

Oil of Kuromoji.—Under this name there have entered commerce two fragrant Japanese oils—one, *Kouro motsi*, said to be obtained from the *Lindera sericea*, and one, *Kuro matsi*, yielded by *Lindera umbellata*. (See Schimmel's Bericht, 1904.)

Oil of Lemon Grass. *Oleum Graminis Citrati*, Br. Add. *Oleum Andropogon Citrati*. Indian Oil of Verbena.—This oil is distilled from *A. citratus*, DC., *A. Schenanthus*, Wall., and probably other grasses of the genus *Andropogon*, as *A. iwarancusa*, Roxb., *A. Calamus*, Royle, *A. Martini*, Roxb. *Andropogon citratus* is a large, coarse-looking grass, cultivated largely in India, the Malay Peninsula, Ceylon, and the neighborhood of Singapore. It grows in light soil, requiring very little care in cultivating, but considerable moisture. The oil is exported in large quantities from Ceylon, India, and adjacent countries. It is a yellowish-brown liquid having a characteristic odor and a pungent taste. "Specific gravity 0.895 to 0.905. It should not rotate the plane of a ray of polarized light more than 3° in either direction in a tube 100 Mm. long. Soluble in alcohol (70 per cent.). If 10 Cc. be well shaken with 50 Cc. of a boiling 30 per cent. solution of sodium hydrogen sulphite, an oily layer separates, which, when cooled to 15.5° C. (60° F.), should not measure more than 3.5 Cc. (absence of more than 35 per cent. of constituents other than aldehydes)." Br. Add. The chief constituent of lemon grass oil is *citral*, $C_{10}H_{16}O$, of which it contains from 70 to 85 per cent. Oil of lemon grass is sometimes used in Eastern countries as a carminative and stimulant in doses of one-half to three minims (0.03–0.2 Cc.). Its sole use is in perfumery.

Oil of Maize.—Our American maize or Indian corn yields a bright golden-yellow oil, of peculiar pleasant odor and taste. It is moderately thick, and has a sp. gr. at 15° C. (59° F.) of 0.916 to 0.924. It consists of olein and palmitin, and solidifies at –10° C. (14° F.). The oil is contained in the germs of the seed alone. Reckoned on the whole weight of the seeds the oil constitutes 11 per cent., of which from 6 to 8 per cent. is extracted; reckoned on the weight of the germ itself, after separation from the starchy body of the seed, the oil amounts to 22 per cent. It is now being extensively produced in the Western United States in connection with the working of starch and glucose factories. It is used as a lubricant and for soap making, but especially as a substitute for cotton seed oil and other adulterations of lard. In 1901 the amount of corn oil exported from the United States was 4,808,545 gallons, and in 1905, 3,108,917 gallons.

Oil of Mexican Lignaloos.—This volatile oil, which is used chiefly on account of its fragrant odor (which has been described as resembling that of a mixture of lemon and jasmine), is said to be obtained by the distillation of the wood of undetermined species. For characters of aloe wood, see *Ph. Post*, 1898; of the oil, see *P. J.*, Aug. 1887.

Oil of Myrcia. *Oleum Myrciæ*. Oil of Bay. "A volatile oil distilled from the leaves of *Myrcia acris* De Candolle (nat. ord. *Myrtaceæ*)." *U. S.* 1890. The commercial oil of bay is a mixture of both heavy and light oils, as G. M. Beringer found the specific gravity of two samples of undoubted purity to be 0.975 and 0.994. (*A. J. P.*, 1887, 286.) Mittmann (*A. Pharm.*, 1889, 529) reported the following constituents: 1, *pinene*; 2, possibly *dipentene*; 3, a polyterpene, probably *diterpene* (insoluble in alcohol); these three in small quantity only; 4, *eugenol*, the chief constituent; and, 5, *methyl-eugenol*, in smaller quantity. It has since been examined (March, 1895) by Power and Kleber, who state that it contains from 60 to 65 per cent. of phenols, of which two were identified: *eugenol*, $C_{10}H_{12}O_2$, and *chavicol*, $C_9H_{10}O$; two phenol esters, *methyl-eugenol*, $C_{11}H_{14}O_2$, and *methyl-chavicol*, $C_{10}H_{12}O$; *phellandrene* and a newly discovered terpene which they name *myrcene*; and *citral*, $C_{10}H_{16}O$. (*Ph. Rund.*, 1895, 60.) The oil was officially described as "a yellow or brownish-yellow liquid, having an aromatic, somewhat clove-like odor, and a pungent, spicy taste. Specific gravity: 0.975 to 0.990 at 15° C. (59° F.). With an equal volume of alcohol, glacial acetic acid, or carbon disulphide, it yields slightly turbid solutions. The alcoholic solution is slightly acid to litmus paper. When mixed with an equal volume of a concentrated solution of sodium hydroxide, it forms a semi-solid mass. If 2 drops of the Oil be dissolved in 4 Cc. of alcohol, and a drop of ferric chloride test-solution be added, a light green color will be produced; and if the same test be made with a drop of diluted ferric chloride test-solution, prepared by diluting the test-solution with four times its volume of water, a light bluish coloration will be produced, which soon disappears. If to 3 drops of the Oil, contained in a small test-tube, 3 drops of concentrated sulphuric acid be added, and, after the tube has been corked, the mixture be allowed to stand for half an hour, a resinous mass will be obtained. On adding to this mass 4 Cc. of diluted alcohol, vigorously shaking the mixture, and gradually heating to the boiling point, the liquid should remain nearly colorless, and should not acquire a red or purplish-red color (distinction from oil of pimenta and oil of cloves)." If 1 Cc. of the Oil be shaken with 20 Cc. of hot water, the water should not give more than a scarcely perceptible acid reaction with litmus paper. If, after cooling, the liquid be passed through a wet filter, the clear filtrate should produce, with a drop of ferric chloride test-solution, only a transient grayish-green, but not a blue or violet, color (absence of *carbolio acid*)." *U. S.* 1890. Oil of bay is not used internally, but solely for making spirit of myrcia or bay rum; the *U. S. P.* 1890 process is given: *Spiritus Myrciæ*. *U. S.* 1890. *Spirit of Myrcia*. *Bay Rum*.—"Oil of Myrcia, sixteen cubic centimeters [or 260 minims]; Oil of Orange Peel, one cubic centimeter [or 16 minims]; Oil of Pimenta, one cubic centimeter [or 16 minims]; Alcohol, twelve hundred

and twenty cubic centimeters [or 41 fluidounces, 122 minims]; Water, a sufficient quantity, to make two thousand cubic centimeters [or 67 fluidounces, 302 minims]. Mix the Oils with the Alcohol, and gradually add Water until the solution measures two thousand cubic centimeters [or 67 fluidounces, 302 minims]. Set the mixture aside, in a well-stoppered bottle, for eight days, then filter it through paper in a well-covered funnel." *U. S.* 1890. The distilled spirit has been abandoned and a formula for its preparation substituted. It will in many cases be found that, even when complying strictly with the directions of the formula, simple filtration will not produce a transparent spirit. The addition to the filter of a small quantity of magnesium carbonate rubbed up with a little of the spirit to a smooth paste will accomplish the object of clarification. For an English formula for bay rum, see *P. J.*, 1896, 468. This was a new official of the *U. S. Pharmacopoeia* of 1860, and was defined as obtained by distilling rum with the leaves of *Myrcia acris*. It had been long in use as a most agreeable and refreshing perfume, and many persons, on account of the name, believed it to be prepared by distilling spirit from the leaves of the bay tree (*Laurus nobilis*). It appears, however, that this was an error. (*A. J. P.*, July, 1861.) A leaf was presented to Maisch, brought from the West Indies, with the information that it was from the tree the leaves of which were used in preparing this spirit. He observed that it had precisely the characteristic odor and taste of bay rum, and on comparing it with the leaves of a twig in the collection of the Academy of Natural Sciences of this city, brought by Griffiths from St. Croix, and labelled as the plant from which bay rum was prepared, found that the two closely corresponded. From the characters of the leaf, Bridges suggested that it might belong to a plant of the family Myrtaceæ, most probably the *Myrcia acris* of De Candolle (see *Myrcia acris*), and there is little room to doubt that *Myrcia acris* is the source of this very agreeable perfume. Bay rum is used chiefly as a refreshing perfume in cases of nervous headache, faintness, and other nervous disorders, either held to the nostrils, or applied on soft linen to the head and forehead. It is also grateful to the feeble and convalescent patient, by being sprinkled on the bed covering or otherwise made to impregnate the air of the chamber. The oil of bay is often adulterated, and is frequently sold by smugglers.

Oil of Neat's-Foot. *Oleum Bubulum.* *Oleum Pedum Tauri.* *Axungia Pedum Tauri.* *Huile (Graisse) des Pieds du gros Bétail.* *Fr. Klauenöl, Ochsen Klauenfett.* *G.*—This formerly official oil is obtained by boiling for a long time the feet of the ox, previously deprived of hoofs. The fat and oil which rise to the surface are removed and introduced into a fresh portion of water, heated nearly to the boiling point. The impurities having subsided, the oil is drawn off, and, if required to be very pure, is again introduced into water, which is kept for twenty-four hours sufficiently warm to enable the fat which is mixed with the oil to separate from it. The liquid being then allowed to cool, the fat concretes, and the oil is removed and strained, or filtered through layers of small fragments of charcoal free from powder. The oil is clear and yellowish in color, of sp. gr. 0.916 at 15° C. (59° F.), and, when properly prepared, inodorous and of a bland taste. It thickens or congeals with great difficulty, and is,

therefore, very useful for greasing machinery. It is also used for softening leather and in grinding metals. It has been given as a substitute for cod liver oil in scrofulous diseases. It is apt to be laxative, and in certain cases proves useful in this way. It is given in the same dose as cod liver oil. (See *Am. J. M. S.*, N. S., xxiv. 498.) It is at present difficult to obtain pure neat's-foot oil in commerce.

Oil of Neroli. *Oleum Aurantii Florum.* *U. S.* 1890. *Oil of Orange Flowers.* *Oleum Naphæ, G.* "A volatile oil distilled from the fresh flowers of the Bitter Orange, *Citrus vulgaris* Risso (nat. ord. *Rutaceæ*). It should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.* 1890.

This oil, official in the *U. S. P.* 1890, is employed for its odor and taste, and is largely used as an ingredient in cologne water, perfumes, etc. The best quality of oil of neroli, as it is universally called in commerce, comes from Nice, and is derived from the flowers of the *Citrus Aurantium*, L., or sweet orange, by distillation with water; this is called *néroli pétale*. The next quality is obtained in the same way, but by using the blossoms of the *Citrus Bigaradia*, Loisel. (*C. amara* (L.), Lyons), or bitter orange: this is called *néroli bigarade*; while an inferior sort, *essence de petit grain*, is made by distilling the leaves and unripe fruit. This should not be classed with neroli, as it is unworthy of the name. *Oil of petit grain citronnier* is a fragrant oil, distilled from the leaves and twigs of the lemon tree; it closely resembles the *essence de petit grain* which is made from the orange leaves and fruit. (*C. D.*, 1897, 53.)

Properties.—It was officially described as "a yellowish or brownish, thin liquid, having a very fragrant odor of orange flowers, and an aromatic, somewhat bitter taste. Specific gravity: 0.875 to 0.890 at 15° C. (59° F.). Soluble in an equal volume of alcohol, the solution being neutral to litmus paper. If a little alcohol be poured on the surface of the oil, and the mixture gently undulated, a bright, violet fluorescence will usually be observed. In contact with a saturated solution of sodium bisulphite it assumes a handsome and permanent purplish-red color." *U. S.* 1890. The greater part of the oil is a hydrocarbon, distilling at from 185° to 195° C. (365°–383° F.), with which is a small amount of the crystalline solid called *neroli camphor*. According to Flückiger, this is a neutral, inodorous, tasteless substance, fusing at 55° C. (131° F.). According to Semmler (*Ber. d. Chem. Ges.*, 26, 2711), the oil contains about 20 per cent. of limonene, 30 per cent. of linalool, $C_{10}H_{18}O$; 40 per cent. of linalyl acetate, and 3 per cent. of geraniol. *Schim. Rep.*, April, 1897, mentions a small amount of a paraffin as also present. Noel distinguishes the different volatile oils of the orange tribe by shaking five drops of the oil with one Cc. of pure concentrated hydrochloric acid. After one minute seven or eight Cc. of 90 per cent. alcohol are added, whereby the color is changed, and increased or decreased according to the extent of the adulteration. It is obvious that to use effectually such a test requires special education. (See *Proc. A. Ph. A.*, 1887.)

Under the name of *nerolin* an artificial product has been placed upon the market in the form of a white crystalline powder, soluble in alcohol and fixed oils and almost insoluble in water. It is used by soap makers as a substitute

for oil of neroli, and is said to be ten times as strong. This compound is said to be the *ethyl ether of β -naphthol*. (Ber. d. Chem. Ges., 1893, 2706.) It is also used in the manufacture of eau-de-Cologne with advantage instead of neroli oil. (Schim. Rep., April, 1893.) Oil of neroli of excellent quality is now produced artificially; Schimmel & Co. state that it contains pinene, camphene, dipentene, terpineol, phenyl, acetic acid, benzoic acid, decyl aldehyde, and linalool.

Oil of Palm. *Huile (Beurre) de Palme*, Fr. *Palmöl*, *Palmbutter*, G.—This highly valuable fixed oil is the product of *Eleis guineensis*, Jacq., a palm growing on the western coast of Africa, and cultivated in the West Indies and South America. It is among the handsomest trees of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia and other places on the African coast, though prepared also in the West Indies, Cayenne, and Brazil. It is not improbable that various species of *Palmaceæ* contribute to the supply of this article of commerce. At present the chief ports for its shipment are Cape Palmas and Lagos, prima and secunda Lagos being the choicest varieties. The annual export from the African coast now reaches 50,000 tons, of which the bulk goes to England. The importation into the United States amounted in 1903 to nearly 19,000 tons, but fell off in 1904 to about 10,000 tons.

Palm oil has the consistence of butter, a rich, orange-yellow color, a sweetish taste, and an agreeable odor, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid and of a whitish color. It melts with the heat of the hand, and when perfectly fluid passes readily through blotting paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. Its constituents are *tripalmitin* and *triolein*, $C_{5}H_5(C_{15}H_{31}O_2)_3$ and $C_3H_5(C_{15}H_{31}O_2)_3$. The *tripalmitin* is converted into *palmitic acid* by superheated steam, with liberation of glycerin. It appears also that a considerable proportion of this acid, together with some glycerin, exists uncombined in the oil, as ascertained by Pelouze and Boudet; so that the changes which are effected in oils, through the agency of alkalies, in the process of saponification, take place, to a certain extent, spontaneously in palm oil. (J. P. C., xxiv. 389.) Hence it is more easily saponified than any other fixed oil. Preparatory to saponification, it may be bleached rapidly, according to J. J. Pohl, by heating it quickly to 240° C. (464° F.) and keeping it for ten minutes at that temperature. It loses for a time its peculiar odor by the process, acquiring an empyreumatic one; but this after a while ceases to be perceived, and the characteristic odor returns. (See A. J. P., xxvii. 346.) Englehart bleaches it in the following manner. 1000 lbs. of the oil are heated in a boiler to 62.2° C. (144° F.) and kept at that temperature until the next day, when it is decanted into a clean vessel, and cooled to a point between 38.6° C. (98° F.) and 40° C. (104° F.). In another vessel 15 lbs. of potassium dichromate are dissolved in 45 lbs. of boiling water, and, when the solution is partially cooled, 60 lbs. of hydrochloric acid are added. This solution is then mixed with the oil, and briskly agitated. In five minutes the color changes to green, through the

reduction of the chromic acid, and, with a continuation of the agitation, the chromium oxide separates, and then nothing more is necessary than washing with water to get the oil colorless. (A. J. P., 1868, 333.) Palm oil is said to be frequently imitated by a mixture of lard and suet, colored with turmeric, and scented with Florentine orris. It is much employed in the manufacture of toilet soap, which retains its pleasant odor. Palm oil is emollient, and has sometimes been employed in friction or embrocation, though not superior for this purpose to many other oleaginous substances.

Oil of Patchouli.—This oil is distilled from the leaves of the plant, *Pogostemon heyneanus*, Benth. (*P. Patchouly*, Pelletier), or *Patchouli Balm* (Fam. Labiate). The plant is cultivated at Singapore and other Eastern localities and has an interesting history. The drug was first offered at public sale in London in 1844; it is now imported for European consumption in immense quantities. It is believed by the Arabs, Chinese, and Japanese to possess prophylactic powers. The oil as found in commerce is of two kinds. The best is that distilled in the East in the neighborhood of the patchouli plantations, from selected fresh leaves; the other kind is distilled in Europe from imported leaves; the latter often arrive in a more or less damaged condition, and are frequently adulterated. Oil of patchouli is a thick, brownish-yellow oil with a green tint, and was shown by Gladstone to contain *cærulein*, an intensely blue compound found in oils of absinthium, calamus aromaticus, matricaria, achillea, etc. The oil has the sp. gr. 0.970 and is lævo-rotatory. It deposits a solid, *patchouli alcohol*, $C_{12}H_{26}O$, which crystallizes in hexagonal prisms, melts at 56° C. (132.8° F.), and boils at 206° C. (402.8° F.), while *cadinene*, $C_{15}H_{24}$, remains; oil of cedar and oil of cubeb are frequently used to adulterate the oil. They may be detected by fractional distillation. Oil of patchouli is used in perfumery mainly for its valuable property of conferring upon other odors lasting qualities; its characteristic and persistent odor when uncombined is usually not popular among Caucasians.

Oil of Sesame. *Oleum Sesami*, U. S. 1890. Under the name of *Oleum Sesami* the Br. Add. recognizes sesame oil with the following official characteristics and tests. "Specific gravity 0.921 to 0.924. It congeals at a temperature of 23° F. (5° C.). If 10 cubic centimetres be treated with 10 cubic centimetres of *hydrochloric acid* containing 0.6 gramme of *pyrogallol*, and the mixture be shaken vigorously and then set aside for one minute, two layers will be formed. The upper oily layer is to be carefully removed by means of a pipette; the lower acid layer is to be boiled for five minutes, when it will gradually assume a color which is purple by transmitted light and blue by reflected light." The oil was official in the U. S. P. 1890 and defined as follows: "A fixed oil expressed from the seed of *Sesamum indicum* Linné (nat. ord. *Pedaliaceæ*)." U. S. 1890.

Benne Oil, or *Teel Oil*, is inodorous, of a bland, sweetish taste and a neutral reaction, and will keep long without becoming rancid. Flückiger finds that 76 per cent. of the oil consists of olein, and that the solid portions yield on saponification palmitic, stearic, and myristic acids. The oil also contains a small quantity of what is probably a resinoid substance, which may be removed by gla-

cial acetic acid or alcohol. It bears some resemblance to olive oil in its properties, and may be used for similar purposes. It is not a drying oil. Villavecchia and Fabris (*Zeit. für Ang. Chem.*, 1893, 505) have investigated sesame oil, and find, in addition to the main constituents before mentioned, a higher alcohol of the formula $C_{25}H_{44}O$, fusing at $137^{\circ} C.$ ($278.6^{\circ} F.$), a finely crystallizing substance of the formula $C_{11}H_{12}O_3$, fusing at $123^{\circ} C.$ ($253.4^{\circ} F.$), which substance they name *sesamin*, and a thick uncrystallizable oil, non-nitrogenous, which is the cause of the cherry-red coloration which sesame oil shows with hydrochloric acid and sugar. Tocher (*P. J.*, 1893, 700), after analyzing *sesamin* and determining its molecular weight by Raoult's method in benzene and glacial acetic acid, maintains that its formula should be $C_{18}H_{32}O_6$. Tocher, as quoted by Lewkowitsch (*Chem. Anal. of Oils, Fats, and Waxes*, 2d ed., 389), also believes that the higher alcohol mentioned is cholesterol. "Specific gravity, 0.919 to 0.923 at $15^{\circ} C.$ ($59^{\circ} F.$). When cooled to $-3^{\circ} C.$ ($26.6^{\circ} F.$) it becomes thick, and at $-5^{\circ} C.$ ($23^{\circ} F.$) it congeals to a yellowish-white mass. Concentrated sulphuric acid converts it into a brownish-red jelly. If 5 Cc. of the Oil be shaken with an equal volume of concentrated hydrochloric acid, the latter will usually assume a bright emerald-green color, especially if the Oil has been exposed for some time to the action of air and light; and, on the subsequent addition of about 0.5 Gm. of sugar, and again shaking the mixture, a blue color, changing to violet, and finally to deep crimson, will be produced." *U. S.* 1890. Soltzien recommends stannous chloride solution for testing benne oil. (*Proc. A. Ph. A.*, 1897, 195.) According to Schaedler, if one Cc. of pure benne oil is shaken with one Cc. of pure hydrochloric acid, sp. gr. 1.125, and one gramme of cane sugar, a rose-red color is developed in fifteen minutes, changing to violet in twenty-five minutes, and increasing in intensity until, after five hours, the acid has assumed a violet color corresponding in intensity to that of a solution of iodine in carbon disulphide or in chloroform. In the case of all other fixed oils, this color reaction does not begin until after three-quarters of an hour. Olive and almond oils containing as little as one-fourth per cent. of benne oil exhibit the reaction in from twenty to twenty-five minutes. The failure of some experimenters to find the reactions available rests upon the fact that they searched for the color in the oil, and not, as they should have done, in the acid. (*A. Pharm.*, 1887, p. 185.) Benne oil was known to the ancient Persians and Egyptians, and is esteemed by the modern Arabs and other people of the East both as food and as an external application to promote softness of the skin. It is laxative in large doses.

Oil of Turtle. *Turtle Oil.*—In South America an oil is prepared from the eggs of turtles, and in the Seychelle Islands and in Jamaica from the fat of the turtle itself. These oils are said to be of equal value with cod liver oil for strumous persons and others in whom the nutritive processes are defective. (See *P. J.*, vol. xv. 573.) It is stated that 50,000 gallons are sent to Pará yearly from the Orinoco, the Amazon, and the Rio Negro, and that 60,000 gallons are consumed by the tribes who prepare the oil. The Seychelle Islands are said to produce 6000 gallons of oil yearly.

Oil of Wood. *Wood Oil. Gurjun Balsam. Balsamum Dipterocarpi.*—In the *P. J.* for August, 1854 (p. 65), appeared an account by Charles Lowe of

Manchester, of a "new variety of balsam of copaiba," derived from the East Indies. In a subsequent communication to the same journal (1856, 321) from Daniel Hanbury, it appears that this product, though offered for sale in the London market as *balsam of copaiba*, is known in India under the names of *wood oil* and *gurjun balsam*. Considerable quantities had been imported from Maulmain, in Burmah, specimens of a similar drug had been received from Canara and Tenasserim, and it appears to be widely diffused in the Indian markets.

This liquid is obtained from *Dipterocarpus turbinatus*, Gaertn. f. (*D. laevis*, Buch. Ham.) (Fam. Dipterocarpaceæ), a very large gregarious tree which forms forests in Pegu and other parts of Farther India. A large notch is cut in the trunk of the tree, between two and three feet from the ground, and a fire made so as to char the wound. The juice then begins to flow, and is received in suitable vessels. Every three or four weeks the charred surface is cut off and burned anew. A single tree sometimes yields forty gallons in a season. Other species of *Dipterocarpus* afford a similar product, and hence probably the difference which has been observed in the specimens examined. It is at first turbid, but may be clarified either by filtration or deposition. After filtration, wood oil is a clear, dark brown liquid, of the sp. gr. 0.964 (Hanbury), and, in consistence, odor, and taste, bears a close resemblance to copaiba. It is soluble in two parts of alcohol of the sp. gr. 0.796, with the exception of a very small proportion of darkish flocculent matter, which subsides on standing. According to Lowe, it contains 65 per cent. of volatile oil, 34 of resin, and 1 of acetic acid and water. A characteristic property noticed by Lowe, by which it may be distinguished from copaiba, is that, when heated in a closed vial to $266^{\circ} F.$ ($230^{\circ} F.$, Lowe), it becomes slightly turbid and coagulates, so that the vial may be inverted without changing the position of its contents, and this consistence is retained when the liquid cools. By a gentle heat with agitation the fluidity returns; but the liquid again coagulates if heated to $266^{\circ} F.$ According to D. Brandis, this property of coagulation is characteristic of the wood oil from *D. alatus*, Roxb. (*P. J.*, xxv.), a wood oil which is further to be distinguished by the greenish opalescence of its surface.

Guibourt states that wood oil does not solidify, like copaiba, with one-sixteenth of magnesia, and the two separate on standing. (*J. P. O.*, xxx. 192.) De Vrij of Rotterdam, proposes the reaction of benzene with wood oil and copaiba respectively as a test to distinguish them. With an equal volume of the wood oil, benzene forms a turbid mixture, from which, after a long time, a resinous matter is deposited in flocculi; with copaiba it forms a transparent solution. (*P. J.*, 1857, 374.) The volatile oil from gurjun balsam is a yellow, somewhat thick liquid, of sp. gr. 0.915 to 0.930, and has at times a high optical rotation, viz., -35° to -130° . The oil boils in larger part at 255° to $256^{\circ} C.$ (491° – $492.8^{\circ} F.$) and consists of a sesquiterpene, $C_{15}H_{24}$. With hydrochloric acid it yields a deep blue color. The resin left after distilling off the volatile oil is essentially *gurjunio acid*, $C_{22}H_{34}O_4$. This when purified dissolves readily in ether and strong alcohol, and slowly in benzene. It melts at $220^{\circ} C.$ ($428^{\circ} F.$) and congeals again at $180^{\circ} C.$ ($356^{\circ} F.$). Flückiger has also described a neutral resin from gurjun

balsam, which is insoluble in caustic potash, fuses at 126° C. (258.8° F.), and is of the composition $C_{28}H_{46}O_2$. Flückiger (*A. Pharm.*, 1876, 420) noticed that wood oil may be recognized by the violet color it assumes if dissolved in twenty parts of carbon disulphide and mixed with a drop of a cold mixture of equal parts of concentrated sulphuric and nitric acids. A liquid is much employed in India for painting ships, houses, etc., which is also called *wood oil*; this is obtained from a different source, being a fixed oil derived from the seeds of *Aleurites cordata*, R. Br. According to O'Shaughnessy, the oil of dipterocarpus is little inferior to copaiba in the diseases for which that medicine is employed. T. B. Henderson has found it very useful in *gonorrhea*, given in the dose of a teaspoonful two or three times a day, uncombined. (*M. T. G.*, 1865, 571.) It probably has a remedial influence on diseased mucous membranes similar to the different turpentine, which it appears to resemble in composition. The juice may be given in emulsion, in doses of from fifteen to forty minims (0.9–2.5 Cc.); the volatile oil from ten to thirty minims (0.6–1.8 Cc.).

East India wood oil, or gurjun balsam, must not be confounded with *Chinese wood oil* or *tung oil*, a fixed oil obtained from the euphorbiaceous *Aleurites cordata*, R. Br. This oil has a specific gravity at 15.6° C. (60° F.) of 0.94015, and does not congeal at a temperature of –22.2° C. (–8° F.). If a drop of it be added to nitric acid it changes on heating into an orange-yellow solid. When a drop of sulphuric acid is brought in contact with the oil the latter apparently solidifies around the acid, forming a black envelope, which grows in size and gradually absorbs and acts upon so much of the surrounding oil as to assume the appearance of an irregular, large, dried currant. *Chinese wood oil* saponifies readily with potassium hydroxide, two hundred and eleven parts of the potassium hydroxide being required for a thousand parts of oil. For details see *P. J.*, vol. xv. (See also *Proc. A. Ph. A.*, 1897, 677.) It is much used in China and Japan as a natural varnish for wood work, having notable drying properties. Over 60,000 kilogrammes are said to be sent yearly from Hankow, on the Yang-tse-Kiang, in the interior of China, to Chinese sea-ports. The seeds of the tung oil plant are said to be poisonous, and are used in China for killing rats, and also to produce vomiting, especially in would-be opium suicides.

Oil of Ylang Ylang. *Cananga Oil.* *Oleum Anonae.* *Oleum Unonae.*—This is a volatile oil obtained from the flowers of *Cananga odorata*, Hook. f. and Thoms (Fam. Anonaceae), a large tree inhabiting most parts of Southern Asia. According to Schimmel & Co. (*Schim. Rep.*, April, 1897), it contains pinene, linalool, geraniol, esters of acetic and benzoic acids, cadinene, and para-cresol-methyl ester. It is used only as a perfume. (See *N. R.*, April, 1881.) The so-called *Macassar hair oil* is said to be a solution of it in coconut oil. (See *A. J. P.*, 1881, 123; also *A. J. P.*, 1893, 529.)

Ointment of Casein. *Unguentum Caseini.* *Caseinsalbe*, G.—Made by dissolving dried and powdered casein in 50 parts of a solution containing 0.345 part of potassium hydroxide and 0.895 part of sodium hydroxide. To this add 7 parts of glycerin, 0.5 part of phenol and finally 21 parts of petrolatum. When this has been thoroughly incorporated enough water is added to make 100

parts. It has the consistence of thick cream, is incompatible with acids and acid salts, but mercury, tar, balsam of Peru, zinc oxide, resorcinol, pyrogallol, and ichthyol may be incorporated with it.

Ointment of Cucumber. *Cucumber Ointment.* An emollient ointment, prepared from the common cucumber (fruit of *Cucumis sativus*, L., Fam. Cucurbitaceae), has been considerably employed in *irritated states of the skin*. The following is the mode of preparing it, recommended by Procter. Take of green cucumbers 7 pounds avoirdupois, pure lard 24 ounces, veal suet 15 ounces. Grate the washed cucumbers to a pulp, express, and strain the juice. Cut the suet into small pieces, heat it over a water bath till the fat is melted out from the membrane; then add the lard, and, when melted, strain through muslin into an earthen vessel capable of holding a gallon, and stir until thickening commences, when one-third of the juice is to be added, and the whole beaten with a spatula till the odor has been almost wholly extracted. The portion which separates is to be decanted, and the remaining two-thirds of the juice is to be consecutively incorporated and decanted in the same manner. The jar is then closely covered and placed in a water bath, until the fatty matter entirely separates from the juice. The green coagulum floating on the surface is now removed, and the jar put in a cool place that the ointment may solidify. The crude ointment is then separated from the aqueous liquid on which it floats, melted and strained, and placed in glass jars, which must be kept closely sealed. A layer of rose water upon its surface will favor its preservation. A portion may be triturated with a little rose water until white and creamy, and put into a separate jar for present use. (*A. J. P.*, xxv. 409.)

Emile Mouchon prepares the ointment by obtaining the juice mixed with a little alcohol, and incorporating this with benzoinated lard and stearin. He directs 16 parts of the cucumber to be reduced to a pulp, 1 part of alcohol of 36° B. (87 per cent. vol.) to be added, and the mixture to be placed on the diaphragm of a percolator. Twenty-four hours afterwards 10 parts of the liquid are obtained of 19° B. Of this liquid 6 parts are to be incorporated with 37.5 parts of benzoinated lard and 12.5 of stearin; the fatty matters having been previously melted together by means of a water bath, and beaten vigorously on cooling. The liquid is to be added before the completion of the beating, which should then be continued until the whole becomes as light and white as possible. The benzoin and alcohol enable the ointment to keep a long time. (*J. P. C.*, Juillet, 1864, 41.) We prefer to make this ointment by incorporating one part of distilled spirit of cucumbers with seven parts of benzoinated ointment. The spirit is made by distilling a mixture of one part of grated cucumbers with three parts of diluted alcohol, retaining the first two parts or distillate which come over. This spirit is permanent, and ointment or cream made from it keeps well.

Olibanum. *Thus.* *Oliban, Encens*, Fr. *Weihrauch*, G.—Olibanum, the *frankincense* of the ancients, was erroneously ascribed by Linnaeus to *Juniperus phanicea*, L. (*J. lycia*, L.). There are two varieties of olibanum, one coming to Europe from the Mediterranean, and the other directly from Calcutta. These varieties were formerly considered distinct, but recent researches indicate

their common origin. In 1843 Captain Kempthorne, of the East India Company's navy, saw the olibanum tree growing upon the mountains, on the African coast, between Bunder Maryah and Cape Guardafui. According to his statement, it grows on the bare marble rocks composing the hills of that region, without any soil or the slightest fissure to support it, adhering by means of a substance thrown out from the base of the stem. This rises forty feet, and sends forth near the summit short branches, covered with a bright green, singular foliage. The juice, which exudes through incisions made into the inner bark, has at first the color and consistence of milk, but hardens on exposure. (*P. J.*, iv. 37.) Sir William J. Hooker says that the African olibanum is derived from *Boswellia papyrifera*, Hochst. (*Plösslea floribunda*, Endl.), one of the Burseraceæ; but thinks it highly probable that it is furnished by more than one species. (*Ibid.*, 1859, 217.) Bennett, of the British Museum, has also identified Kempthorne's specimens as *P. floribunda*. But in 1847 Carter described very closely the olibanum district, and procured living specimens, the descendants of which appear still to flourish in the "old gardens" of the Bombay Agri-Horticultural Society. Birdwood asserts (*Tr. Linn. Soc.*, xxvii.) that no olibanum is obtained in India, all coming from a coast district of Arabia (the same district as that described by Theophrastus), and being the product of a new species of *Boswellia*, *B. Carterii*, Birdwood. It is very likely that several species of *Boswellia* furnish the olibanum of commerce,—viz., *B. Carterii*, Birdw. (furnishes what is known as *Luban Bedoui* or *Luban Sheheri*), and *B. frereana*, Birdw. (furnishes *Luban Meyeti* or *Luban Matti*). It appears that the resin of *B. papyrifera*, Hochst., is not gathered at all. The product of *B. serrata*, Roxb. (known as *Salaigugul*), is not sent into general commerce, but is employed medicinally only in India.

The Arabian or African frankincense is in the form of yellowish tears, and irregular reddish lumps or fragments. The tears are generally small, oblong or roundish, not very brittle, with a dull and waxy fracture, softening in the mouth, and bearing much resemblance to mastic, from which, however, they differ in their want of transparency. The reddish masses soften in the hand, have a stronger taste and odor than the tears, and are often mixed with fragments of bark and small crystals of calcium carbonate which are visible under the microscope.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamic resinous odor, and an acrid, bitterish, somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame and a fragrant odor. Triturated with water, it forms a milky imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent. Tschirch (*Harze und Harzbehälter*, 1900, p. 253) has made a thorough study of olibanum and determined all of its constituents with care. Alcohol extracts 72 per cent., consisting of resins 65 per cent. and volatile oil 6 per cent.; water soluble gum, 20 per cent.; bassorin, 6-8 per cent.; plant residue 2-4 per cent. The resins were composed of *boswellic acid*,

$C_{32}H_{52}O_4$, a resin acid of which well crystallized salts were obtained, and *olibanoresin*, $C_{14}H_{22}O$, a neutral resin.

In the essential oil Wallach identified *l-pinene* and dipentene, while the chemists of Schimmel & Co. found in addition *phellandrene*.

W. F. Daniell has described an odorless product, used as *frankincense* in Sierra Leone, and obtained from a large tree, growing in the mountainous districts of that region. The tree has been described by J. J. Bennett in *P. J.*, 1854, 251, as *Daniella thurifera* (Fam. Leguminosæ). According to Daniell, the juice exudes through openings made by an insect, and, concreting in connection with the woody particles resulting from the boring of the insect, falls at length to the ground, where it is collected by the negroes. (See *A. J. P.*, xxvii. 338.)

Olibanum is stimulant like the other gum-resins, but is now very seldom used internally. According to Delieux of Toulon, however, it affords a cheap, efficient substitute for the balsams of Tolu and Peru. It appears to act more favorably when combined with a little soap. Delieux has also obtained advantage from the inhalation of its fumes, when heated, in chronic *bronchitis* and *laryngitis*. (*B. G. T.*, Fév. 28, 1861.) It is chiefly employed for fumigation, and in unofficial plasters. *Dose*, fifteen grains (1.0 Gm.), which may be increased to a drachm (3.9 Gm.) or more.

Oliver Bark. *Oliveri Cortex.* *Black Sassafras.* The dried bark of *Cinnamomum Oliveri*, Bailey (*Proc. Linn. Soc. of New South Wales*, July 28, 1897, part 2). "In flat pieces usually about eight inches (two decimetres) in length, and one and a half inches (thirty-seven millimetres) in width. It is covered with a coarsely granular periderm of a deep orange-brown color marbled with patches of a yellowish-brown hue; the tissues beneath the periderm are of a deep umber-brown color. The inside of the bark is of an umber-brown color, and has a close satin-like surface marked with very fine stria. It has a close fracture, slightly fibrous in the liber portion. Odor aromatic and spicy, recalling sassafras and camphor; taste agreeably spicy and camphoraceous." *Br. Add.* "*Tinctura Oliveri Corticis* (*Tincture of Oliver Bark*).—Oliver Bark, in No. 40 powder, 2 oz. (or 100 Gm.); alcohol (60 per cent.), a sufficient quantity. Moisten the powder with one fluid ounce (or 50 Cc.) of the alcohol, and complete the percolation process. The resulting tincture should measure one pint (or 1000 Cc.)." *Br. Add.* *Dose*, one-half to one fluidrachm (1.8-3.75 Cc.).

Omphalea.—According to Calmody, the government chemist in Trinidad, the seeds of the *Omphalea megacarpa* yield an oil which acts as a brisk cathartic in about three hours after taking, without pain or much continuance. (*P. J.*, Feb. 1898.)

Onion. *Ocea.*—The bulb of *Allium Ocea*, L. (Fam. Liliaceæ). Fourcroy and Vauquelin obtained from the ordinary onion a white acrid volatile oil containing sulphur, albumen, much uncrystallizable sugar and mucilage, phosphoric acid both free and combined with lime, acetic acid, calcium citrate, and lignin. The expressed juice is susceptible of the vinous fermentation. The oil is essentially the same in chemical composition as the oil of *Allium sativum*, L., and consists largely of allyl sulphide (C_6H_5S). (See *A. Pharm.*, 1892, 434.) Perkin and Hummel found *quercetin* in the outer skin of onion bulbs, and the skins have been used in dyeing.

By virtue of its volatile oil the onion taken in moderate quantities is a stimulant to the stomach and promotes digestion, but in large quantities is apt to cause gastric uneasiness. It is slightly rubefacient, said to be diuretic, and belongs among those expectorants to be employed in the advanced stages of subacute *bronchitis* or in chronic *bronchitis*. Remarkable physiological powers have been attached to it by various investigators. As the result of a very elaborate experimental study, Alfred K. Pilacki reached the conclusion that taken freely it depresses nitrogenous metabolism; a conclusion directly opposite to that of Popoff, whose studies led him to the belief that it increases nitrogenous change in the body. It can scarcely be doubted that any apparent influence which it may exert in the direction spoken of is secondary to its action upon digestion.

Onion poultices are somewhat effective as a counter-irritant and nerve stimulant in cases of *bronchitis* or *pneumonia* in young children, with nervous symptoms. According to M. V. Pogorelsky, a decoction made with the outer reddish skin of the bulb is widely used in Russia for the production of abortion. He attributes the emetic effect to the presence of allyl sulphide. One or two tumblerfuls of the concentrated dark brown or dark red infusion are taken at a dose.

Ononis. *Ononis spinosa*, L.—Reinsch obtained from this plant *ononin*, $C_{30}H_{34}O_{13}$, a glucoside. *Onocerin*, a di-secondary alcohol, $C_{26}H_{42}(OH)_2$, was isolated by Thoms, who proposed to change its name to *onocol*. (*A. Pharm.*, 1897, 28.)

Ophioxylon. *Rauwolfia serpentina*, Benth. ex Kurz. (*Ophioxylon serpentinum*, L.) (Fam. Apocynaceæ).—In the root of this plant, which is used in East India as a purge and anthelmintic, Wefers-Bettink found a yellow crystalline principle, *ophioxylin*, melting at $72^{\circ} C.$ ($161.6^{\circ} F.$), and possessing the formula $C_{16}H_{12}O_6$; also a volatile oil. (*A. J. P.*, 1890.)

Opopanax.—A concrete juice sometimes ascribed to *Opopanax hispidum*, Griseb. (*Pastinaca Opopanax*, L., *O. Opopanax* (L.), Lyons). This species of parsnip has a thick, yellow, fleshy, perennial root, which sends up annually a strong branching stem, rough near the base, about as thick as a man's thumb, and from four to eight feet in height. The leaves are variously pinnate, with long sheathing petioles, and large, oblong, serrate leaflets, of which the terminal one is cordate, others are deficient at their base upon the upper side, and the whole are hairy on their under surface. The flowers are small, yellow, and form large flat umbels at the termination of the branches. The plant is a native of the Levant, and grows wild in the south of France, Italy and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the *opopanax* of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice, as that which has been collected from the plant in France, though similar to *opopanax*, is of inferior quality. The drug is brought from Turkey. It is said to come also from the East Indies; but Ainslie states that he never met with it in any Indian medicine bazaar. The method of its production is not known with any certainty.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow color, speckled with white on the outside, paler within, and, when broken, exhibiting white pieces intermingled with the mass. Its odor is strong, pecu-

iar, and unpleasant, its taste bitter and acrid. Its sp. gr. is 1.622. It is inflammable, burning with a bright flame. In chemical constitution it is a gum-resin, with an admixture of other ingredients in small proportion. The results of its analysis by Pelletier were, from 100 parts, 33.4 of gum, 42 of resin, 4.2 of starch, 1.6 of extractive, 0.3 of wax, 2.8 of malic acid, 9.8 of lignin, 5.9 of volatile oil and loss, with traces of caoutchouc. Subsequently, Tschirch found *opopanax* to consist of resin, 19 per cent., ethereal oil, 6.5 per cent.; gum and plant tissues, 70 per cent.; water and loss, 4.5 per cent. (*A. Pharm.*, 1895, 209.) Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky emulsion, which deposits resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavor; but only a very minute proportion of oil can be obtained in a separate state. *Opopanax* was formerly employed, as an antispasmodic and deobstruent, in *hypochondriasis*, *hysteria*, *asthma*, and chronic visceral affections, and as an emmenagogue; but it is now scarcely ever used. Dose, ten to thirty grains (0.65–2.0 Gm.).

Opuntia. *Opuntia Opuntia* (L.), Coul. (*O. vulgaris*, Mill.) (Fam. Cactaceæ.) *Prickly Pear*, *Figue de Barbarie*, Fr. *Indische Feige*, G.—For analyses of fruit of this cactus, see *A. J. P.*, 1884, 3, and 1896, 170.

Orange Red. *Orange Mineral.* *Sandix*.—Red lead oxide, prepared by calcining lead carbonate. It is of a lighter color than *minium*, and is used as a pigment.

Orcin. *Dihydroxytoluene.* $C_6H_3(CH_3)(OH)_2$. This is a white stable powder, of a peculiar sweetish taste and aromatic odor, crystallizing with one molecule of water. It is easily soluble in water, alcohol, and ether, and has a sweet taste. It melts at $56^{\circ} C.$ ($132.8^{\circ} F.$) when it contains water, but, deprived of this, melts at $107^{\circ} C.$ ($224.6^{\circ} F.$). It boils at $290^{\circ} C.$ ($554^{\circ} F.$). It is said to resemble resorcinol in its local action and to be useful in the same class of skin diseases. According to J. Andeer (*Med. Chron.*, Dec. 1885), it is distinctly antiseptic, and in poisonous doses produces death by a direct action upon the heart muscle.

Oreodaphne. *Umbellularia californica* (Arnott), Nutt. *Oreodaphne californica*, Nees. *Tetranthera californica*, Hook. and Arn. *Litsea californica*, Benth. (Fam. Lauraceæ).—The *California Bay Laurel* is an evergreen tree of considerable size, rather abundant throughout the State. Its wood is much prized on account of the beauty of its grain and its immunity from the attacks of insects. The leaves yield about 4 per cent. of a neutral, straw-colored, limpid volatile oil, which has a warm camphoraceous taste and a pungent aromatic odor, resembling somewhat that of a mixture of oils of nutmeg and cardamom. It is soluble in 1000 parts of water, and in alcohol and ether in all proportions. It is said, when inhaled, to cause dizziness and headache. Its chemical characters have been studied by John P. Heamy. (*A. J. P.*, 1875, 105.) He finds it to consist of a pure hydrocarbon, sp. gr. 0.894, boiling at $175^{\circ} C.$ ($347^{\circ} F.$), and an oxygenated pungent portion, which boils at $210^{\circ} C.$ ($410^{\circ} F.$). This he calls *oreodaphnol*. *Oreodaphnene* was obtained by distilling *oreodaphnol* with glacial phosphoric acid. For the reactions, see Heamy's paper.

Orexin. *Phenyldihydrochinazoline Hydrochloride.* $C_9H_4 \left\{ \begin{array}{l} CH_2.N.C_6H_5 \\ N=CHCl \end{array} \right.$. A complex derivative of quinoline. It forms colorless, odorless, lus-

trous crystals with bitter, pungent taste, freely soluble in hot water. Orexin was first brought forward by F. Penzolt as a true stomachic. It appears to be practically free from toxic properties, two grains of it per pound not being sufficient to kill a rabbit. It appears to be a very active remedy in those cases of failure of appetite in which simple bitters are indicated, and to be contra-indicated by hyperacidity of the stomach, gastric catarrh and gastric ulcer.

The *tannate* is affirmed to be more efficient than the hydrochloride, which salt it has practically replaced in the market. The tannate is a yellowish powder, tasteless, odorless, insoluble in water, freely soluble in acid solutions. It is very highly praised in all forms of *atonic dyspepsia*, *loss of appetite* in convalescence, and similar conditions. It is affirmed also to be very useful in the treatment of *vomiting* following the use of narcotics, such as opium, chloroform, etc. It is chemically incompatible with iron salts. It is best administered in the form of powder, five to twelve grains (0.32–0.78 Gm.) given in capsules, one to two hours before meals.

Origanum. *Wild Marjoram. Marjolaine sauvage, Fr. Wilder Majoran (Meiran), G.*—Two species of *Origanum* have been used in medicine, *O. Majorana*, L., or *sweet marjoram*, and *O. vulgare*, L., or common marjoram. The former grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe and in the United States. Some authors, however, consider *O. majoranoides*, Willd., which is a native of Barbary, and closely allied to *O. Majorana*, as the type of the sweet marjoram of our gardens. This is by others considered to be simply a form of *O. vulgare*, L. *Sweet marjoram* has a pleasant odor, and a warm, aromatic, bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a volatile oil. It is tonic and gently excitant, but is used more as a condiment than as a medicine. In domestic practice its infusion is employed to hasten the tardy eruption in *measles* and other exanthematous diseases.

The plant is a native of Europe and America. In this country it grows along the roadsides, and in dry stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but it is not very abundant, and is seldom collected for use. It has a peculiar, agreeable, aromatic odor, and a warm, pungent taste. These properties it owes to a volatile oil, which was formerly employed, but has been superseded altogether by the oil of thyme, which is called in commerce oil of *origanum*. (See *Oleum Thymi*.)

Two kinds of *origanum* oil are now known commercially: the Trieste oil, of dark color and high specific gravity, and the Smyrna oil, of lighter color, lower specific gravity, and milder taste. The former contains from 60 to 85 per cent. of *carvacrol*, $C_{10}H_{14}O$, a trace of another phenol, and *cymene*, $C_{10}H_{14}$. The latter contains from 25 to 60 per cent. of *carvacrol* and, in addition, *unalool* and *cymene*. The specific gravity of the Trieste oil ranges from 0.94 to 0.98, while that of the Smyrna oil is from 0.915 to 0.945. (Gilde-meister and Hoffmann, *Aetherische Oele*, pp. 813, 814.)

The French oil of marjoram is said to be distilled from *Olinopodium Nepeta* (L), Kze. (*Calamintha Nepeta*, Link. and Hoffm.) It is colorless, but gradually turns yellow on exposure. It is neutral in reaction, sp. gr. 0.904 at 16° C., and optical rotation $[\alpha]_D = +18^\circ 39'$ in chlo-

roform solution. On fractionating, three constituents were isolated, *levo-pinene*, *calaminthone*, and *pulegone*. *Calaminthone* is a new ketone, $C_{10}H_{16}O$. (See P. J., March, 1903.)

Origanum floribundum, of Algeria, yields largely of a volatile oil containing 25 per cent. of thymol. (P. J., Feb. 1903.)

Orobanche. *Leptamnium virginianum* (L.) Raf. (*Orobanche virginiana*, L., *Epifagus americana*, Nutt., *Epiphegus virginiana*, Bart.) *Beech drops. Cancer Root. Orobanche de Virginie*, Fr. *Krebswurz*, G.—This is a parasitic, fleshy plant, found in Northeastern America, growing upon the roots of the beech tree. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful in obstinate ulcers of a cancerous character, to which it was directly applied. Other species of *Orobanche*, growing in America and Europe, have been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter, nauseous taste. In Europe they are called *broom rape*. The allied plants, *Conopholis americana* (L. f.), Wallr. (*Orobanche americana*, L. f.), and *Thalesia uniflora* (L.), Raf. (*Orobanche uniflora*, L., *Aphyllon uniflorum*, T. and G.), of America, are used for the same purposes as the species above noticed, and, like it, are called *cancer root*.

Oroxyllum. *Oroxyllum indicum*, Vent. (Fam. Bignoniaceæ).—This East India bark is said to be not only a tonic and astringent, useful in *diarrhæa*, but also a powerful sudorific. A yellow crystalline substance, *oroxylin*, has been separated from the bark by Naylor and Chapman (P. J. Sept. 1890), and from the seeds by Hooper (P. J., vol. lxi.). The seeds have been used in veterinary medicine.

Orpiment. *King's Yellow.* As_2S_3 .—A native arsenic trisulphide. It is in masses of a brilliant lemon-yellow color, composed of flexible laminae, and slightly translucent. It exists in various parts of the world, but is obtained for use from Persia and China. (Guibourt.) It is sometimes mixed with realgar, which gives it a reddish or orange hue. A similar sulphide may be made artificially by passing hydrogen sulphide through a solution of arsenic trioxide in hydrochloric acid.

Artificial orpiment is prepared for use by fusing together equal parts of arsenic trioxide and sulphur. (Turner.) In Germany, according to Guibourt, it is prepared by subliming a mixture of these two substances. In this case, however, it retains a large portion of the acid undecomposed, and is therefore highly poisonous. Guibourt found a specimen which he examined to contain 94 per cent. of arsenic trioxide and only 6 per cent. of the trisulphide.

Orpiment is an ingredient of certain depilatories. *Atkinson's depilatory* is said to consist of one part of orpiment and six parts of quicklime, with some flour and a yellow coloring matter. (Ann. Ch. Ph., xxxiii. 348.) But this arsenical sulphide is chiefly used in fireworks and as a pigment.

Orris Root. *Iris Florentina*, L. U. S. Secondary List, 1870. *Rhizoma Iridis*, P. G. *Radiæ Iridis Florentinæ*, *Radiæ Ireos*. *Iris de Florence*, Fr. *Florentinische Violeuwurzel*, *Veilchenwurzel*, G. *Ireos*, It. *Lirio Fiorentino*, Sp.—The root (rhizome) of the Florentine *Iris* is perennial, horizontal, fleshy, fibrous, and covered with a brown epidermis. This plant is a native of

Italy and other parts of the south of Europe, where it is also cultivated. The root is dug in spring, and prepared for the market by the removal of its cuticle and fibres. It is cultivated for commerce chiefly in the neighborhood of Florence, and is exported from Leghorn in large casks.

Florentine orris is in pieces of various form and size, often branched, usually about as thick as the thumb, knotty, flattened, white, heavy, of a rough though not fibrous fracture, an agreeable odor resembling that of the violet, and a bitterish acrid taste. The acrimony is greater in the recent than in the dried root, but the peculiar odor is more decidedly developed in the latter. The pieces are brittle and easily powdered, and the powder is of a dirty white color. Vogel obtained from Florentine orris, gum, a brown extractive, fecula, a bitter and acrid fixed oil or soft resin, a volatile crystallizable oil, and vegetable fibre. According to Landerer, the acrid principle is volatile, separating in the form of a stearopten from water distilled from the root. (*A. Pharm.*, lxx. 302.) The solid oil which is prepared in Europe from orris root by distillation has been examined by Flückiger. By repeated crystallization from alcohol and treatment with animal charcoal, inodorous crystals were obtained, having the composition $C_{14}H_{22}O_2$ and the properties of myristic acid, while the odorous principle remained in the mother liquor, so that oil of orris must be regarded as myristic acid impregnated with volatile oil. The acid does not pre-exist in orris root, and is probably liberated from a fat by the influence of steam. (*A. J. P.*, 1876, 411, also 1885, 133.) According to Hager, the commercial oil has the following properties. At the ordinary temperature it is a pea-yellow acid, resembling basilicon ointment (*P. G.*) in color and consistence. It is lighter than water, fuses at from 38° to 40° C. (100.4° – 104° F.) to a transparent liquid, and commences to congeal at about 28° C. (82.4° F.). Two drops of the fused oil dissolve in ten or twelve drops of warm stronger alcohol, and the solution does not separate at a medium temperature. Three drops of the oil and from twenty to twenty-five drops of concentrated sulphuric acid carefully heated to 30° C. (86° F.) yield a clear red-brown liquid, which, after ten minutes, dissolves in 7 Cc. of 90 per cent. alcohol, with a light violet color, gradually becoming darker. Two drops of a solution of the oil in petroleum benzin evaporated spontaneously leave a residue which, with a magnifying power of from fifty to one hundred diameters, has a radiating appearance after a few hours, and shows distinct crystals after a day. One part of orris oil yields, with from three thousand to four thousand parts of weaker alcohol, a solution of which a few drops put upon a handkerchief develop a persistent odor of violets. (*A. J. P.*, 1877, 302.) In order to preserve the root from the attacks of insects, it is recommended to put a little chloroform in the bottle in which it may be kept. (*A. J. P.*, 1858, 310.) The odoriferous principle of orris root was found by Tiemann to be *irone*, $C_{13}H_{20}O$. In endeavoring to effect its synthesis Tiemann was led to the discovery of an isomeric body, *pseudoionone*, by the condensation of acetone and citral. While pseudoionone does not possess the violet odor it can be changed into *ionone*, which has the true violet odor and is now largely manufactured for the perfumery trade in making toilet waters and handkerchief extracts.

Orris root is cathartic, and in large doses emetic, and was formerly employed to a considerable extent on the continent of Europe. It is said also to be diuretic, and to have proved useful in *dropsies*. At present it is valued chiefly for its agreeable odor. It is occasionally chewed to conceal an offensive breath, and enters into the composition of tooth powders. In the form of small round balls, about the size of a pea, it is used by the French for maintaining the discharge from issues, a purpose to which it is adapted by its odor, by the slight acrimony which it retains in its dried state, and by the property of swelling very much by the absorption of moisture.

Orthin. $C_6H_3 \begin{Bmatrix} OH \\ COOH \\ HN.NH_2 \end{Bmatrix}$. Orthohydrazin-para-

oxybenzoic acid is very unstable, but unites with hydrochloric acid, forming orthin hydrochloride, which is stable. This substance was proposed by Kobert (*D. M. W.*, 1890) as an antipyretic; but in the experiments conducted by Unverricht, which have been confirmed by Kaufmann, it was found to have comparatively feeble antipyretic action, and to produce in a great many cases sweating and collapse.

Orthoamidosalicylic Acid. *Acidum orthoamidosalicylicum*. $C_6H_3(NH_2)(OH)COOH$.—This is a grayish, amorphous, almost odorless, slightly sweetish powder, insoluble in water, alcohol, and ether, which has been used by R. Neisser (*In. Dis.*, Bern, 1892) in subacute rheumatism, with alleged good results.

Orthoform. *Methyl paramido-metaoxybenzoate*. $C_6H_3 \begin{Bmatrix} COOCH_3 \\ NH_2 \\ OH \end{Bmatrix}$ (1) (4). This compound forms a white,

odorless and tasteless powder, difficultly soluble in water, easily soluble in alcohol, melting at 118° to 120° C. (244.4° – 248° F.). Orthoform was introduced into practical medicine by Einhorn and Heinz (*M. M. W.*, 1897). Its chloride is very soluble in water, but is so acid in its reactions as to interfere with its use.

The physiological action of orthoform is only so far made out as to show that, probably on account of its insolubility, it has very little influence upon the system whether given by the stomach or hypodermically, Heinz having found that ninety grains produce no distinct symptoms in the lower animals, and seven hundred grains have been applied to a facial ulcer in a week without injurious effect (*L. L.*, 1897); also, according to Neumayer (*M. M. W.*, xlv. 1897), sixty grains taken by a man in the course of a day produced no symptoms whatever, not even evidences of gastro-intestinal irritation.

Locally orthoform has been believed to be actively antiseptic, but Lichtwitz and Sabrazes (*B. M.*, xi. 1897) found that bouillon saturated with it was still capable of serving as a culture medium. The antiseptic influence of orthoform is probably due to its decomposition by ulcerated surfaces. Brought in contact with sound skin or mucous membrane orthoform has no perceptible anæsthetic influence, but in any variety of ulceration, abscess, etc., where it would be brought in contact with the exposed sensitive nerve endings, its influence is decided and prolonged on account of its slow solution and consequent non-absorption for many hours. Externally, orthoform may be used either as a dusting powder, ointment or solution.

According to Yonge (*B. M. J.*, i. 1898), for many purposes the saturated solution of orthoform in collodion is most effective. In diseases of the larynx the parts may be sprayed with a solution of five grains of orthoform and fifty minims each of alcohol and water, which soon coats the diseased surface. In *keratitis* with ulceration, Boisseau commends an ointment made with one drachm each of lard and lanolin and twenty-four grains of orthoform. In many cases orthoform may also be added with advantage, on account of its anæsthetic properties, to ointments containing medicinal substances. According to Neunayer, its local analgesic action is not accompanied by abolition of the sense of touch.

Internally, orthoform in doses of eight grains (0.5 Gm.) has been used with asserted good results in *cancerous* and other ulcerations of the stomach and has been found useful in the treatment of *gastralgia*. Gustav Spiess found that insufflations into the posterior part of the pharynx may greatly alleviate the paroxysms of *whooping cough*.

Occasionally orthoform produces marked irritation and even violent inflammation at the seat of its application, and several cases have been reported in which it has produced sloughing, which has been compared to that caused by pure phenol. According to the majority of clinical reports, orthoform is of very little value except as a local remedy, though relief has been claimed from it in the treatment of *syphilitic headaches*. In the treatment of *sciatica*, *locomotor ataxia*, and other nervous affections, it seems to be of very little use. Doses of five to ten grains (0.32–0.65 Gm.) may be given three to four times a day.

Orthoform, New.—*Methyl metanido-paroxybenzoate* is isomeric with orthoform and possesses the same properties. It forms colorless crystals melting at 142° C. (287.6° F.), or a white powder, slightly agglutinating. It has been used by F. Klaussner in *fissures, wounds, burns, etc.*, with alleged great advantage. (*M. M. W.*, xlv.)

Orthosphon. *Orthosphon stamineus*, Benth. *Java Tea*. (*Fam. Labiata*).—This drug occurs in commerce in the form of small, oval, finely toothed, green leaves, rolled up like tea. Van Itallie has discovered in it a volatile oil and a crystalline glucoside, *orthosphonin*. (*Ph. Ztg.*, Sept. 1886; see also *Répertoire de Pharm.*, 1887, 191.) It is said to be a powerful diuretic, and is highly recommended in *nephritic colic, gravel, uric acid diathesis*, and even *ascites*. The dose is from fifteen to fifty grains (1.0–3.2 Gm.) a day.

Osha Root.—This is the root of *Ligusticum flicinum*, Wats. (*Fam. Umbellifera*), indigenous in Utah and neighboring States and known as *Colorado cough root*. H. Haupt found in it an acid, *oshaic acid*, closely resembling angelic acid (*A. J. P.*, 1867, 1868, 1873.)

Osmic Acid. *Osmium tetroxide*, OsO₄.—A volatile, very odorous, crystalline compound, produced by the action of nitrohydrochloric acid on osmium or either of its lower oxides. Its vapor is very pungent and poisonous, attacking the eyes and respiratory organs. Claus recommends as an antidote to its action cautious inhalation of hydrogen sulphide. Osmic acid melts to a colorless liquid at 90° C. (194° F.), softening at a temperature of 35° C. (95° F.). It is slowly soluble in water; soluble in alcohol and ether; but these solutions are unstable, depositing black *osmium hydride*, Os(OH)₄. *Potassium*

osmate, K₂OsO₄ + 2H₂O, is made by adding potassium hydroxide to an alcoholic solution of osmium tetroxide, and separating the crystals by careful evaporation. In the form of deep, garnet-red crystals, readily soluble in water, but decomposing when in solution or moist air; permanent in dry air. Usually used by injection, hypodermically, in the form of a 1 per cent. solution. The potassium salt is preferred by many to osmic acid for administration. Osmic acid on account of its action upon tissues, is largely used in the making of microscopic preparations. We have no definite knowledge as to its influence upon the animal system when given in small doses. It has, however, been used with alleged success in *sciatica* and also in rheumatic affections both as osmic acid and in the form of *potassium osmate*. By Wildermuth it was used in *epilepsy* in doses of one-sixty-fourth of a grain (0.001 Gm.), repeated until the daily dose amounted to one-quarter of a grain (0.016 Gm.). Stekoulis affirms great success from the injection of fifteen drops (0.75 Cc.) of a 1 per cent. solution deep into the gluteal region close to the sciatic nerve in obstinate *sciatica*. At first the injections are repeated daily, afterwards every three or four days, care being exercised never to insert the needle into the same point twice, and to practise injection along the course of the nerve. Severe but very temporary pain is produced. (*L. L.*, Aug. 13, 1887.) Schapiro confirms the value of the remedy. He injects five drops (0.26 Cc.) of a solution made by the following formula: Osmic Acid 1 part, Glycerin 40 parts, Distilled Water 60 parts. Auerbach has used parenchymatous injections with alleged success for the destruction of morbid growths. (*Journ. of Laryngology and Rhinology*, June, 1891.)

Oxalic Acid. *Acidum Oxalicum*. *Acide oxalique ou carbonéux*, Fr. *Oxalsäure*, Kleesäure, G. H₂C₂O₄·2H₂O = 125.1.—“In small, colorless, prismatic crystals, odorless and of a very sour taste, slightly efflorescent in dry air, fusible at 98° C. (208° F.), and entirely volatile at a red heat.”¹

This acid is found both in animals and vegetables. It is generated occasionally in disease, and it may be deposited in the bladder as calcium oxalate, forming the *mulberry calculus*. In vegetables, it occurs in a free state in the bristles of the chick pea (*Cicer arietinum*, L., *Fam. Leguminosæ*), as an acid potassium oxalate in *Rumex Acetosa*, L. (*Fam. Polygonacæ*),² or common sorrel, in *Oxalis Acetosella*, L. (*Fam. Oxalidacæ*), or wood sorrel, in *Chenopodium Quinoa*, Willd. (*Fam. Chenopodiaceæ*), *Amaranthus caudatus*, L. (*Fam. Amaranthaceæ*), *Mesembryanthemum crystallinum*, L. (*Fam. Aizoidacæ*), and in many other plants. It is said to be formed in the leaves. (*J. Chem. S.*, 1886.) United with lime as raphides, it is abundant in almost every portion of the vegetable kingdom.

Preparation.—According to W. Zopf, a certain *Saccharomyces* (*S. Hausenii*) has the property of producing a fermentation which forms oxalic acid out of sugar; but in the practical arts the sugar is decomposed by nitric acid. Four parts of sugar are acted upon by twenty-four of nitric acid of the sp. gr. 1.24, and the mixture is heated so long as any nitrogen tetroxide is disengaged. A part of the carbon of the sugar is converted

¹ See test-solution of oxalic acid in PART III.

² For fatal poisoning by *Rumex Acetosa*, see *Hospital Gazette*, June, 1886.

into carbon dioxide by oxygen derived from the nitric acid, when thereby is reduced to nitrogen tetroxide. The undecomposed nitric acid, reacting with the remaining elements of the sugar, generates oxalic and saccharic acids, the former of which crystallizes as the materials cool, while the latter remains in solution. The crystals being removed, a fresh crop may be obtained by further evaporation. The thick mother water which now remains is a mixture of saccharic, nitric, and oxalic acids, and, by treating it with six times its weight of nitric acid, the greater part of the saccharic will be converted into oxalic acid. The new crop of crystals, however, will have a yellow color, and contain a portion of nitric acid, the greater part of which may be driven off by allowing them to effloresce in a warm place. It is probable that, in the reaction occurring between nitric acid and sugar, half the carbon of the latter is converted into carbon dioxide, and the other half into oxalic acid. This process has, however, been replaced in practice by the "sawdust process."

Many substances, besides sugar, yield oxalic acid by the action of nitric acid, as molasses, rice, potato starch, gum, wool, hair, silk, and many vegetable acids. In every case in which it is thus generated, the proportional excess of oxygen which it contains, compared with every other organic compound, is furnished by the nitric acid. When the acid is obtained from potato starch, this is first converted into starch sugar by the action of sulphuric acid. For details of this process, see 15th edition *U. S. D.*, p. 90. The yield of oxalic acid from a given quantity of material has been much understated. If properly treated with nitric acid, 100 lbs. of good sugar will yield from 125 to 130 lbs. of oxalic acid, and the same weight of molasses from 105 to 110 lbs.

Certain organic substances yield oxalic acid when heated with potassium hydroxide. Wood shavings, if mixed with a solution of potassium hydroxide and exposed to a heat considerably higher than 100° C. (212° F.), will be decomposed, and partly converted into oxalic acid, which then combines with the alkali. At present most of the oxalic acid of commerce is obtained by heating sawdust with a mixture of sodium hydroxide and potassium hydroxide. Sodium hydroxide alone will not generate the acid, and potassium hydroxide is too costly to be used by itself for the purpose; but Dale ascertained that, by mixing the two in the proportion of two molecules of sodium hydroxide to one of potassium hydroxide, the same or an even better result was obtained than from the latter alone. The mixture of caustic alkalies and sawdust is made into a thick paste and then heated for several hours to a temperature which is gradually brought to 240° C. (464° F.). The gray mass is then washed with sodium carbonate, whereby the potassium is removed as carbonate, the less soluble sodium oxalate remaining. This is converted into calcium oxalate by milk of lime, and the calcium salt then decomposed with sulphuric acid. The impure oxalic acid is then purified by recrystallization. Böhlig has suggested an improvement by precipitating the solution of potassium oxalate with magnesium chloride or sulphate. (Bayer, *N. R.*, Aug. 1877.) As the oxalic acid of commerce often contains foreign matter, it requires for certain purposes to be purified. It has sometimes been fraudulently mixed with 25 per cent. of Epsom salt. E. J. Maumené gives the following process for purifica-

tion, which he says answers better than the method generally recommended. Sufficient hot water is added to the crystals to leave, on the cooling of the solution, from 10 to 20 per cent. undissolved, according to the degree of impurity. The first crystals are put aside. The mother water is then concentrated, and, if the resulting crystals be submitted to two or three successive crystallizations, the acid will finally be obtained free from alkaline oxalate. (*J. P. C.*, 1864, 154.) Stolba prefers the method of purification by crystallization from hydrochloric acid (boiling hot). (*Journ. App. Chem.*, Aug. 1874.) Villiers (*J. Chem. S.*, 1880, 544) prepares anhydrous oxalic acid by dissolving one part of ordinary acid in about twelve parts of warm concentrated sulphuric acid, allowing the oxalic acid to crystallize out.

Properties.—Oxalic acid is a colorless crystallized solid, possessing considerable volatility, and a strong, sour taste. Its crystals have the shape of slender, flattened, four- or six-sided prisms, with two-sided summits, and, when exposed to a very dry atmosphere, undergo a slight efflorescence. It is soluble in 4.5 parts of absolute alcohol, in 7 parts of alcohol, and almost insoluble in ether, chloroform, benzene, and petroleum benzin. The crystals should dissolve in not less than from eight to ten parts of water at 15° C. (59° F.) (greater solubility indicating contamination with adherent nitric acid).

It fuses in its water of hydration at 98° C. (208.4° F.), although continued exposure to a heat of from 60° C. (140° F.) to 70° C. (158° F.) will render it perfectly anhydrous. Solutions of oxalic acid at 100° C. (212° F.) lose acid by sublimation, and at 157° C. (314.6° F.) the anhydrous acid itself sublimates rapidly. If the heat rise to 160° C. (320° F.), much loss of acid occurs. (Allen, *Com. Org. Anal.*, 1879, 233.)

It combines with salifiable bases, and forms salts called oxalates. The most interesting of these are the three *potassium oxalates*, severally called *oxalate*, *binoxalate*, and *quadoxalate* (acid potassium oxalate plus free oxalic acid), and the *calcium oxalate*. The potassium binoxalate and quadoxalate, both popularly called *salt of sorrel* or *essential salt of lemons*, are employed for removing iron mould from linen, and act by their excess of acid, which forms a soluble salt with the ferric oxide constituting the stain. Salt of sorrel is also used extensively in the bleaching of straw goods and other vegetable fibres. Oxalic acid is used for removing ink stains and iron mould, for cleaning the leather of boot tops, and for discharging colors in calico printing. Prussian blue dissolves in aqueous oxalic acid to a clear blue liquid which is often employed as a *blue ink*.

This acid has a very strong affinity for lime, and makes with it an insoluble precipitate consisting of *calcium oxalate*, whenever the acid and the earth are brought into contact in solution. An aqueous solution forms with solution of lime a white precipitate, insoluble in an excess of oxalic or acetic acid, but dissolved by diluted hydrochloric acid. It is even capable of decomposing calcium fluoride, evolving hydrofluoric acid. (*J. W. Slater.*) Oxalic acid and its soluble combinations are the best tests for lime, and, conversely, a soluble salt of lime for oxalic acid. In weak solution the acid is said to absorb oxygen and to be converted into carbonic acid; but a strong solution is quite permanent. (*A. J. P.*, 1870, 317.) When lime is searched for, ammonium

oxalate is the most convenient test. So strong is the mutual attraction between this acid and lime, that the former takes the latter even from sulphuric acid. Hence the addition of a soluble oxalate disturbs the transparency of a solution of calcium sulphate.

Oxalic acid is distinguished from all other common acids by the form of its crystals, and by its solution yielding a precipitate with lime water, insoluble in an excess of the acid or of acetic acid.

Composition.—Anhydrous oxalic acid consists of two atoms of carbon, two of hydrogen, and four of oxygen. It is a dibasic acid. When crystallized, two molecules of water must be added, making the molecular weight of the crystals 125.1. These two molecules of water may be driven off by a regulated heat, by which the acid is made to effloresce. As oxalic acid is the final oxidation product of the diatomic alcohol glycol,

to which the formula CH_2OH is given, we may CH_2OH

conclude that its structural formula is $\begin{matrix} \text{CO.OH} \\ | \\ \text{CO.OH} \end{matrix}$

which explains the readiness with which sulphuric acid splits it up into carbon dioxide, CO_2 , and carbon monoxide, CO, by withdrawing H_2O from its formula, and with which oxidizing agents like manganese and lead dioxide change it into carbonic acid. Anhydrous oxalic acid may be obtained by dissolving the ordinary crystals in ten times their weight of sulphuric acid or concentrated nitric acid and cooling the solution.

Uses and Toxicology.—Oxalic acid has been strongly recommended by F. Poulet and by A. W. Marsh (*T. G.*, 1891) in *amenorrhœa*. Marsh has also found it extraordinarily serviceable in *cystitis*. It is a very active germicide, and, according to Howard A. Kelly, its solution is almost the only practical substance for the perfect disinfection of the surgeon's hands. *Dose*, half a grain (0.032 Gm.) from three to five times a day.

Attention was first called to it as a poison by Royston in 1814, and the certainty and rapidity of its action have caused it to be largely used for suicidal purposes. Death has been produced by it in ten minutes. (*Case, Chem. News*, April 24, 1868.) The minimum fatal dose recorded is one drachm (3.9 Gm.). From the general resemblance which the crystallized oxalic acid bears to Epsom salt, many fatal mistakes have occurred in consequence of its being sold for that saline purgative. It is, however, at once distinguished by its sour taste.

Oxalic acid acts on the economy in two principal ways, according as its solution is concentrated or dilute. When concentrated it causes exquisite pain, followed by violent efforts to vomit, then sudden dulness, languor, and great debility, and finally death without a struggle. When dissolved in twenty times its weight of water, it possesses no corrosive and hardly any irritating power, but causes death by acting on the brain, spinal marrow, and heart. It should be noted, however, that the acid, even in weak solution, always exercises a corroding or softening power on the animal tissues.

The morbid appearances caused by oxalic acid are various. In a dissection reported by Christison, the mucous coat of the throat and gullet had an appearance as if scalded, and that of the gullet could be easily scraped off. The inner coat of the stomach was pultaceous, in many

points black, in others red, and that of the intestines similarly but less violently affected. In another case the whole villous coat of the stomach was either softened or removed, as well as the inner membrane of the œsophagus, so that the muscular coat was exposed, and this coat exhibited a dark, gangrenous appearance, being much thickened and highly injected. The stomach usually contains a dark fluid, resembling coffee grounds, consisting chiefly of altered blood. The tongue and mouth are sometimes white or spotted with white. In a few cases no morbid appearances have been discovered.

In 1879 Kobert and Kürsner announced that in animals oxalic acid may produce glycosuria; this has since been confirmed, and Sarganeck has noted the symptom in human poisoning, so that it is probably a constant phenomenon.

In the treatment of poisoning by oxalic acid, the remedial measures must be employed with great promptitude. Vomiting may be encouraged and the stomach tube used, but unless the antidote be at hand death will rarely be averted. The proper antidote is chalk or magnesia, mixed with water, and as soon as either can be procured, it must be administered in large and repeated doses. In many cases whitewash or some other preparation of lime can be obtained sooner than chalk, and should be at once administered; tooth powder can usually be obtained quickly, and generally (not always) consists chiefly of calcium carbonate. These substances act by forming with the poison an insoluble, inert calcium or magnesium oxalate. The soluble salts of oxalic acid, as ammonium oxalate and potassium oxalate, are equally poisonous, and the antidotes for them are lime water or solutions of magnesium salts.

Oxalis. *O. Acetosella*, L. *Wood Sorrel*. *Acetosella*. *Alléluia*, *Surelle*, *Pain de Coucou*, Fr. *Sauerklee*, *Hasenklee*, G.—The wood sorrel is a small, stemless plant of the fam. *Oxalidaceæ*. It is a native both of Europe and North America. Other indigenous species of oxalis possess similar properties to *O. Acetosella*. The whole herbaceous portion may be used.

Wood sorrel is without odor, and has an agreeable sour taste. It owes its acidity to *acid potassium oxalate* or *potassium binoxalate* (HKC_2O_4). The same salt may be prepared by exactly neutralizing one part of oxalic acid in solution, with potassium hydroxide, or potassium carbonate, then adding one part more of the acid, and evaporating the solution so that it may crystallize upon cooling. Acid potassium oxalate is in rhomboidal crystals, of a sour, pungent, bitterish taste, soluble in forty parts of cold and six parts of boiling water (Kane), and unalterable in the air. *Potassium tetroxalate* or *quadraxalate* is often substituted for the binoxalate. It is prepared in the same manner except that, instead of one part, three parts of the acid are added to the original proportion neutralized by potassium hydroxide. Both are poisonous, though in a less degree than uncombined oxalic acid. The fresh plant, eaten raw, is useful in *scurvy*.

Oxalis crassicaulis, Zucc., a Peruvian species, yields edible tubers and, by expression from its leaves, a very sour and astringent juice, which is employed, in the form of syrup, in *hemorrhages*, chronic *catarrh*, and *gonorrhœa*, with asserted advantage.

Oxycamphor. C_8H_{14} $\begin{matrix} \text{CHOH} \\ \diagup \\ \text{CO} \end{matrix}$. This oxidation product of camphor is a white crystalline powder,

melting at from 203° to 205° C. (397.4°–401° F.) and volatile in a current of steam. Soluble to a slight degree in cold water; more soluble in hot water. It is stated that it acts as a stimulant to the cardiac muscle and also to the centric and peripheral vasomotor nervous system, and as a calmative to the respiratory centres. It has been used with asserted good results for the relief of both cardiac and pulmonic *dyspnoea*. *Dose*, from eight to fifteen grains (0.5–1.0 Gm.).

Oxychinaseptol. *Diaphtherin.* $C_6H_4(SO_2)$
 $\{ O-NH.C_6H_5(OH)$
 $\{ O-NH.C_6H_5(OH)$. This substance is made by uniting two molecules of oxychinoline, $C_9H_6N(OH)$, with one molecule of phenol-sulphonic acid, $C_6H_5(HSO_3)OH$. It occurs in yellowish hexagonal crystals, melting at 85° C. (185° F.), very soluble in water and diluted alcohol. Its solution is decomposed by alkalis. According to the researches of Emmerich (*M. M. W.*, 1892), it is much more powerful as an antiseptic than phenol; two-tenths of one per cent. solution is sufficient to kill the comma and diphtheria bacilli in ten minutes, and three-tenths of one per cent. solution destroys the pus organisms in thirty minutes. It is also asserted that it is practically innocuous to higher animals, the subcutaneous injection of five cubic centimeters of a 5 per cent. solution producing no serious effects upon guinea pigs. It has been used in practical surgery, especially by Kronacher, who has employed from $\frac{1}{2}$ to 1 per cent. solution with great satisfaction for the general purposes of the antiseptic treatment of wounds. Such solution produces no irritation except in some cases a momentary burning. Rohrer (*Corresp. f. Schweiz. Aerz.*, Nov. 1892) commends the remedy as a local application in disease of the nasal mucous membrane. The solution does not stain the hands, but forms on steel instruments a black deposit which is readily washed off.

Oxydendrum. *Oxydendrum arboreum* (L.), DC. *Sour Wood. Elk Tree. Sorrel Tree.* (Fam. Ericaceæ.)—The leaves of this indigenous tree are said by eclectic physicians to be a powerful diuretic, useful in *dropsy*. A semi-solid extract may be made, one part representing five of the drug. *Dose*, from five to fifteen grains (0.32–1.0 Gm.). Of the fluidextract the *dose* is from a half to two fluidrachms (1.8–7.5 Cc.).

Oxynaphthoic Acid. *Alpha-naphthol-carboxylic acid*, $C_{10}H_6 \begin{Bmatrix} COOH \\ OH \end{Bmatrix}$. This is the counterpart among the naphthalene derivatives of salicylic acid among the benzene derivatives, and is made in an analogous way by the action of carbon dioxide and sodium upon *α-naphthol*. It forms a white, inodorous, microcrystalline powder fusing at from 185° to 186° C. (365°–366.8° F.), and is soluble in 30,000 parts of cold water, more readily soluble in alcohol, chloroform, benzene, and oils, both fixed and volatile, also in aqueous solutions of ammonium bicarbonate, which form salts. It is antizymotic, disinfectant, and recommended against phylloxera. Its antizymotic action is said to exceed that of salicylic acid as five to one, and a 5 per cent. ointment has been lauded in *soabies*.

Oxypropylenediisoamylamine.—Louise affirms that this colorless liquid, which is soluble in alcohol, ether, and oils and insoluble in water, resembles atropine in its action upon the heart, and that it causes great rise of the arterial pressure and of the temperature of the body. (*L. L.*, 1887.)

Ozokerite.—This substance, which is brought from Galicia, in Austria, and from near the Caspian Sea, as well as mined in Southern Utah, in its crude state is a solid, varying in color from a dirty greenish to nearly black. When purified by treatment with sulphuric acid and alkali and subsequent filtration while melted through bone black or other filtering medium, it is a hard, white, spermaceti-like substance, and is extensively used in England as well as in Austria in the manufacture of candles. (See *Ceresin*.) It is a mixture of natural paraffins. It is said to resemble tar in its therapeutic properties, and, mixed with glycerin or linseed oil, has been employed in *skin diseases* by Purdon as a substitute for that remedy. (*B. F. M. R.*, 1872, 535. See also *A. G. M.*, Avril, 1873, and *Am. Drug.*, 1892, 40.)

Ozone (O_3) is recognized as an active modification of the element oxygen. It is considered to differ from the common form in being more condensed and at the same time more active. It has a peculiar odor, somewhat resembling that of diluted chlorine. Ozone changes gradually at the ordinary temperature into common oxygen, and at 237° C. (458.6° F.) the change is instantaneous. It is one of the most powerful oxidizing agents known, attacking and at once destroying organic substances, such as caoutchouc, paper, cork, etc. It also decolorizes most organic pigments. Ozone is somewhat soluble in water, imparting to water its peculiar odor, as well as its oxidizing power. According to Carius, 1000 volumes of water dissolve 4.5 volumes of ozone, and it is much more soluble in certain ethereal oils. The power of these latter as carriers of oxygen and disinfectants is thus explained. At one time ozone was thought to be peroxide of hydrogen, but Marignac and De la Rive demonstrated its true nature. Hautefeuille and Chappius (*C. R. A. S.*, xciv. 1249) succeeded in producing "liquid ozone" by applying a pressure of 125 atmospheres to richly ozonized oxygen at –100° C. (–148° F.). It is stated to be of a dark indigo color.

Ozone has not been obtained free from oxygen; indeed, it is probable that 1 per cent. of ozone is the highest concentration reached in its production. It is prepared by the decomposition of water by the battery, by the passage of the silent electric discharge through air or oxygen, by the slow oxidation of phosphorus in moist air and in other cases of slow combustion, and, lastly, by the action of sulphuric acid upon barium dioxide and potassium permanganate. Poulsen has suggested the following method of making ozone. The apparatus consists of a wide-necked glass jar, with a double cover of porcelain plates, finely perforated; the upper plate closes in the mouth of the jar, while the lower one is inserted in the neck of the jar, about two inches below the other. Through the centre of each of these covers a glass rod passes, terminating at the lower end (which is curved upward) in a small cup for holding a piece of phosphorus; in the jar is placed a given quantity of acidulated water, its level just above the cap containing the phosphorus, which, when the apparatus is not in action, is always submerged. A little potassium permanganate is added to the acid solution, and to produce ozone the phosphorus is raised, by means of the glass rod, just to the surface of the water. Chemical action produces phosphorous acid in the form of fumes by the contact of the phosphorus with the air, and the fumes are seen

to rise to a certain height, when they are deflected down upon the solution, into which they are absorbed, and converted into phosphoric acid by being oxidized by the potassium permanganate. Meanwhile, ozonified oxygen is produced, and, passing out through the perforations in the covers, is distributed in the atmosphere. The presence of ozone in the air or in gases is indicated by its action on paper moistened with potassium iodide and starch solution. This is turned blue, and if reddened litmus paper is moistened with potassium iodide, this is also blued. Another test is found in the use of paper moistened with an alcoholic solution of guaiacum, which is changed to light blue. Its presence in the air is now fully established, although in thickly inhabited districts it is almost always absent, as it is reduced to ordinary oxygen by the organic emanations constantly sent out into the air. In the air of the country, and especially in sea air, the presence of ozone can often be recognized by its peculiar odor. The probable cause of the formation of ozone in the air has been pointed out by Gorup-Besanez, as he has shown that ozone is invariably formed when water evaporates, and it is to this source, rather than to the electrical discharges, that the production of ozone must be traced.

Pæonia. *Pæonia officinalis*, L. *Peony*. *Pivoine*, Fr. *Gichtrose*, *Pfingstrose*, G. (Fam. Ranunculaceæ).—The root of the garden peony consists of a caudex about as thick as the thumb, which descends several inches into the ground, and sends off in all directions spindle-shaped tubers, which gradually taper into thread-like fibres, by which they hang together. It has a strong, peculiar, disagreeable odor, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acid. The odor is lost, or much diminished, by drying. Peony root was in very great repute among the ancients as a charm and as a medicine in *epilepsy*. In modern times it has been used as an antispasmodic. According to Rochebrune (*Toxicolog. Africaine*, i.), it contains an active alkaloid, *pænone*. The expressed juice is milky, of a strong odor and very disagreeable taste. The seeds are roundish-oval, about as large as a pea, externally smooth, shining, and nearly black, internally whitish, inodorous when dry, and of a mild oleaginous taste. By some authors they are said to be emetic and purgative, by others antispasmodic. The dose of the fresh root or seeds is from two drachms to an ounce (7.7–31.0 Gm.), boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried. Dose, of the expressed juice of the root, one fluidounce (30 Cc.).

W. Will obtained from an aqueous distillate of the root of the Japanese *Pæonia Moutan*, Simson, an aromatic ketone in colorless crystals. (*Ber. d. Chem. Ges.*, xix. 1777.) According to Nagae, this substance has the formula $C_9H_{10}O_3$. (*Ibid.*, xxiv.) It has been prepared by Schimmel & Co., under the name of *peonol*. It has a pleasant aromatic odor, and crystallizes in large needles. No essential oil was found in the root. (*Schim. Rep.*, Oct. 1890.) Dragendorff has found in the seed of *P. peregrina*, Mill., a fixed oil, an alkaloid, and *pæonic acid*. (*Jahresb.*, 1879.)

Palicourea. *Palicourea rigida*, H. B. K. (Fam. Rubiaceæ).—The leaves of this tree are used in Brazil as a diuretic and diaphoretic. In 1866 Peakholdt found in them an alkaloid and three organic acids. One of these acids, consisting of a

yellow, oily liquid with an overpowering odor, was found to be distinctly poisonous, one drop injected into a pigeon being enough to cause death. This was called *myotonic acid*. A crystalline *palicourio acid*, an amorphous tannin, and another amorphous non-toxic bitter principle were also isolated. Santesson has confirmed the presence of an alkaloid. (*A. Pharm.*, 235.)

Palladous Chloride. *Palladii Chloridum*. $PdCl_2$.—This is a blackish-brown mass, soluble in water, which has been recommended as a reagent for determining the malic acid in wine. It has been used to some extent in medicine as a local germicide, and has been recommended in the treatment of *phthisis* in doses of one-fourth to one-third of a grain (0.016–0.021 Gm.) three or four times a day.

Panax. *Panax quinquefolius*, L. *Panax*, U. S. 1870. *Ginseng*, Fr., G., Sp. *Ginseng*, It.—American or false ginseng grows in the hilly regions of the Northern, Middle, and Western States, preferring the shelter of thick, shady woods. The root is the part employed. This is collected in considerable quantities in Ohio and West Virginia, Minnesota, etc. It is also cultivated. (*A. J. P.*, 1891; *Ph. Era*, 1895, 359.) It is not used in America, but is exported to China. While supplied with ginseng exclusively from their own country, which furnished the root only in small quantities, the Chinese entertained the most extravagant notions of its virtues, considering it a remedy for all diseases, and as possessing almost miraculous powers in preserving health, invigorating the system, and prolonging life. It is said to have been worth its weight in gold at Pekin, and the first shipment from North America to Canton yielded enormous profits. John Henry Wilson (*P. J.*, July, 1888) states that there are in the Chinese market five ginsengs, four of them of Asiatic origin, derived from *Panax Ginseng*, Nees, not C. A. Meyer (*Aralia Ginseng*, Decne. and Planch.), the fifth the American ginseng from *Panax quinquefolius*. According to E. M. Holmes, *T'ang-shên*, which is used by the poor of China as a substitute for the costly ginseng, is a root of a new campanulaceous plant, *Codonopsis Tangshen*, and is exported from Hankow and Oo-chang to the extent of five hundred tons annually. (*P. J.*, xxi.) For an account of the Chinese methods of using ginseng, see *P. J.*, vi. 86.

On account of the growing scarcity of the American ginseng plant, experiments have been made by the State of Pennsylvania to determine whether it can be grown profitably, resulting in the conclusion that in five years an acre of ground would yield a profit of fifteen hundred dollars, without allowance for rental, but, according to Jackson (*P. J.*, 70, p. 785), many precautions are necessary for success. The cultivated roots were larger than those of the wild plant. (For details of culture and preparation, see *Bulletin 62, Pennsylvania State Agricultural Experiment Station*; J. U. Lloyd's paper, *Proc. A. Ph. A.*, 1901, p. 90; *Ph. Era*, 1900, p. 581; 1903, p. 497; *P. J.*, 1904, p. 652.)

The root is fleshy, somewhat spindle-shaped, from one to three inches long, about as thick as the little finger, and terminated by several slender fibres. Frequently there are two portions, sometimes three or more, connected at their upper extremity, and bearing a supposed, though very remote, resemblance to the human figure, from which circumstance it is said that the Chinese name *ginseng* originated. For an account of the

ginseng cultivation in Corea, see *P. J.*, 1885, 732; and of its collection in the United States, see *D. C.*, 1884, 33. When dried, the root is yellowish-white and wrinkled externally, and within consists usually of a hard central portion, surrounded by a soft whitish bark. It has a feeble odor, and a sweet, slightly aromatic taste, somewhat analogous to that of licorice root. It has not been accurately analyzed, but is said to be rich in gum and starch, and contains albumen. S. S. Garrigues obtained from it a peculiar substance, which he named *panaquilon*, and gave the formula $C_{12}H_{25}O_9$. To prepare it he heated a cold infusion so as to separate the albumen, filtered, concentrated to a syrupy consistence, precipitated by a concentrated solution of sodium sulphate, washed the precipitate thoroughly with the saline solution, and then treated it with alcohol, which dissolves the principle in question, and yields it on evaporation. To purify it, he dissolved it in water, treated the solution with animal charcoal, again evaporated, and dissolved the residue in absolute alcohol, which is finally distilled off. Panaquilon is an amorphous yellow powder, soluble in water and alcohol, but not in ether, of a sweet bitterish taste, and has the characteristic property that, when treated with strong acids, it is converted into a white substance, insoluble in water, with the escape of carbon dioxide and water. Garrigues proposed for this white substance the name of *panacon*, $C_{11}H_{19}O_4$. (*A. J. P.*, xxvi, 511.) Davydow (*A. J. P.*, 1890, 338) investigated these principles discovered by Garrigues, but adds nothing new to our information concerning them. The root is sometimes submitted, before being dried, to a process of clarification, which renders it translucent and horny, and enhances its value as an article of export. The extraordinary medicinal virtues formerly ascribed to ginseng had no other existence than in the imagination of the Chinese. It is little more than a demulcent, and in this country is not employed as a medicine. Some persons, however, are in the habit of chewing it, having acquired a relish for its taste, and it is sold chiefly to supply the wants of these.

Panbotano Bark.—The root of the Mexican leguminous tree *Calliandra Houstoni*, Benth., has been highly recommended by Valude as an antiperiodic, although Villejean was not able to find in it either an alkaloid or a glucoside. (*Journ. de Sci. Méd. de Lille*, 1890.) Pouchet (*Nouv. Rem.*, 1896), however, states that he has found in panbotano, besides saponin, an alkaloid which produces death by systolic arrest of the heart. Both Dinau (*Thèse de Paris*, 1896) and Crespin confirm its antiperiodic value. (*B. G. T.*, Aug. 1895.) A tincture representing two ounces of the root is taken in four doses during twenty-four hours.

Pancreon is a preparation obtained by the action of tannic acid on pancreatin, containing ten per cent. of the former in combination. It is a grayish, odorless powder which is affirmed to have strong trypsinolytic, amylolytic, and emulsifying properties. It is further claimed to be superior to pancreatin in not losing its activity in the stomach. *Dose*, eight to fifteen grains (0.5–1.0 Gm.).

Pangium. *Pangium edule*, Reinw. (Fam. Samydecæ).—This East Indian tree, which is said to possess anthelmintic and narcotic properties, and to be capable of causing death, according to Blume, contains an alkaloid resembling *menispermine*.

Pao-Pereira Bark.—Under this name a bark is employed in Brazil as a febrifuge. It is supposed to be the product of *Geissospermum lœve*, Miers., or of *G. Vellozii*, Allem. (Fam. Apocynacæ.) O. Hesse has found an alkaloid, *geissospermine*, $C_{19}H_{24}N_2O_2 + H_2O$, in it, (see *P. J.*, viii, 648), but he seems to have been preceded in this discovery by Santos. (*A. J. P.*, 1878, 184.) Peretti has discovered in the root a second alkaloid, *pereirine*, $C_{19}H_{24}N_2O$, which, according to Guimaraes (*B. M. J.*, vol. i, 1887), in sufficient doses causes paralysis with elevation of temperature, ending in death. It has been given to man as an antiperiodic in doses of thirty grains (2.0 Gm.) a day. (See also *A. J. P.*, 1886, 278.) Later a third alkaloid, *vellösine*, $C_{23}H_{28}N_2O_4$, was found. This forms colorless crystals, melting at 189° C. (372.2° F.), insoluble in water, easily soluble in alcohol and ether. In concentrated nitric acid it dissolves with a purplish-red color, which is very stable.

Papaya. *Melon Tree.* *Papaw.*—The *Carica Papaya*, L. (Fam. Papayacæ), is an herbaceous tree, everywhere cultivated in tropical countries for the sake of its fruit. The fruit sometimes attains a size larger than that of a man's head. According to Peckholdt (*P. J.*, Nov. 1879), the milky juice is contained in all parts of the tree, but in such small quantity, save in the unripe fruit, that it is always procured from the latter. One fruit will yield about 33 Gm., which is obtained by scratching through the skin in various places; the process does not interfere with the ripening of the fruit, but it is said that the seeds will not germinate. The milk has an acid reaction, an astringent bitterish taste, and a sp. gr. of 1.023. Upon standing for a few minutes it separates into two parts, an aqueous liquid and a white, somewhat coagulated pulpy mass. In the aqueous portion is an albuminous substance, to which the names of *papain* and *papayotin* have been given. According to the researches of S. H. C. Martin, papaw juice contains papain, which is associated with an albumose, also a milk-curdling ferment. The proteids present in papaw juice were found to be as follows: 1. Globulin, resembling serum globulin in its most important properties. 2. Albumin. 3. β -phytalbumose, precipitated almost completely by heat, by saturation with neutral salts, but not by dialysis. It differs from the heteroalbumose of Kühne and Chittenden by not being precipitated by dialysis, by copper sulphate, or by mercuric chloride. 4. α -phytalbumose, soluble in cold or boiling water; not precipitated by saturation with neutral salts, except in an acid solution. This is the *vegetable peptone* referred to by Vines (*J. P.*, iii.) as *hemialbumose*. It differs from the protoalbumose of Kühne and Chittenden by its non-precipitation by sodium chloride or by copper sulphate. No peptones occur in the juice, but *leucine* and *tyrosine* are present. (*J. Chem. S.*, 1886, 642; see also *P. J.*, 1885, 129.) The milky juice of the papaw can be imagined as quite akin to the gastric or pancreatic juice of the animal organism. In a representative preparation the ferment action seems to be most marked when all the proteids are associated together in the natural form; but the action of this ferment presents features which contrast peculiarly with those of the ordinary digestive ferments. In its action upon albumin the enzyme of the papaw produces products which have a close relation to those produced by tryptic and pepsin digestion. The action of the papaw fer-

ments on milk is quite identical with the action of fermentation. There is first the act of curdling, in which the casein is separated into a soft flocculent precipitate, and this is followed by a digestion of the proteids, during which process they are converted into soluble and diffusible products. The amount of starch-converting ferment is not large, but sufficient in the fresh latex to promptly act upon starch paste, thinning it, and converting a portion at least into soluble starch and dextrin. The import of the rennet ferment and the pectase probably present require further investigation. The statement appears to be warranted that the digestive action of the ferments contained in the papaw latex and the products formed in such are quite identical with that of animal and vegetable ferments in general. Other constituents of the papaw tree—*Carica Papaya*—are a glucoside, *caricin*, and an alkaloid, *carpaine*. The glucoside resembles *sinigrin*, and is obtainable, so far as the author's experience is concerned, only from the seed, in which it is fairly abundant. These seeds also contain the glucoside-splitting ferment, *myrosin*, and by the reaction of the two a volatile pungent body is produced, suggestive of oil of mustard in odor. The alkaloid, *carpaine*, has so far only been obtained from the leaves. Physiologically, this alkaloid has the effect of a heart stimulant, quite similar to that of digitalis. (*A. J. P.*, July and August, 1901, 336-48 and 383-39.) Van Rijn extracted from the leaves of *C. Papaya* an alkaloid, *carpaine*, $C_{14}H_{25}NO_3$, which is used as a febrifuge. Oefele regards this alkaloid as a substitute which may be used for digitalin.

According to Wurtz, the fibrin is dissolved whether the solvent solution be alkaline or acid. Brunton and Wyatt and also Martin affirm, however, that one-half per cent. of hydrochloric acid will prevent digestion, but Albrecht reasserts that hydrochloric acid hastens the action of the ferment, and states that the official preparation in use in the Paris hospitals is an acid one. In order entirely to convert fibrin into pure peptone so that nitric acid will produce no precipitate, the proportion of the ferment should be as great as 3 per cent., and digestion must continue for forty-eight hours at 50°C . (122°F .)

Papaya juice has a tendency to spoil by undergoing a butyric fermentation, but Wurtz found that the addition to it of glycerin preserved it without interfering with its digestive power. Imported in this form, it was a thick, milky liquid. As it now occurs in commerce, papain is a grayish, fine powder, which in appearance, odor, and taste strongly suggests pepsin. Recently it has been much used as an internal medicine in *dyspepsia* and *gastric catarrh*, and as a local application for the destruction of false membranes, *warts*, *tubercles*, walls of old sinuses, and even of *epithelioma*. It is not caustic nor astringent, but destroys the part by virtue of its power of dissolving not only muscular but connective tissue. Jacobi affirms (*T. G.*, vol. ii.) that diphtheritic membranes are dissolved in a few hours by the hourly application of a mixture of one part of papain with two parts each of water and of glycerin. It is stated that from time immemorial the fresh leaves of the papaya plant have been used by the Indians to wrap meat in to make it tender, and as a dressing to *foul wounds*. Peckoldt says that, taken internally, the juice is reputed to cause intestinal inflammation. No recent observers have noted such influence. According to Brunton, the *dose* is from

five to ten grains (0.32–0.65 Gm.). Injected into the venous circulation it acts as a powerful poison, of which a single grain is sufficient to kill a rabbit.

Under the name of *papayotin*, *papain*, or *papoid*, the more or less impure ferment of the *Carica Papaya* is put upon the market, and, according to various authorities, it acts powerfully upon starch, converting it into maltose; emulsifies fat, and converts albuminoids into peptones. It is asserted for it that, when the stomach is acid, it is much superior to pancreatin, because its action is not markedly affected by contact with the acid. In experiments made by H. C. Wood with a papoid from one of the most renowned manufacturers no digestion occurred, and it is probable that much of the article of commerce is inert.

Paraform. *Paraformaldehyde*. *Triformol*. *Trioxymethylene*.—This compound, which may be considered as a polymerized formaldehyde, is a colorless, crystalline powder, melting at 171°C . (339.8°F .), which even at ordinary temperature, but more rapidly on heating, evolves vapors of formaldehyde. It is soluble in water, but scarcely soluble in alcohol and ether. It is used as an internal antiseptic in *doses* of from eight to fifteen grains (0.5–1.0 Gm.) and externally in surgery as an antiseptic, and in the form of tablets to liberate formaldehyde gas by heating in "formaldehyde lamps."

Parameria. *Parameria vulneraria*, Radlkofer. (Fam. Apocynaceae.)—This tree yields the *Balsam de Taguloway* of the Malays. (See *A. Pharm.*, Nov, 1885.)

Paramidoacetophenone. $C_6H_4NH_2.CO.CH_3$. This substance occurs in crystals soluble in boiling water, alcohol, and ether, and melting at 106°C . (222.8°F .). It has been used in the practical application of Ehrlich's *dialzo test*. Two solutions are used for this purpose, as follows:

Solution 1.—Paramidoacetophenone, 0.5 Gm.; hydrochloric acid, 50 Gm.; water, 1000 Gm. Solution 2.—Sodium nitrite, 0.5 Gm.; distilled water, 100 Gm. Both solutions must be kept in dark bottles, and when required for use 2 Cc. of Solution 2 should be added to 100 Cc. of Solution 1. In testing, fill one-fourth of the test glass with the urine, add an equal quantity of the diazo reagent and mix both fluids; then add at one pouring a quantity of ammonia equal to about one-seventh or one-eighth of their combined bulk and shake vigorously. The reaction is regarded as positive if the fluid acquires a distinctly red color, while the foam produced by shaking should be wine-colored.

Parietaria. *Parietaria officinalis*, L. *Wall Pelitory*. *Pariétaire*, *Perce-muraille*, Fr. *Glaskraut*, G. (Fam. Urticaceae.)—A perennial European herb, growing on old walls and heaps of rubbish. It is diuretic and refrigerant, and was formerly used in urinary complaints and *dropsy*, in the form of decoction or of the expressed juice.

Paris Green. *Schweinfurt Green*. *Aceto-Arsenite of Copper*. $Cu(C_2H_3O_2)_2.3Cu(AsO_2)_2$. This substance, which was originally made for a pigment, is now used to an enormous extent for dusting on potato vines to destroy the so-called *potato bug*, or *Colorado beetle*, *Doryphora decemlineata*. It is made by mixing five parts of verdigris with sufficient water to form a thin paste, and adding to this a boiling solution of four parts of arsenic trioxide in fifty parts of water, keeping the mixture at the boiling temperature, and adding a little acetic acid to cause it to retain a

brilliant color. It is rarely found pure in commerce. Numerous cases of poisoning have occurred through carelessness in its use as an insecticide. The treatment would be the same as that for poisoning by arsenic. *Lead arsenate* (*Chem. News*, 1896, 17) has been used as a substitute for Paris green as an insecticide.

Parkia. *Parkia biglandulosa*, W. and A. (*P. africana*, R. Br.). *African Locust*. *Nitta* or *Nutta tree*. Doura. Houllé. *Neretou*.—This is an African leguminous tree, from the dried seeds of which a farinaceous food is prepared by the natives. According to De Rochebrune (*Toxicolog. Africaine*, 1898), it contains a peculiar crystalline alkaloid, *parkine*, which resembles in its physiological activity physostigmine.

Parthenium. *Chrysanthemum Parthenium* (L.), Pers. (*Matricaria Parthenium*, L., *Pyrethrum Parthenium*, Sm.) *Feverfew*. *Matricaire*, Fr. *Mutterkraut*, G. (Fam. Compositæ.) A perennial herbaceous plant, about two feet high, with an erect, branching stem, pinnate leaves, oblong, obtuse, gashed, and dentate leaflets, and compound flowers in a corymb upon branching peduncles. It is a native of Europe, but cultivated in our gardens. The whole herbaceous part is used. The plant has an odor and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers and in its medicinal virtues. According to Zeller, a pound of it yields 4.8 grains of volatile oil. (*Centralblatt*, 1855, 205.) The volatile oil is greenish, boils between 165° C. (329° F.) and 220° C. (428° F.), and separates on standing *pyrethrum camphor*, $C_{10}H_{16}O$, containing in addition a hydrocarbon and an oxidized oil. (Desaignes and Chautard, *J. P. C.* (3), 13, 241.) Though little employed, it is undoubtedly possessed of useful tonic properties. The flowers of this and of a closely resembling species, *Matricaria parthenoides*, Desf., are said to be used in France, to a considerable extent, indiscriminately with those of the true chamomile plant, *Anthemis nobilis*, which they closely resemble, especially when double. They may, however, be distinguished, in this state, by their peculiar odor, their smaller receptacle, which is, moreover, rounded and flattened above, instead of being conical and somewhat pointed as in the *Anthemis*, and by the tubular five-toothed central florets, which in the chamomile are small, few, and scarcely visible, but in the two former species are large, very numerous, and very long.

Parthenium hysterophorus, L.—José Torar has found *parthenine* and four other alkaloids besides *parthenic acid*, in this Cuban plant which is used by the natives as a febrifuge and antiperiodic. Of the alkaloids, *parthenine* is crystallizable and is apparently the active principle. It has been extracted and studied again by H. Vin Army (*A. J. P.*, 1890, 121), who believes it to be a bitter glucoside and not an alkaloid. In doses of three grains (0.2 Gm.) it is said to quicken the heart, and in doses of fifteen grains (1.0 Gm.) to slow cardiac action, while fifty grains (3.2 Gm.) not only lessen the arterial pressure and respiratory frequency but reduce the bodily temperature. In doses of from seven to ten grains (0.45–0.65 Gm.) it is affirmed to be useful in neuralgia. (See D. M. W., Feb. 1886; *Journ. de Méd. de Paris*, March, 1887; *J. P. C.*, xii, 1885; *A. J. P.*, 1897, 169.)

Parthenium integrifolium, L., *American Feverfew*, *Wild Quinine* (Fam. Compositæ), is an

herbaceous perennial, growing abundantly in the prairies of the Southwestern States, which has been used as a tonic and antiperiodic; two ounces (62 Gm.) of the flowering tops may be given in infusion.

Passiflora. *Passiflora incarnata*, L. (Fam. Passifloraceæ.)—The indigenous *American Passion Flower* has been used in doses of from ten to thirty minims (0.6–1.8 Cc.) of a saturated tincture, in neuralgias, sleeplessness, dysmenorrhœa, as well as in diarrhœa and dysentery. I. Ott (*Medical Bulletin*, Dec. 1898) finds that it is a depressant to the motor side of the spinal cord, but increases the rate of the respiration, and that it has very little effect upon the circulation, only temporarily reducing the arterial pressure.

Patent Yellow. *Mineral Yellow*.—A pigment, consisting of lead chloride combined with lead monoxide. It is prepared by mixing common salt and litharge with a sufficient quantity of water, allowing the mixture to stand for some time, then washing out the liberated soda, and exposing the white residue to heat.

Paulowilhelmia. *Paulowilhelmia speciosa*, Hochst.—This acanthaceous plant is used by the Aquapine tribe on the Gold Coast, as a fish poison, under the name of *adubiri*. (*P. J.*, xx, 1890.)

Peach Leaves. *Leaves of Amygdalus Persica*, L. *Persica vulgaris*, Miller. *Prunus Persica*, Stokes. *Pêcher*, Fr. *Pfirsich*, G.—The peach tree is supposed to have been originally brought from Persia, but flourishes everywhere in the warm temperate zone. Peaches are among the most grateful and wholesome of our summer fruits. They abound in saccharine matter, which renders their juices susceptible of the vinous fermentation, and a distilled liquor prepared from them has been much used, in some parts of the country, under the name of *peach brandy*. The kernels of the fruit resemble, physically and chemically, bitter almonds, for which they are frequently, and without inconvenience, substituted in our shops. The flowers, leaves, and bark also have the peculiar odor and taste of bitter almonds, and yield hydrocyanic acid. The leaves afford a volatile oil by distillation. The distilled water prepared from them was found in one instance to contain 1.407 parts of hydrocyanic acid in 1000, and in another only 0.437 parts in the same quantity. From some experiments it is inferred that the proportion of acid is greatest where there is least fruit. (*A. J. P.*, xxiv, 72.)

Peach kernel oil made by expression has found its way into Western Europe from the Levant, and is used in Italy and Southern France largely as an adulterant of almond oil. It is described as of a light yellow color, having the taste and odor of almond oil. It thickens at –9° C. or –10° C. (15.8° F. or 14° F.), and solidifies at –18° C. (–0.4° F.). The sp. gr. at 15° C. (59° F.) is 0.915. It gives with strong nitric acid a dark brown color, with sulphuric acid a dark brown becoming lighter, with solution of zinc chloride a purplish brown; forming with the elaidin test in two hours a mass of butter-like color and consistency. *Peach kernel oil* has a saponification value of 189–192 and an iodine figure of 93.5.

The leaves of the peach are said to be laxative, and, owing to the hydrocyanic acid which they yield, almost all parts of the tree have a sedative influence over the nervous system, and have been used with asserted advantage in *whooping cough*, *irritability of the bladder*, etc. The dried leaves may be employed (an ounce to a pint of hot

water) in infusion, but the tincture of the inner bark (an ounce to a pint of diluted alcohol), *dose*, from ten to thirty minims (0.6–1.8 Cc.) is possibly preferable. The flowers of the peach are affirmed to be laxative and vermifugal, in half-fluid-ounce (15 Cc.) doses when fresh, given in the form of syrup. Cases of fatal poisoning in children from their use are on record. The peach kernels are distinctly active, and when rubbed up with cold water form an emulsion which may be used in place of cherry-laurel water or other preparations of hydrocyanic acid.

Pearl White. *Pearl Powder*.—Bismuth oxychloride prepared for cosmetic use.

Peganum. *Peganum Harmala*, L. (Fam. Rutaceæ.)—In the seeds of this plant Goebel (1837) found the alkaloid *harmaline*, and Fritzsche (1847) a second alkaloid, *harmine*, which have been re-studied by Fischer and Täuber. (*A. J. P.*, 1886, 89.)

Pelargonium. *Pelargonium odoratissimum*, Soland. *Rose Geranium*. (Fam. Geraniaceæ.) This well-known plant, which is a favorite for its odor in our dwellings and conservatories, is a native of Cape Colony, South Africa, but is said to be cultivated extensively in the south of France and in Turkey for the sake of its volatile oil, which is much employed for the adulteration of the otto of roses. According to Guibourt, three species of *Pelargonium* yield a volatile oil by distillation, closely analogous in odor to that of the rose: the species above named, *P. capitatum*, Soland., and *P. roseum*, Willd. (*Hist. Nat. des Drogues*, 4é ed., iii. 52.) The oil is obtained from the leaves. Recluz obtained from thirty-five ounces of *P. odoratissimum*, W., two drachms of a volatile, crystallizable oil. (Mérat and De Lens, *Dict. de Mat. Méd.*, iii. 368.) According to Septimus Piesse, one cwt. yields about two ounces. (See *A. J. P.*, xxvi. 368.) The oil which occurs in commerce, purporting to be the oil of *P. odoratissimum*, is perfectly fluid at ordinary temperatures, of a pale brownish-yellow color, and the characteristic odor of the plant, recalling merely that of the rose. This oil is now much used in perfumery. Piesse states that, as this oil is used to adulterate that of roses, so is it in its turn adulterated with the cheaper oil of *Andropogon Nardus*, L., cultivated in the Moluccas. (*A. J. P.*, xxvi. 368.) It appears, however, that the oil known as oil of *palmarosa* is the product of *Andropogon Schoenanthus*, L., distilled in India, and this oil is used most largely to adulterate oil of rose and oil of rose geranium. According to Baur, the oil is shipped in large copper flasks from Bombay to the Red Sea, and thence to Constantinople and Kizanlik. Jallard states that the true oil of rose geranium from *P. roseum* is freely soluble in 70 per cent. alcohol. The oils likely to be used to adulterate it are insoluble in this liquid. If, therefore, six drops of the suspected oil be mixed with 5 Cc. of 70 per cent. alcohol, there should be no separation. (*A. J. P.*, 1878, 280; from *J. P. C.*) F. W. Semmler (*Ber. d. Chem. Ges.*, xxiii. 1098) has shown that the chief ingredient in the various geranium oils is an alcohol, *geraniol*, $C_{10}H_{18}O$, which boils at from 231° to 232° C. (447.8°–449.6° F.), and has a sp. gr. 0.884 at 15° C. (59° F.). When oxidized by chromium trioxide mixtures, it is changed into *citral*, $C_{10}H_{16}O$, an aldehyde found in many of the essential oils, and this when oxidized by silver oxide yields *geranic acid*, $C_{10}H_{16}O_2$. The geraniol is both free and combined as *tiglic acid ester*. The oil also contains citronellol. (*Schim. Rep.*, April, 1897.)

Pengawar Djambi. *Paku Kidang*.—This is composed of silky, long, yellow or brownish hairs, very soft, which are obtained in Sumatra from the rhizomes of various ferns, especially of species of the genus *Cibotium*, especially *C. djambianum*, Hassk., *C. Barometz*, J. Sm., and *C. glaucescens*, Kze. It has the power of causing rapid coagulation of blood, and, when properly used, of mechanically arresting hemorrhages from capillaries. It has been much used in the physiological laboratories of Europe and this country, and was employed in human medicine during the Middle Ages under the name of *Agnus Scythicus*. The mediæval drug was composed of pieces of the rhizome with the attached scales and petioles so cut as to resemble animals. Attention has been called to the Pengawar Djambi on account of the assertions of Junker of its usefulness during the Franco-German war. (*L. M. R.*, Dec. 1887.) It is undoubtedly a very efficient styptic.

Pental. *Tri-methyl-ethylene*. *Isoamylene*. $(CH_3)_5C:CH_2$.—A hydrocarbon prepared by distilling amyl alcohol with zinc chloride and treating the distillate with sulphuric acid. A colorless liquid, sp. gr. 0.6783, boiling at 38° C. (100.4° F.), insoluble in water, and miscible with alcohol, ether, and chloroform. It was proposed as an anæsthetic, but is probably of very little value in medicine.

Pentaclethra. *Pentaclethra macrophylla*. The nuts of this plant, which grows in the Congo States, are said to contain an alkaloid, *paucin*, crystallizing in yellow foliaceous crystals, melting at 126° C. (258.8° F.), insoluble in ether and chloroform, having the formula $C_{27}H_{39}N_5O_5$. (*P. J.*, lix.)

Peptones.—The general name of a class of albuminoids into which the nitrogenous elements of food (such as albumin, fibrin, casein, etc.,) are converted by the action of the gastric or pancreatic juices. This conversion is caused by the ferment pepsin, normally present in the gastric juice, but used to produce peptones on a large scale for food and medicinal uses, and also by trypsin present in the pancreatic juice.

Peptones are not precipitated by potassium ferrocyanide in the presence of acetic acid like other proteids, and are not coagulated by heat. They are readily assimilated by the intestinal mucous membrane and peptonized meats are used as a nutritive medicine.

Perezia Root.—This root is obtained from several Mexican plants, *Perezia Wrightii*, A. Gray, *P. Nana*, A. Gray, and *P. Dugesii*, A. Gray. (Fam. Compositæ.) It contains *pipitzahoic acid*, a substance which crystallizes in beautiful golden-yellow needles. R. Anschütz and J. W. Leather obtained from the dried roots of *P. adnata*, A. Gray (*Trixis Pipitzahoac*, Schaffner), an average of 3.6 per cent. of this acid, which melts at from 103° to 104° C. (217.4°–219.2° F.), sublimes readily, and is easily soluble in alcohol, ether, chloroform, benzene, and glacial acetic acid. The authors confirm the formula given to the acid in 1855,—viz., $C_{15}H_{20}O_8$. It is a quinone, and bears great resemblance, when recrystallized from diluted alcohol, to *oxythymoquinone*, which, recrystallized from the same liquid, is scarcely distinguishable from it. (*A. J. P.*, 1884, 185, and *Ph. Rund.*, 1883, 245; *A. Pharm.*, 1887, 183.)

Under the name of *perezol* the 0.5 per cent. alcoholic solution of *pipitzahoic acid* has been recommended by Duyk as an alkalimetric indicator. By acids it is at once decolorized; with alkalis

it becomes reddish. Boric, and perhaps other acids, and acetates, borates, bicarbonates, and carbonates act with respect to the solution like alkalies.

Periploca. *Periploca graca*, L.—From the bark of this asclepiadaceous plant, growing in the neighborhood of the Black Sea, has been separated by Lehmann and Burschinski (*A. Pharm.*, 1897) a colorless crystalline glucoside, *periplocin*, soluble in 125 parts of water, freely soluble in alcohol. According to the experiments of Lehmann and Burschinski, it is an active cardiac poison belonging to the digitalis group.

Peronine. *Peronin*. $C_{17}H_{18}NO_2 \cdot O.C_6H_5CH_2$ HCl.—This is the hydrochloride of morphine benzyl-ester, produced by replacing the hydrogen of the hydroxyl group in morphine, which is analogous to the hydroxyl group of phenols, with the alcohol radical ($C_6H_5CH_2$). Peronine occurs as a bitter, odorless white powder, consisting of prismatic crystals. At $65.5^\circ C.$ ($150^\circ F.$) it dissolves in water in the proportion of 7.5 to 1000, but dissolves readily in 10 parts of boiling water, the aqueous solutions having a bitter taste and being neutral to litmus. It is further soluble in 218 parts of 95 per cent. alcohol, in 100 parts of methyl alcohol, and in 390 parts of chloroform. Although precipitated from its solutions by the general alkaloidal reagents, peronine differs both in its solubilities, and also in its behavior towards special reagents, from morphine and codeine.

Peronine was first therapeutically investigated by Schröder (*Th. M.*, 1897), and the conclusion reached that in its medicinal activities it is intermediate between morphine and codeine. Reports have been made upon it by Nowak (*Ther. Woch.*, 1897), by Munk (*Aerzt. Central-Anzeiger*, 1897), and by Ebersson (*Th. M.*, 1897). The physiological action of the drug has been partially studied by Mayor (*Revue Méd. de la Suisse Romande*, 1898), who finds that it produces in guinea pigs and rabbits exaggerated reflexes, ending, if the dose have been large enough, in convulsions and death by asphyxia. The lethal dose for rabbits, according to Mayor, is 2.5 Gm. per kilo, or little less than one-third that of codeine. On the other hand, Pierart affirms, as the result of his experiments, that peronine is more poisonous than morphine. Clinically, peronine has been used to some extent as a substitute for morphine, having analgesic and hypnotic powers inferior to those of that alkaloid, but being of distinct value in the treatment of *phthisis*, *chronic bronchitis*, and other pulmonary diseases. The dose is from one-third of a grain to one grain (0.021–0.065 Gm.). Given during the day in the smallest dose mentioned, every five to six hours, in cases with severe cough, it is said to act most favorably in producing comfort during the day and rest at night.

According to Bufalini, confirmed by Gevaert, the 1 to 2 per cent. solution of peronine placed in the conjunctival sac produces a complete anæsthesia which lasts for many hours. The drug, however, probably has no practical value on account of its causing pain, oedematous swelling, and even serous chemosis of the conjunctiva.

Persulphates.—Persulphates are obtained by the electrolysis of solutions of sulphates. Sulphuric acid is decomposed into H_2 and SO_4 and the SO_4 ion unites with a molecule of the normal sulphate, as:

They have been brought forward for use in medicine and dentistry on account of their yielding oxygen when heated and their germicidal properties.

According to Friedländer (*Th. M.*, Feb. 1899), the half per cent. aqueous solution checks the growth of pathogenic bacteria, and the 5 per cent. solution kills them. They are said to be actively poisonous, 0.5 gramme per kilo rapidly causing death in the rabbit, and to be violently irritant to mucous membranes; one and one-half to five per cent. solutions have been used to some extent in the dressing of wounds.

The important persulphates are *ammonium persulphate*, $(NH_4)_2S_2O_8$, which occurs in colorless crystals, making a turbid solution with water; the *potassium persulphate*, $K_2S_2O_8$, which occurs in colorless crystals, very slightly soluble in water; and the *sodium persulphate*, $Na_2S_2O_8$, a colorless crystalline powder, sparingly soluble in water.

The *ammonium persulphate* has been strongly recommended by Strzyzowski (*Schweizer Wochenf. Chemis. u. Pharmacie*, 1898, No. 48) as a urinary reagent; if its ten per cent. solution is allowed to fall into a test tube containing urine the presence of albumin will be revealed by a whitish-gray zone at the juncture of the two liquids. The development of a green tint indicates the presence of biliary pigments.

Löwenberg prepares *sodium persulphate* as follows: A concentrated solution of sodium sulphate and a diluted solution of sulphuric acid, separated from each other by a porous diaphragm—a clay cylinder—are so arranged that the positive pole of an electric battery dips into the saline solution in form of platinum wire, while the negative pole is joined to a sheet of platinum immersed in the acid solution. By electrolysis sodium persulphate ($Na_2S_2O_8$) is formed in the saline solution, a necessary precaution being that the solution be neutralized from time to time so as to overcome too great acidity—sodium sulphate being then simultaneously produced for the next operation. The sodium persulphate so obtained is not absolutely pure, usually containing several per cent. of sodium sulphate. It is a white, crystalline, odorless powder, which when heated in the presence of water easily decomposes, thus:

Its therapeutic energy depends upon the production of free sulphuric acid and oxygen. The salt is readily soluble in water, and its solutions keep unchanged for weeks unless they be heated or in contact with easily oxidizable bodies. (*Th. M.*, 1899, 99.)

Sodium persulphate has been recommended internally as an aperitive stimulant to digestion, in *hypochondria*, *chlorosis*, *neurasthenia*, and various other conditions. The dose in a day is three and one-half grains (0.23 Gm.).

Persodine is the one and three-tenths aqueous solution which has been supplied commercially in France.

Peruol.—This is a twenty-five per cent. solution in castor oil of *peruscabine*, the active principle of Peruvian balsam, which has been produced synthetically by Erdmann. Peruscabine itself is pure *benzoic benzyl-ester* and is a colorless oil, boiling at $173^\circ C.$ ($343.4^\circ F.$). It has been used in skin diseases and is said to be especially valuable in *scabies* and in *mange*. The whole or a part of the body should be freely anointed with some friction three or four times in thirty-six hours, and after a day or more a soap bath given.

Petroleum. *Rock Oil.* *Oleum Petró.* *Coal Oil.* *Pétrole.* *Huile minérale.* Fr. *Bergöl.* G. Petroleum is a native mixture of hydrocarbons

with very small amounts of oxidation or alteration products admixed. The hydrocarbons may be gaseous, liquid, or solid, and in crude oil, fresh from the wells, all three classes are present. The hydrocarbons belong to several of the homologous series known to organic chemistry. The researches of Pelouze and Cahours, of Warren, and more especially of Schorlemmer, have established the presence of the paraffin series, C_nH_{2n+2} , beginning at methane and continuing through the liquid members, which constitute the bulk of the oil, to the solid hydrocarbons known commercially as "paraffine;" of the olein series, C_nH_{2n} ; of the benzene series, C_nH_{2n-6} . After the oil has been heated, as in distillation, pyrogenic products form, so that in the residues of petroleum distillation, naphthalene, anthracene, and other higher hydrocarbons have been detected. In Caucasian petroleum, Beilstein and Kurbatow (*A. J. P.*, 1880, 612) have also found another homologous series of hydrocarbons, *hexahydrobenzene*, C_6H_{12} , and its homologues known as the *naphthenes*.

Pennsylvania petroleum consists, however, chiefly of paraffins, and the individual hydrocarbon making the bulk of illuminating oil is *heptane*, C_7H_{16} . The oxidation products accompanying petroleum constitute only a small fraction of 1 per cent. usually, and have not been very fully studied. It is known, however, that these alteration products are largely acid in character. Prolonged atmospheric exposure may, however, cause a petroleum to thicken, at least superficially. In this way the semi-solid deposits of California are explained, as well as Rangoon tar and Trinidad pitch or bitumen. When the bitumen is in the solid state it is called *asphaltum*. This is black, dry, friable, and insoluble in water or alcohol. Not infrequently asphaltum exists in nature mixed with more or less of the liquid substance, and this semi-solid mixture is distinguished by the name of *maltha* or *mineral tar*.

Petroleum has been known from the earliest historical period. Within the limits of the United States it has long been known to exist in a few localities. On the borders of Seneca Lake in the State of New York small quantities of it were collected, and to some extent used in medicine under the name of *Seneca oil*. In Western Pennsylvania, on Duck Creek in Ohio, near Scottsville in Kentucky, and on the Kanawha in Virginia it attracted local attention, and a certain locality in Western Canada had acquired some notoriety by its burning spring. But little attention was paid to it until the year 1859, when, the preparation of oil for burning, distilled from bituminous shales, having proved very profitable, and a strong resemblance having been shown to exist between this and petroleum, enterprise was directed towards some of the known sources of the latter liquid, and, being greatly stimulated by success, soon led to further and astonishing discoveries. At first the most productive locality of petroleum was in Western Pennsylvania; but it has been found to exist in great quantities elsewhere, and in fact occupies large portions of a region commencing in Western Canada, and extending, through New York and Pennsylvania, westward into Ohio and Kentucky, and far southward into West Virginia. After the Pennsylvania field, in order of development, is that of Ohio; but most of the oil produced in this State is from a different geological horizon,—viz., the Trenton limestone,—and contains a persistent sulphur impurity. This renders the Ohio oil (popularly

known also as *Lima oil*, from the town of Lima, Ohio) more difficult and expensive to refine. It is hence very largely used in the crude state as *fuel oil*, and as such has been of the greatest industrial value, being shipped by pipe line or tank cars to great distances. Within recent years large quantities of petroleum have been found in California, Texas, Louisiana, Kentucky, and Kansas, but in the main it is of a grade much inferior to that known as Pennsylvania oil, being largely used as fuel oil.

In the early days of the petroleum discovery the oil was gathered as it floated on the surface of the water in springs or small streams. In 1859 the first oil well, the Drake well, was sunk near Titusville, Pa., and the oil-bearing strata were reached at a depth of seventy-one feet, with the result of some eight barrels per day. In 1861 and 1862 the first large flowing wells were struck in drilling for oil. The explanation of these flowing wells is simply that in new territory the gaseous hydrocarbons have accumulated with the liquid oil in such amount that they exert an enormous pressure, causing a flow of oil at the rate of two, three, and in one case as high as eight thousand barrels per day. Often, however, the pent up gas escapes with enormous force without any accompanying oil. These *gas wells*, as they are termed, are well known throughout the oil regions, and they have been utilized on a large scale as sources of gaseous fuel for manufacturing and domestic purposes. The statistics show that the value of the coal displaced by natural gas as fuel in 1903 was \$35,815,360, and in 1904, \$38,496,760. Of this amount nearly one-half was obtained in Pennsylvania, while Indiana, West Virginia, and Ohio followed in the order named. (*Mineral Resources of the U. S.*, Washington, 1904.) Sadtler has analyzed numerous samples of this natural gas, and finds it to consist chiefly of methane and its homologues, with traces of the olefines and of carbon monoxide. In one case free hydrogen was present. (*Proc. Amer. Philos. Soc.*, xvi. 585, 1877.) After a well has flowed oil for a time, it will continue to yield on pumping. Indeed, many smaller wells never have flowed, and have to be pumped from the start. In some districts "torpedoing" with nitroglycerin has been largely resorted to after a well has begun to decline in power, in order to increase the flow. The explosion effects this by shattering the sandstone and pebble conglomerate which holds the oil, so that new channels are opened.

Oil wells are of various depths. The first or Drake well, as stated, was only seventy-one feet deep, while in Butler County the fourth sand rock was reached only at a depth of from 1500 to 1800 feet, and in Washington County and other localities in the southwestern part of Pennsylvania the oil was obtained from a depth of 2000 feet.

There are two theories as to the origin of petroleum. According to one, it is simply a product of distillation from the bituminous shales which underlie almost the whole of this oil producing country. The gas and the liquid oil are equally products of this distillation. According to the other, it represents the decomposition of marine plants and animal life which accumulated in these sand rock formations. These decomposition products may have also been in part subjected to distillation.

Studies by Engler (*Ber. d. Chem. Ges.*, 1888, 1816) on the distillation under pressure (ten atmospheres) of fish oils and of olein and other

fats show that large amounts of light oils, composed of pentane, hexane, heptane, octane, and nonane, can be obtained, thus making the second theory very probable.

S. P. Sadtler (*Proc. Amer. Phil. Soc.*) has shown that linseed oil, distilled under pressure, may be made to yield hydrocarbons of the paraffin series, and has obtained products of all gravities from light benzin to solid scale paraffin. Thus, Engler's theory must be broadened sufficiently to allow of the vegetable seed oils being taken as original sources of petroleum production as well as animal oils.

Crude petroleum is occasionally of a clear color when taken from the earth, but is generally of a greenish color, appearing claret-red by transmitted light. The green color may, however, become so dark as to be almost black. In gravity it varies from 0.865 to 0.777, or from 32.5° to 52° Baumé.

The enormous production of crude petroleum in the last twenty-five years has had the effect of developing a variety of new industries connected with the working or shipping of it. The whole producing area of Western Pennsylvania and adjacent States is now covered with a net work of wrought iron pipes, for the conveyance of the oil; and these "pipe lines" now extend to Cleveland, Buffalo, Pittsburg, New York, Philadelphia, and Baltimore, so that crude oil is pumped from the vicinity of the wells to the seaboard cities, to be refined there or to be exported in bulk. The refining of crude oil, and the working up of the several liquid and solid products that are known commercially, are also immense industries. The production of crude petroleum for the year 1904 amounted to 120,000,000 barrels, of which 30,316, 328 barrels were what is known as Pennsylvania grade (produced in the Appalachian field), 21, 241,058 barrels of what is known as Lima oil (produced in Ohio and Indiana), 29,805,000 barrels in California, 19,500,000 barrels in Texas, 6, 600,000 barrels in Louisiana, 5,600,000 barrels in Kentucky, 5,600,000 barrels in Kansas, and 1,387, 614 barrels in other States. The exports of crude and refined petroleum for the year 1904 were: crude petroleum, 95,974,645 gals.; naphtha and light distillates, 22,837,347 gals.; illuminating oils, 745,742,071 gals.; lubricating oils and paraffin, 87,459,482 gals.; residuum, 33,736,412 gals.; total of all grades, 985,729,957 gals., valued at \$78,221,167.

After American petroleum the next in importance is Russian or Caucasian. The wells here, although only a few hundred feet in depth, are wonderfully prolific and are veritable "oil fountains." Two of them, the Droobja well and Nobel's No. 9, each yielded for a time nearly 48, 000 barrels of crude oil every twenty-four hours.

The method of purifying petroleum is analogous to that already described for purifying coal tar. The crude oil is put into large retorts of wrought iron and exposed to a heat rising gradually to between 315.5° C. (600° F.) and 426.6° C. (800° F.), by which all the volatile ingredients are distilled, leaving from five to ten per cent. of solid residue, constituting a sort of coke. The liquids thus obtained are comparatively colorless, though still retaining the strong odor of the crude oil. The several fractions are collected separately and show very varying gravity and volatility, and are applied to different uses. An average result of a normal distillation may be stated as follows: gasoline 1½ per cent., refined naphtha 10 per cent.,

benzin 4 per cent., refined petroleum or kerosene 55 per cent., lubricating oil 17½ per cent., paraffin 2 per cent., loss, gas, and coke 10 per cent. As the greater demand for illuminating oil makes it desirable to get the maximum quantity of this fraction, the distillation is generally so conducted that by the process of "cracking" the yield of burning oil is increased at the expense of the lubricating oil and heavy naphtha. Many distilleries obtain, therefore, from 75 to 80 per cent. of illuminating oil from the crude material. A crude distillate, however, would not be adapted for the purposes of an illuminating oil, so the distillate must be treated with acid. It is placed in the treating tank or "agitator" and 1 or 2 per cent. of strong sulphuric acid is added, when by the aid of an air blast introduced below the whole is violently agitated. The acid combines with the impurities of the oil and forms a tarry substance, called "sludge acid," which settles to the bottom, and after the whole has subsided is removed. The oil is then washed with water and again agitated, the process being repeated once or twice. It is then treated with caustic soda solution and again washed. The oil is now clear and almost colorless. It is then placed in large settling tanks to allow the water to separate. If it does not have the desired fire test, it is "steam stilled" and the lighter vapors taken out until the desired test is obtained. In most States of the Union the legal fire test for illuminating oil is 110° F. (43.3° C.); that is, it must not evolve inflammable vapors below the temperature of 110° F. (43.3° C.). Many special brands of illuminating oil have a much higher fire test, as high even as 300° F. (148.8° C.).

Lubricating oils, on the other hand, are valued according to their "cold test;" that is, they must not congeal except at very low temperatures. A lubricating oil, therefore, consists of the heavy liquid hydrocarbons of the paraffin and olefin series, but is free from the solid paraffin.

Medicinal Properties and Uses.—Petroleum is accounted a stimulating antispasmodic, expectorant, and diaphoretic. In large quantities it may prove poisonous, as shown by a case recorded in the *J. P. C.* (Mars, 1869, 227), in which, after swallowing by mistake a quantity of rectified petroleum, a workman was seized almost immediately with violent inflammation of the throat, with colicky pain, and a desire to vomit, followed in an instant by a fearful tetanic seizure, and a general rigidity, attended by the most frightful cries. After a relaxation of ten minutes the symptoms returned with still greater violence; and life was probably saved only through the prompt action of the powerful emeto-cathartic medicines administered. It is occasionally given in disorders of the chest, when not attended by inflammation. In Germany it has been extolled as a remedy for *tape worm*. Schwartz's formula in such cases was a mixture of one part of petroleum with one and a half parts of tincture of asafetida, of which forty drops were given three times a day. Externally, petroleum is employed in *chilblains*, *chronic rheumatism*, affections of the joints, *paralysis*, and diseases of the skin, and is said to be very effectual in *psora* and *prurigo*. (See *Petrolatum*, p. 922.) It also affords a good antiseptic dressing for wounds. (*M. T. G.*, 1870, 101.) It is an ingredient in the popular remedy called *British Oil*. The dose of petroleum is from thirty drops to a teaspoonful, given in any convenient vehicle. Crude petroleum is used to a

considerable extent as an external application in domestic practice. The finer kinds of petroleum have been used with alleged advantage in *cholera* by Andreosky of the Russian army, by Cloquet, physician to the Shah of Persia, and by Moretin of France. They gave from ten to twenty drops in half a glass of white wine or mint water. It is affirmed that many cases of *asthma* are much benefited by inhaling petroleum vapors.

Petrosapol.—This is a brown ointment-like compound of soap and the by-products of petroleum; especially used as a vehicle for ointments. It does not melt below 90° C. (194° F.) and does not therefore liquefy on the skin.

Petrosulfol.—This is said to be an ichthyol-like compound useful as a local remedy in *eczema* and allied diseases.

Peucedanum. *Chuoklusa.*—Two North American species of this genus, of the fam. Umbelliferae, are used by the Western Indians as food. For an account of them, with analysis, see A. J. P., 1890. They contain *peucedanine*.

Peucedanum palustre (L.), Michx. (*Selinum palustre*, L.) Marsh Parsley. Marsh Smalage. *Persil de Marais*, Fr. *Radia Olsnitii*. *Sumpfsilge*, *Elsenich*, G.—The root of this European umbellifer is, when dried, of a brown color externally, having a strong aromatic odor, and an acrid, pungent, aromatic taste. Peschier found it to contain a volatile oil, a fixed oil, and a peculiar acid which he calls *selinic*. It has been used for *epilepsy* in Russia. *Dose*, from twenty to thirty grains (1.3–2.0 Gm.) thrice daily, rapidly increased to four times the amount. (J. P. C., 1859.)

Pharbitis.—A genus constituted by Choisy, 1833, its species referable to *Ipomoea* or *Convolvulus*. *Ipomoea hederacea* (L.), Jacq. (*Convolvulus hederaceus*, L., *Pharbitis Nil*, Choisy, *P. triloba*, Miq.). The seeds of the Japanese convolvulaceous plant *P. triloba* have been chemically examined by K. Hirano and also by Y. Inoko, who find that they contain a large proportion of a resinous substance, seemingly identical with *convolvulin*, and acting as a cathartic in doses of from seven to ten grains (0.45–0.65 Gm.). (*Sei-i-kwai*, 1891.)

Phaseolus. *Phaseolus vulgaris*, L. *Common Bean*. (Fam. Leguminosae.)—Soltzien found an alkaloid, *phaseoline*, in the legumes of the common bean. He, during a toxicological analysis, traced the source of the alkaloid which might, under other circumstances, have been mistaken for a ptomaine, to the beans found in the stomach under examination. The new substance is not crystallizable in the free state, but it crystallizes as a hydrochloride. (A. Pharm., 1884.)

Phenalgin. *Ammonio-phenylacetamide*.—This is a white salt, having a peculiar mild, somewhat ammoniacal taste, forming with water an alkaline solution, and when warmed with strong nitric acid emitting dense ruddy nitric fumes, giving a solution resembling that of picric acid. It is now recognized to be a mixture of acetanilide, sodium bicarbonate, and ammonium carbonate of varying composition. It is asserted to be an analgesic, especially useful in *dysmenorrhoea*, also anti-rheumatic, and by virtue of its ammonia to act as a vascular stimulant. It is evident, however, that the effect of the ammonia which it contains must be very transient and unimportant. *Dose*, from three to twenty grains (0.2–1.3 Gm.).

Phenatol.—An antipyretic, said to be a mixture of acetanilide, caffeine, sodium bicarbonate, carbonate, chloride, and sulphate. (*Ph. Ztg.*, 1894, 784.)

Phenocoll Hydrochloride. *Amido-aceto-para-phenetidin-hydrochloride*. *Glycocoll-para-phenetidin-hydrochloride*. $C_6H_4 \begin{cases} OC_2H_5 \\ NH.COCH_2.NH_2.HCl. \end{cases}$

This is formed by the action of glycocoll (amido-acetic acid) upon phenetidin. It is a white finely crystalline powder, soluble at 17° C. (62.6° F.) in sixteen parts of water; also soluble in warm alcohol. Ammonia, alkalies, and alkaline carbonates throw down the pure base phenocoll from the solution of the hydrochloride, in the form of white needles with one molecule of water of crystallization.

According to Kobert, the phenocoll hydrochloride is scarcely at all poisonous to the lower animals, and does not alter the constitution of the blood. Von Mering found that twenty-three grains could be given to the rabbit without the production of any symptoms. Further experimental research is, however, necessary before any conclusions as to the action of phenocoll can be reached, since I. Ott has found that in frogs it is paralyzant to the cerebrospinal axis, while in rabbits it produces cyanosis, reduces the force and frequency of the heart's action, and kills by centric respiratory paralysis. W. S. Carter and D. Cerna found that while ordinary doses do not affect the circulation, toxic doses lessen blood pressure by a direct action on the heart, and first stimulate and then paralyze the cardiac inhibitory system. Oby failed to get any action upon the blood itself. The fall of temperature produced by it is said to be due to lessened heat production. Hertel (*D. M. W.*, 1891) and Herzog (*Ibid.*) find that phenocoll in man usually produces no gastro-intestinal irritation or other disagreeable symptoms; that its antipyretic action, when given in doses of a gramme, is a quick, certain one; and that it acts well even in the *hectic fever of phthisis*. It is apt to cause considerable sweating, which can be prevented, however, by the administration of minute doses of atropine. During the taking of the drug the urine becomes of a dark reddish-brown color, but does not contain albumin; both indican and biliary substances have been noted. The observers also noticed the remedy to act very well both in acute and chronic *rheumatism*. The first reports of Hertel, so far as concerns the antipyretic influence of the drug, have been generally confirmed by clinicians, but numerous reports state that as an antirheumatic or antineuralgic phenocoll is inferior. Active antiperiodic powers are attributed to it, and both in Algiers and in Italy it has been used to a considerable extent in *malarial fevers*. As much as seventy-seven grains (5 Gm.) a day have been given without evil results, and in cases of rheumatism less than this amount usually fails to accomplish good results. Cohnheim found that phenocoll appears in the urine in one hour, and can still be recognized nine hours after its ingestion by the ferric chloride test. The *dose* is from eight to twelve grains (0.5–0.78 Gm.). It is best given in capsules.

Salocoll, Phenocoll Salicylate,

$C_6H_4 \begin{cases} OC_2H_5 \\ NH.COCH_2.NH_2.C_6H_4(OH).COOH \end{cases}$ has been put upon the market as an antirheumatic. It may be used in the same doses as phenocoll.

Phenol-Bismuth. $Bi(OH)_3(C_6H_5O)_3$.—This is a white, neutral, non-irritant and non-toxic powder, almost odorless and tasteless, which, according to its manufacturer, contains 80 per cent. of bismuth in chemical combination with 19 per

cent. of phenol. It is stated by M. F. A. Jasenski to be decomposed in the gastro-intestinal tract, with absorption of the phenol and escape of the bismuth, in great part with the feces. It is also asserted by Jasenski that even the largest doses (seventy-five grains) of it produce no evidences of phenol poisoning, and the probabilities are that but a small portion of the compound suffers decomposition in the intestinal tract. It has been used in doses of from eight to thirty grains (0.5–2.0 Gm.) in all forms of gastro-intestinal catarrhs, fermentative dyspepsias, and similar complaints, as an antiseptic; also to some extent locally in various mucous inflammations.

A coal tar product used as an indicator in volumetric analysis. It occurs in colorless powder almost insoluble in water, soluble in alcohol and in alkalies, with which latter it yields a fine red color, disappearing on addition of excess of acid.

According to the experiments of Oscar Schwarz (*M. M. W.*, June, 1903), phenolphthalein is converted in the intestines into sodium salt, which has little diffusibility and is therefore only in very small part absorbed, so that out of a dose of 3 grammes given to the dog 2.55 grammes were recovered from the stools; 10-gramme doses of phenolphthalein have no distinct effect on the elimination of the sulphates in the dog, so there can be little or no decomposition with elimination of phenol in the system. *Purgen*, said to be essentially phenolphthalein, is affirmed to be a useful laxative. *Dose*, for children, two-fifths to five-sixths grain (0.025–0.05 Gm.); for adults, one to five grains (0.065–0.32 Gm.).

Phenosal. *Phenetidin Salicylate.*

$C_6H_4 \begin{array}{c} \diagup OC_2H_5 \\ \diagdown NH.CO.CH_2.OC_6H_4.COOH \end{array}$ It forms colorless crystals of acidulous taste, difficultly soluble in water. Phenosal is said to contain 57 per cent. of phenacetin and 43 per cent. of salicylic acid; to be decomposed into its constituents in the alimentary canal, and to be a useful remedy in the treatment of rheumatism, and also of tabetic and other nerve pains. *Dose*, eight grains (0.5 Gm.).

Phenosalyl.—An antiseptic mixture composed of phenol 9 Gm., salicylic acid 1 Gm., lactic acid 2 Gm., menthol 0.10 Gm., and at times benzoic acid and sodium glyceroborate and other ingredients. It has been used in aqueous solution to sterilize tuberculous expectorations.

Phenylchinaldine. *Phenylquinaldine.*—*Methylquinol*, $C_{10}H_9(C_6H_5)_2N$, is prepared by the action of hydrochloric acid on a mixture of aniline, acetophenone, and aldehyde. The hydrochloride occurs in colorless crystals, which are readily soluble. It forms with sulphuric acid a crystalline salt, easily soluble in water, with a feebly acid reaction. Leo Fürbringer (*Deutsch. Arch. f. klin. Med.*, lix, 1897) finds that it produces in the lower animals tremors, violent cramps, fall of temperature, and death (if the dose has been large enough) from failure of respiration. The fatal dose to the rabbit is about fifteen grains (1 Gm.). It has been used by Julius Mannaberg in malarial fever in the dose of eight grains (0.5 Gm.) three times a day, but found to be much inferior to quinine.

Phenylchinaldine. *Phenylquinoline.* $C_9H_8(C_6H_5)_2N$.—According to Tappeiner (*Deutsch. Arch. für klin. Med.*, lvi, 1896), the action of this substance on the lower organisms is almost identical with that of quinine and about equal to it in strength.

Phenylenediamine. $C_6H_4(NH_2)_2$.—*Para-phenylenediamine* and *meta-phenylenediamine* have been physiologically studied by Dubois and Vignon (*C. R. A. S.*, cvii, 533), who find that in doses of 0.01 Gm. per kilogramme they cause in the dog vomiting, diarrhoea, and fatal coma, with peculiar symptoms.

Phenylhydrazine. $C_6H_5.NH.NH_2$.—This is prepared from diazobenzene hydrochloride (resulting from the action of sodium nitrite upon aniline hydrochloride) by reduction with stannous chloride or sodium sulphite. It is a colorless, peculiar-smelling oil solidifying to plate-like crystals melting at 23° C. (73.4° F.); difficultly soluble in water; easily soluble in alcohol and ether. The various compound derivatives of this substance have been tested by Heinz (*B. K. W.*, 1890) and others, and found to be too toxic for use in practical medicine. Phenylhydrazine itself has been employed in the following manner as a test for sugar in the urine. (*Fischer's Test*.) "To 8 Cc. (120 min.) of the urine, add 1 Cc. of normal solution of barium chloride with a few drops of solution of potassium hydroxide; filter, add 0.2 Gm. (3 grains) of sodium carbonate, heat to boiling, and filter. To the filtrate add 2 Cc. (30 minims) of acetic acid (36 per cent.), and about 0.1 Gm. (1½ grains) of phenylhydrazine hydrochloride, evaporate the solution on the water-bath to one-half its volume." An amorphous precipitate will be formed if only a small quantity of sugar be present, but if the sugar be present in considerable quantity a precipitate of minute yellow needles will be deposited. This test was discovered by Emil Fischer, and is founded on the property of glucose in the urine forming with phenylhydrazine, crystals of phenylglucosazone.

Phenylhydrazine is an active irritant and toxic agent, producing in warm blooded animals violent disturbances of breathing, with gastro-enteritis. It is remarkable for the changes which it produces in the blood, causing that fluid to become of a distinct green color when seen in thin sheets. The coloring matter appears not to be due to a derivative of phenylhydrazine, but to have at least spectroscopic relations to acid hæmatoporphyrin and to chlorophyll. (See *Z. B.*, N. F., xxiv, 1901.)
